Proceeding next to give a brief outline of the annual circuit along which aphid life runs, I have to remark that though several naturalists who were his predecessors in the study of the habits of aphides had observed the presence of wingless females in great numbers, either alone or in company with the winged, Charles Bonnet, who published his discoveries in 1745, was the first to see and record the astonishing fact that successive generations of aphides appear through the summer, all of which are females. He pursued the rearing of the insects in confinement for five generations, and other entomologists have found that brood after brood, under certain

conditions, can be produced beyond that point without the intervention of the males. How many broods annually follow each other when the insects are at large will depend on the weather, and also there are differences in the species, some being marvellously prolific. Bonnet had several individuals which gave birth to others when they were twelve days old, and though this need not be regarded as representing an average state of things, no doubt from May to September there are many successive broods of aphides, the bulk of them wingless; but winged aphides, almost invariably female, do show themselves from time to time—in fact, on any day during the summer we may see winged specimens on some plant or another. It is not necessary to show by argument that wings mean flight, therefore it follows that there are constantly aphides passing through the air, though May or June, the time varying with the wind and weather, are especially the months for aphid migration. The statement formerly made that flights of these insects only took place in the spring and autumn is not strictly true, though it may be correct as to some species. During the autumn, however, males appear in company with the females, eggs are deposited on the twigs and stems, and these generally remain unhatched for seven or even eight months. According to the observations of Mr. Walker in a few instances impregnated females live through the winter, laying in the spring.—J. R. S. C.

## ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 6TH.

**FRUIT COMMITTEE.**—Henry Webb, Esq., in the chair.—Mr. G. T. Miles, gardener to Lord Carington, Wycombe Abbey Gardens, sent a dish of Early Crawford Peaches from the open wall. The weight of the six was 3 lbs. They were well-ripened, fine-looking fruit, and well deserved the cultural commendation voted to them. Mr. A. Offer, Felcourt Gardens, East Grinstead, sent a white-fleshed Melon that had been raised from seeds sent from Greece, but it was worthless; also a large variety named Felcourt Green-flesh Melon from an English variety crossed with the Grecian sort, but it was not well flavoured. Mr. W. Turner, gardener to W. Knowles, Esq., Streatham, Surrey, sent a Pine that had been raised from imported crowns. The fruit was very juicy, but of inferior flavour. A letter of thanks was voted. Col. R. H. Clarke sent fruit of Fig de l'Archipel from the open wall. It was of large size and fair flavour. A letter of thanks was voted. Nine varieties of Dwarf Kidney Beans were sent from the Society's gardens at Chiswick, including Canadian Wonder, Fulmer's Forcing, Scarlet Flagelot, Crimson Flagelot, Nain Blanc Quarantin, Advancer, Pheasant's-eyed, and Yellow Champion.

Messrs. Carter & Co., High Holborn, London, offered prizes for a dish of their new Green Gage Tomato. Sixteen dishes were staged in competition. The first prize went to Mr. J. Douglas, gardener to Francis Whitbourn, Esq., Loxford Hall, Ilford; he had very fine examples, large in size and perfectly round. Mr. J. Morgan, gardener to Major Scott, Wray Park, Reigate, was second with well-ripened fruit, but smaller; Mr. R. Brown, gardener to F. T. Barry, Esq., Clock House, Beckenham, was third also with very fine fruit. These Tomatoes made a very fine display, and the variety is one that is worthy of general cultivation.

**FLORAL COMMITTEE.**—W. B. Kellock, Esq., in the chair. The Council-room was made gay on this occasion by the boxes of Quilled Asters which were entered in competition for the prizes offered by Messrs. James Carter & Co.; by large exhibitions of Dahlias from Mr. Turner, Slough, and Mr. Keynes, Salisbury, and a few interesting plants. Amongst the Dahlias exhibited by Mr. Keynes three obtained first-class certificates—namely, John William Lord, orange scarlet, large, full, and cupped; Minnie Bond, cream, tipped with purplish lilac, but too open in the petals; and Mrs. J. Downie, a beautifully formed and highly symmetrical flower, white, heavily tipped with lilac, very attractive and good. Ada Radford, deep peach colour, was very attractive in the collection.

Mr. Turner's collection of Dahlias was very large, and a vote of thanks was awarded. For Figaro a first-class certificate was awarded. It is a well-formed flower with great smoothness of petal and of an orange vermillion colour, the orange predominating in the centre of the petals; it is very full and good. A similar award was also made to Earl of Beaconsfield, a rather small but very full flower of a deep rich maroon colour—one of the finest of very dark Dahlias. In this collection were fine blooms of the new variety Drake Lewis, the finest of all scarlet Dahlias. Another particularly charming flower in the collection was Heather Bell, lilac peach colour, very distinct and attractive; Burgundy, Claret Cup, and Christopher Ridley, a small but very full red variety, also attracted notice. A stand of twelve very fine varieties consisted of Flag of Truce, Baroness Smith, Jas. Hunter, John N. Keynes, John Standish, Countess

of Pembroke, Jas. Cocker, Memorial, Jas. Service, Harriet Tetterill, Mrs. Stancombe, and Sir G. Smith. Mr. Turner also staged a collection of Pompon Dahlias, and received a vote of thanks. There were twenty-four varieties, the whole of which were good.

A first-class certificate was awarded to G. F. Wilson, Esq., F.R.S., for Liliun neilgherriense, a grand flower, having smooth, massive, and gracefully recurved petals. It is of a creamy white colour, deepening towards the centre. The flower is trumpet-shaped, and 8 inches in diameter exclusive of the petal's curve, and from its remarkable substance must be considered as one of the finest of recent introductions. It was discovered in the Neilgherries, and bulbs were distributed last year. Mr. Wilson had a second-class certificate for Lobelia subunda; it was not in flower, but it is very distinct, its foliage resembling that of a miniature Begonia, being velvety and clear in its venation. Mr. Wilson also exhibited Echeveria Murrayana from the Rocky Mountains. Splendidly cultivated plants of tuberous-rooted Begonias were exhibited by Messrs. E. & R. Perkins, Leamington. Excellent, a cross between Stella and Prestonensis superba, is a rich crimson scarlet, having very large flowers of great substance; Majesticum, a cross between Sedeni and Prestonensis superba, has still larger flowers of a warm cerise colour. These are splendid varieties of an attractive family of plants.

Mr. Cannell, The Nurseries, Swanley, Kent, sent double Pelargonium M. Buchner, purplish crimson, exceedingly rich, and received a first-class certificate; also Fuchsia Boliviana, a species having large crimson clusters of flowers; Aurora superba, distinct, by the orange tint of its corolla; Mrs. H. Cannell, the best of the double whites; and Erecta Von Novelty, a most profuse-flowering variety, with semi-upright flowers, with greenish white sepals and a lavender corolla, a fine bedding and decorative variety. Mr. Kingsbury, nurseryman, Southampton, exhibited double white Fuchsia Kingsburyana, very large and floriferous, but somewhat coarse, and a semi-double white variety with variegated foliage.

Mr. Noble, Bagshot, exhibited his new Rose Queen of Bedders, a most profuse and continuous-flowering variety, fully meriting its name. It is a seedling from Sir Joseph Paxton, and has been previously alluded to. Mr. Dean exhibited French Marigolds dwarf and floriferous, and a Potato grafted on the Tomato stock and producing tubers on the haulm; but we have heard of Potatoes indulging in the same freak when growing directly from the tuber. Mr. W. Chapman, gardener to E. Reeves, Esq., North-end Lodge, Fulham, exhibited Nerine curviflora major having an umbel of scarlet flowers; Colonel Clarke, Welton Place, Daventry, hybrid Begonias; and Mr. H. Mette, Quedlingburg, North Germany, Humea elegans alba.

The prizes offered by Messrs. James Carter & Co. for twenty-four blooms of Quilled Asters went in the following order: To Mr. Giles, Wickham, Newbury; Major Scott, Wray Park, Reigate; Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford; Mr. Morgan, jun., Dood's Road, Reigate; and Mr. Gaines, Fairley, Hampton Wick. The best collection was disqualified on account of flour having been used, ostensibly to change the yellow florets to white. Had this device not been resorted to Mr. Benham would easily have had the first place. The same exhibitor staged excellent flowers in other stands, as did also Messrs. Carter & Co., the latter being awarded a vote of thanks. The Asters exhibited were Princess Alexandra, Snowball, Purple Prince, and Prince of Novelties, and many of the blooms were very superior. There was a good attendance of horticulturists.

## NOTES AND GLEANINGS.

FROM many districts tidings have reached us of the SUPER-TUBERATION OF POTATOES. The crops had become partially ripened by the extreme heat, and since the rains have fallen are producing small young tubers. The value of such crops is greatly depreciated, the quantity of the first crop, or the crop proper, being inferior, and the tubers of the adventitious crops are, where large enough, only suitable for planting. Some may hesitate to plant these, but they are superior for that purpose to the tubers which first ripened. Fortunate are those who dug up their crops so soon as the tubers had attained to a fair size, for they have now produce of superior quality. A sample of Paterson's Victoria has been forwarded to us by Mr. Luckhurst, from the crop which was taken up when the haulm was still green and when the skins slipped off the tubers. These tubers are of splendid quality, indeed they are as perfect as if they had ripened in a natural manner in the ground. Early lifting, with subsequent care in storing, are the only real means of escaping the disease and "second growth." It is a lesson, however, which the great body of Potato cultivators appear to be slow in learning.

—MR. F. HAWES, gardener to Mrs. Rhodes, Henerton, near Henley-on-Thames, has this year grown some of the

finest COCKSCOMBS that have come under our notice for some time. They are of two shades of colour, some being deep crimson, others scarlet. They are grown in pots varying from 8 to 12 inches in diameter. These plants are splendid examples of culture, the combs ranging from 20 to 30 inches across. They have taken first prize at the Reading Horticultural Society's Show—in fact, they have secured first honours wherever exhibited for the last sixteen or eighteen years by the same successful cultivator.

—“J. P.” writes as follows on the PREVENTION OF CELERY FLY:—“To Celery-growers it will no doubt be a boon to find a preventive for that terrible pest the Celery fly. I saw some Celery plants a short time ago in several stages of growth at Mr. Reeves's, Walham Green, looking remarkably well, and not an atom of this pest about any of the plants. Mr. Chapman, the manager, says it is accounted for by using brewers' hops, which can be obtained at a trifling expense. As soon as the seedlings are pricked out he carefully spreads a few of the hops between them, and when removed to the trenches he again places hops amongst the plants. The hops answer two purposes—the fly will not come near the Celery, and moisture is secured in the soil by the mulching.”

—Two large pavilions used for the Bolton Flower Show were blown down during the SEVERE GALE which prevailed on the 31st ult., and much damage was done to the plants and shrubs.

—A LADY writing from Paris states that “in consequence of the excessive HEAT many trees have cast their foliage, and since the late rains occurred have commenced growing again, some Chestnuts on the Boulevards being now in flower, and have quite a spring-like appearance.”

—“A. W., Lincoln,” writes:—The fickleness of our climate has seldom shown itself in such a marked manner as during the latter half of the preceding month. The average maximum temperature from the 7th to the 21st was 80°, the average minimum during the same period being 51°. On the 22nd the temperature fell to 39°; a week of raw boisterous weather followed, the thermometer falling on two occasions to 35°. Tender plants, such as Poinsettias, were housed just before the change, and not a moment too soon, or they would have suffered irrecoverably.

—POISONING FROM LEAD IN VEGETABLES.—Dr. D. De Loos of Leyden writes in the “Weekblad van her nederlandsch Tijdschrift voor Geneeskunde” that he was consulted in October last regarding certain symptoms of paralysis and nervous disturbance which suggested the idea of lead-poisoning. The symptoms occurred in a family residing in the neighbourhood of a place where a manufactory of white lead had stood twelve years previously. They made use of vegetables growing on the spot. In order to make it certain that the poisoning was produced, as he believed it to be, by the vegetables, Dr. De Loos examined chemically some red Beet, Endive, and Carrots, and ascertained the presence of lead in all. In a Beet weighing 650 grammes he found the equivalent of a centigramme of metallic lead; in another of about the same size  $\frac{1}{2}$  centigramme; in six Carrots, weighing altogether 272 grammes, there were  $\frac{1}{2}$  centigrammes of metallic lead; and the metal was also found in the Endive. The ashes of the plants also contained traces of copper, which had probably existed as an impurity of the lead.—(*British Medical Journal*.)

—HUMPHREY REPTON, the writer on landscape gardening, was buried at Aylsham in Norfolk, and the following is his epitaph inserted in the wall of the church close to the chancel door:—

“Not, like Egyptian tyrants, consecrate,  
Unmixed with others, shall my dust remain;  
But blending, mould'ring, sinking into earth,  
Mine shall give form and colour to the Rose;  
And while its vivid blossoms cheer mankind,  
Its fragrant odours shall ascend to heaven!”

A small railed-in garden is in front of the tablet, and this garden is always kept bright and orderly by cousins of Mr. Repton, who live in Aylsham.

—THE HEAT IN INDIA has this year been excessive. Long after sunset the thermometer registered over 100° Fahr. in rooms in which the air was agitated by punkahs, and in some of the hospitals it has stood at 100° for many days, scarcely falling even at night.

—POPULAR impressions are often far from the truth, and in regard to the Arctic regions they are undoubtedly so. A TREELESS LAND would be, in the opinion of most people, the

idea which would suggest itself in regard to the regions in question. Yet this, though true, is not all the truth. Within the Arctic Circle are found trees often forming considerable though stunted forests. In Eastern Siberia Pines and other trees come down almost to the water's edge; while over all Western Siberia, Arctic Russia, and Lapland the tree limit runs within the Arctic Circle. Trees extend even to the North Cape. In Greenland we find, even in the most southerly parts of it, no herbage more worthy of the name of tree than the stunted Birch, which in the more sheltered valleys of that country—equally inappropriately named with Iceland—attain the proportion of little shrubs; and it is not until we come to the milder latitudes of the Pacific that the tree line, which had described a southerly curve in the cold regions of Central North America, again rises to the north, and until we reach the shores of Behrings Strait we find nothing which we can dignify by the name of trees. The wooded banks of the Yukon touch the Arctic Circle, and forests of white Spruce are found on the Noatak, a river which falls into Eschscholtz Bay, which infringes on the Arctic Circle. In Lapland the Spruce ceases at about the 68th parallel, and the Scotch Fir at the 69th; but in Norway, owing probably to the presence of the warm Gulf Stream, which sweeps along the coast and into the Arctic Sea—at least as far east as Novai Zemlai—we find forests of Scotch Firs 60 feet in height as far north as Altenfjord, and Birches about 45 feet high in an equally northern latitude. In latitude 70° 28' the hardy Scotch Fir still maintains its ground, though the Spruce fails a degree or so further south. In the vicinity of Hammerfest, a well-known Lapland town, in latitude 70½° N., there are dwarf Alders and Aspens, Cherries, Raspas, and Currants. In the Scandinavian peninsula, probably also owing to the warmth which a sea unencumbered, and in addition laved by a current of a higher temperature, affords, Barley is cultivated as far north as the 70th parallel, the latitude of Disco Island, on the Greenland coast, and Oats up to the 65th, “in sheltered valleys, where rocks and cliffs reflect the sun's rays with much power.”—(*Dr. Brown's The Countries of the World*.)

—THERE are at the present moment in Ceylon 257,000 acres of cultivated COFFEE, divided into slightly more than 1200 estates, and giving employment to 1050 managers and superintendents, nearly all of whom are Europeans. Some 50,000 acres of these estates are not in proper bearing through being either too young or too old, and therefore 210,000 acres may be taken as the extent of the plantations of the island, which are accountable for the present year's crop (ending in September), estimated at 630,000 cwts. Last year the yield, with 8000 acres less in cultivation, was 873,000 cwts. The value of the whole plantation interest is roughly estimated at nine millions sterling of English money.—(*Nature*.)

—FROM many growers and judges at exhibitions we have heard that MELONS have this summer been singularly DESTITUTE OF FLAVOUR. We have tasted many fruits, and have been struck with their remarkably low quality. In a season so sunny we should have expected this fruit to have been unusually excellent. Is the general lack of flavour due to an insufficiency of moisture? or has the quality of the fruit been appropriated by the red spider, which in many districts has been unavoidably prevalent? Let the cause have been what it may, the fact remains, as so many have expressed it, that “Melons have not been good this year.”

—We are informed that the DECORATION of the magnificent conservatory which has been recently erected by His Majesty the King of the Belgians at Laeken has been entrusted to Mr. John Wills of the Royal Exotic Nurseries, South Kensington. This conservatory is quite different from the usual structures which are erected for the cultivation and display of plants. It is quite circular in form, is about 60 yards in diameter and 60 feet high, and has already cost, we believe, £80,000.

## ABOUT DOVER.

THE vicinity of Dover is the birthplace of English gardening. The Romans and Augustine landed there, and they both introduced horticulture. Gardens accompanied the erection of their villas and monasteries. Even the Roman strongholds had cultivated enclosures beneath their walls, and I could point out at Richborough Castle boundary mounds that might have been around such an enclosure. Of that Castle the ruins of three sides remain clothed with Ivy, but where bare the layers of Roman tiles are visible. None of the usual tenants

of a garden are now within that enclosure except Fennel, and this is in profusion.

That the Romans introduced gardening to Britain is certain. I have noticed the traces of the gardens, and if the museums of Kent and elsewhere are examined implements such as we still employ are to be found amongst the archaeological stores of the Roman period. If reference is made to the writings of Cato, Varro, and Columella confirmatory information may be thence gleaned; and it is recorded that Lucullus introduced the Cherry into Italy and in a few years into Britain. This must have been into Kent, and the county is still noted for this fruit.

Of the monastic establishments, illustrative of what their occupants effected for gardening, the nearest here is St. Rheadegund's Abbey, having the addition of Bradsole or Broad Pool, from the large mere in its vicinity. It was within little more than half a century surrounded by woods, but the woodman's axe has swept very many of them away, and no proprietor has planted for his posterity: the Irish gentleman's reason has prevailed, "Posterity never did anything for me." Of this Abbey and of the walls of its barn, paradise, and orchard there are considerable remains, and for the most part covered with Ivy. It is one of the places where the wild Columbine, *Aquilegia vulgaris*, is found.

Roses are grown in this vicinity more generally and in greater abundance than in most country districts. At the flower show here on the 29th of August were prizes for Roses in twenty-four and twelve distinct varieties, and the collections exhibited were good in number and quality. At that Show I was asked for a list of the flowers and plants adopted by various countries as their national emblems, but the list I could give was very limited—England's Rose, Scotland's Thistle, Wales' Leek, Ireland's Shamrock, and France's Lily were all that I could remember. Of family badges I quoted the white Rose of the Yorkists, the red Rose of the Lancastrians, and the Broom (*Planta-genista*) of the Pantagenets. Can some reader add to the number, and send them for publication? North America has not hitherto adopted a national flower, but in the following extract from one of the New York Journals one is suggested:—

"In our broad land, with its many climates, we cannot have a flower common to all parts. But there is one fair blossom twined in the affections of almost every American, and its fragrance, so delicately subtile, comes with the memory of it. It was the first gentle welcome the pilgrims received from an unknown climate, and—

'God be praised!' the pilgrims said,  
Who saw the blossoms peer  
Above the brown leaves dry and dead,  
'Behold our Mayflower here!'

"Then if we have no national flower, why cannot we all unite in so christening our loved Mayflower or trailing Arbutus? Whittier exalts it to that honour when he writes:

'O sacred flower of faith and hope!  
As sweetly now and then  
To bloom on many a birchen slope,  
In many a pine dark glen."

"The pilgrims came and blessed the granite shores of New England with their faith. They crossed that threshold to 'our country,' and over stony paths and bloody battle fields unfurled the flag which in its purity and beauty has waved for a hundred years. Now, in our days of ease, prosperity, and happiness,

'Be ours the love that overruns  
Its rocky strength with flowers,'

and let us plant in the shadow of every star-spangled banner the emblematic blossom, with its pale tints and lingering sweetness, and know it by its homely name—the Mayflower."

One of my first excursions here was to Walmer Castle. Its flower gardens are most brilliantly crowded. I say gardens, because the moat is decorated in a style distinct from that of the garden proper. The latter is most richly furnished, so that I can say without reservation that in no garden is there massed throughout such a variety of the brightest-coloured flowers. The centre walk has a ribbon border on each side composed of broad lines of *Cerastium*, blue *Lobelia*, scarlet *Geranium*, and *Bachelor's Buttons*—the white flowers of the latter detract from the gradation of colour, which would be more effective if the white was superseded by a dark-leaved *Coleus*. Having seen the Willow overshadowing Napoleon's tomb in St. Helena, I hoped to see its offspring which for many years grew here upon the lawn. I was disappointed, for Lady Granville has had it destroyed. Her ladyship has superior taste in flower gardening, but appears not to have a reverence for trees, for

not only has the historic Willow but many patriarchal Beeches have fallen by her order to render the garden views more attractive. The destruction of timber trees is a thoughtless and injurious act, and more suggestive of consequences than the waste of coals. If Sweden and Norway do not plant as well as fell, their Pine forests must in time cease from yielding the hundreds of thousands of deals which I see daily unloading here. Why are they called "deals?" Was it because Deal was the usual place of importation? They could not have imparted the name to the place, for Deal is a contraction of the Anglo-Saxon for "a low seashore place."

An American journal states that "in 1870 the amount of sawed lumber consumed in the United States was 12,755,543,000 feet, with at least 50 per cent. of its aggregate value of shingles, staves, and box material. If this consumption goes on in the same ratio, as it is reasonable to infer must be the case, it is somewhat startling to conjecture how the next generation is to be supplied. We are assured, however, that there are still left 225,000,000,000 feet in the ligneous regions, to which may be added some 25 billion feet in the non-ligneous districts, while we must also bear in mind that forests are constantly growing. Notwithstanding the enormous destruction of hard timber for furniture-making, there is still left a belt standing from Central Pennsylvania to near the Gulf of Mexico of one unbroken forest of furniture timber, besides the fields of Indiana and southern Illinois, south-eastern Missouri, and one-fourth of the State of Arkansas. There also remains in timber over 40 per cent. of all New England, over 50 of New York, Pennsylvania, and Ohio, from which but a moderate share of that adapted to furniture-making has as yet been cut. And even our north-western Pine fields are not without a goodly share of furniture timber interspersed. This, however, does not exonerate us from taking good care of our timber lands, and doing all in our power to help them to increase and multiply."

The Napoleon Willow is not the only vegetable notoriety I have missed, for my search has not been successful for the Samphire rendered notorious by Shakespere. Neither on the cliffs nor on the shore beneath them have I found a plant of the *Crithmum maritimum*, but nowhere have I seen a greater abundance of the parent of all our Cabbageworts, the *Brassica oleracea*.

In driving to Waldershare, another notoriety of the vicinity, the road leading to Archer's Court is passed. The house is of respectable appearance, built of brick, but of no greater age than that of the Stuarts. It has, however, a history, part of which is that the manor tenure is that the tenant shall hold the king's head when he is seasick. This must have been arranged at the time when the king's only sea voyage was from Dover to Calais. Waldershare Park is the seat of the Earl of Guildford, and during the American War, Lord North often resorted hither and sought to recover equanimity after enduring the lashings of "Junius." The house is a fine old brick mansion, and the park is studded more thickly with noble Beech, Sweet Chestnut, and Oak trees than any other I can call to mind. I should have liked to have seen the gardens, but the head gardener, Mr. Merryfield, was absent. The mansion, from a design by Inigo Jones, was built in 1700, whilst the estate belonged to the Furnese family.—G.

## ERYNGIUM MARITIMUM.

At first sight the Sea Holly is to look at one of the most curious as well as one of the most interesting plants in cultivation. No plant, native or otherwise, calls forth so much wonder as the Thistle-like *Eryngium maritimum*, which is found wild in many places of our sea-girt isle. It, as well as all the family, are adapted for the decoration of ruinous places. The plants like a rocky or sandy medium for their development. They are not over-particular as to soil or situation. They thrive in partial shade or full exposure to the sun. They may be raised from seed or be increased by division, which is best done in spring when growth has commenced. When once established they continue healthy for a long time. The *Eryngiums* are grand objects for large borders. As we are now moving in the direction of hardy herbaceous plants, perhaps the subjects in hand may receive a share of attention that has hitherto been denied them. A group of them in the centre of a large bed is very attractive. All the family are of varied shades of blue. I am inclined to think that *Eryngium maritimum* is one of the most attractive of the race, having a silvery white appearance, affording a fine contrast to its beau-

tiful blue flowers. Some of the species are said to possess medicinal properties, and are of service in case of fevers. The kinds most commonly met with in cultivation are *E. alpinum*, *E. Bourgati*, and *E. amethystina*. There are others of this interesting family which ought to be brought into general cul-

Fig 27.—*Eryngium maritimum*.

tivation, and which could not fail to give satisfaction to the cultivator of them.—N.

### WORSLEY HALL.

THIS princely residence of the Earl of Ellesmere is about six miles from Manchester and one and a half from Worsley station. Worsley and its neighbourhood are celebrated for engineering difficulties that have been overcome in days gone by. From the terrace walk in front of the mansion you can see the railway trains rushing over the Chat Moss, a "Slough of Despond" that almost baffled the skill and patience of George Stephenson to lay his railway over it when he was engaged in constructing the first line from Manchester to Liverpool. Worsley itself is equally celebrated for the engineering skill displayed by Messrs. James Brindley, John Gilbert, and the Duke of Bridgewater, who in the year 1754 gave himself up to a life of unremitting work; and the purpose to which he devoted his life and his fortune was the development of the mineral wealth of the estate. Mr. Brindley supplied the brain power and the Duke found the money; the engineer being paid the small sum of 2s. 6d. per day for his wages. Other trans-

actions took place between the Duke and Mr. Brindley. The following modest bill for work and expenses has been copied from a photographic copy of the original. It is worthy of notice as showing the frugality of the man, and as affording a striking contrast with the "professional" charges of the present day.

Expenses for His Grace the Duke of Bridgewater to pay for traveling charges by James Brindley:—

	£	s.	d.
18 Novem., 1761. 18 No. Mesuring a Cross from Dunham to Warbuton, Mosely, and Thailwal. Dunham for 2 dinners, 1s. 8d., for the man 1s.; at Thailwal 1s. 2d.		0	7 4
All night Worington, 3s. 11d.			
19 Novem. Set out from Chester for London, and returned back. Going to London, and at London, then back to Worsley, charges Horses and myself	4	8	0
9 December, coming back from Hamston; charges at Wilderspool all night		0	8 0
At Worington, to meet Mr. Ashley, dining		0	4 2
10 do., Chained the Turnpike Rode, 2s. 6d., and again on ye 12 ye Rode, 3s. 6d.		0	6 0
21 Decem., To inspect ye flux and reflux at Hamston, 2 days charges		0	6 6
	£6	00	0

26 Decr., 1761, Recd. the contents of the above bill by the hand of John Gilbert, Esq. JAMES BRINDLEY.

Brindley's great work was the underground canals, the opening to which the visitor passes on the way to the Hall from the railway station, and will not fail to notice the peculiar-looking boats or barges floating in the basin. Through this tunnel the mineral wealth of the estate is carried in these deep narrow boats. The canals or tunnels extend to a length of forty miles. The boats are propelled by means of staples fixed in the roof, and three men can work thirty-two boats chained together and extending over a quarter of a mile. The Duke also made a canal from Manchester to Runcorn in one direction, and to Bedford Leigh in another, which the railways have not yet done away with. All the works of the late Duke are still in active operation, and are carried on by the Bridge-water trust. In "the yard there are three hundred persons employed, and about £60,000 worth of timber is annually brought to the yard to be used in the manufacture and repair of boats and barges and colliery appliances. In the yard is a square tower of tasteful construction, which contains a clock made by direction of the Duke. On one occasion he found one of the workmen late, and on inquiring the cause the man said he did not hear the clock, as it struck only once. This was speedily altered, and the clock was made to strike thirteen."

At that time the house built by the Duke was a plain red-brick erection, not a flower nor ornament of any kind was to be seen. Only the directly useful was tolerated.

The eccentric Duke selected as his heir Lord Francis Leveson Gower, who was but three years of age at his death, and it was not until 1833 that he took possession of the estate. He changed his surname, and was better known as Lord Francis Egerton, and ultimately as the first Earl of Ellesmere. His lordship, in conjunction with his amiable lady, sought at once to improve the moral and spiritual condition of their dependants. Schools were erected and maintained in Worsley and Walkden Moor, and ultimately churches were erected in their vicinity. One of them faces the principal entrance to the grounds. It is a fine building with a magnificent spire, and is worthy of its noble founder.

The kitchen garden is reached from this point by following round the outer wall and entering, as I was told, at the fourth gate. I was fortunate to find Mr. Upjohn at home. His cottage has been built on the margin of the Chat Moss, and part of the garden walls have been built on that insecure foundation, and even the mass of solid concrete underneath them has failed to keep them all in an upright position, the west wall leaning heavily outward. Everything about these gardens is of the most substantial character. The residence of the head gardener is both comfortable in appearance and elegant in design, and is also beautiful for situation. The kitchen gardens are about ten acres in extent. The ground is well and judiciously cropped, the Chat Moss soil appearing to answer for most vegetable crops. The walks are very wide, that round the outer walls being 14 feet, and it is very convenient for carting manure, as it admits of its being brought close to the gates.

The crops outside the walls are very good, vegetables of all sorts being in excellent order. I find that the Potatoes have not started to make a second growth, as they are doing almost everywhere in the neighbourhood of London, the haulm at

Worsley being very even in length, a sure sign of a good crop, Gloucestershire Kidney and Mona's Pride are the sorts most esteemed. Next we come to some fine rows and beds of Celery, and here again the appearance of the plants shows that care has been exercised in the selection of the stocks; Major Clark's Red and Incomparable White are the principal varieties. In this dry corner of Essex it has been a great difficulty to obtain Peas; the haulm has not been nearly so long as usual, but in the deep Chat Moss soil Peas have grown amazingly, and were at the hottest period of the year of that deep green colour which is a sure sign of robust health. I rather fancy that, notwithstanding the soil, skilful culture has something to do with the results. There was plenty of room between the rows, and the rows had been drawn in trenches about 3 inches deep and a foot wide. A large portion of the rain that falls runs into the trenches, and they are convenient when artificial watering is resorted to. Williams' Early Prolific Dwarf Kidney Bean is considered to be

the best variety for forcing and early crops. There is also a fine breadth of Beet; the best seemed to be Dell's Crimson, a fine highly-coloured sort, the foliage of a deep reddish purple shade, the roots medium-sized, of a deep red colour and excellent flavour. This variety has many synonyms, amongst others Osborn's Red, Improved Black-leaved, Perfection of Beets, Dwarf Waterloo, &c. Altogether this part of the garden is in excellent order—the ground free from weeds, and the crops in superior condition.

As we enter the walled garden at the side furthest from the gardener's house the first object that arrests attention is the "Trentham Peach cases" for walls. This is an elaborate structure, with high front upright sashes and a span-roof. It requires only a glance to see that this is not nearly so well adapted for ripening fruit on trees trained to the wall as a light lean-to glass framework that could have been put up neatly and substantially for a third of the expense; indeed,

Fig. 28.—WORSLEY HALL.

Mr. Upjohn has found that the fruit does not ripen well on the wall trees, and he has removed some of the trees from their position against the wall and planted them about a foot or more from the front wall plate, and trained them to a trellis near the glass. The best Peaches (and of them there are fine examples) are Early Alfred, Royal George, Red Magdalen, Stirling Castle, and Barrington.

We next inspect the vineries, a range of wide roomy structures in four divisions, comprising early and late houses. Mr. Upjohn was anxious to test the new Grape Vines that have been sent out recently. He has tried nearly all of them, and has some of the more recent now on trial, but none of them are likely to shake his faith in the Black Hamburgh and Muscat of Alexandria. These two sorts will be grown when most of the recent varieties are forgotten; not that many of the new varieties are unworthy of culture, nearly all of them have some quality or another that recommends their culture to connoisseurs; but when a gardener has to keep up a continuous supply of Grapes for a large family he will grow those sorts that can be depended upon at all times and under any circumstances. The craving for something new in these recent times has had much to do with flooding the country with novelties that please for a little, but will not stand the test of time. The earliest house is mostly planted with Black Hamburgh and a few Snow's Muscat, with one Vine only of Madresfield

Court Muscat. The next house in the range is a late one, and contains some vigorous Vines, on which were hanging excellent examples of Black Hamburgh Grapes; Gros Colman, Alicante and Lady Downe's are also grown. Passing on to the next division we have Buckland Sweetwater and White Lady Downe's. This variety has not come into extensive cultivation, but Mr. Upjohn thinks highly of it as a late-keeping Grape. It is quite as good in flavour as Lady Downe's, and keeps equally well, this last quality being its best recommendation. Venn's Black Muscat has also been planted, and Gros Colman is growing strongly, carrying large bunches and berries, but they do not colour well, nor are they of good flavour. In the fourth house Muscat of Alexandria is the principal sort, and Charlesworth Tokay, which is only a form of Muscat of Alexandria. Duchess of Buccleuch—a rod of this sort should be grown wherever there is a large range of vineries. It is a most exquisitely flavoured variety, but it is, perhaps, surpassed by Pearson's Dr. Hogg. There are also canes of Duke of Buccleuch and Waltham Cross. The first-named sort had a number of bunches; the berries were very large, measuring  $4\frac{1}{2}$  inches round the shortest way, but the berries are very nearly round, differing in this respect from Golden Champion, the berries of which are more elongated. The berries have set very well on the Waltham Cross, and have formed large compact bunches. While the Vines were in flower the tempera-

ture was kept at 65° at night. From here we pass into the Peach house, the most conspicuous object being a fine tree of the Victoria Nectarine. Here, as everywhere, this fine late sort is much valued.

We are next attracted by large ranges of pits. A few of them are span-roofed, but the greater number are lean-to's, constructed for bedding plants, of which about sixty thousand are required. A span-roofed house 50 feet by 12 feet wide has been planted with Melons. There are beds on each side of the centre path, and it is a fine sight to see the fruit hanging from trellises on each side. Unfortunately a disease has taken the plants in the form of canker. It is not unfrequent to see Melons die off with canker at the base of the stem, but here it has spread over the whole plant, and bids fair to spoil as fine a crop of Melons as I ever saw. One plant that had been planted in the Chat Moss peat was later than the others, but quite healthy and free from canker.

Pines are grown in lean-to houses or pits that have been heated on the Polmaise system; this, of course, has been altered to the usual hot-water pipes, and it is astonishing how good Pines can be manufactured in such old-fashioned structures. There were some good Queens and a few Jamaicas and Smooth-leaved Cayennes coming on for winter use.

Figs are also grown in this range, and fairly good fruit is produced; but it is very trying for a gardener who has old-fashioned houses like these to manage to compete with those who have everything done according to the present system of building and heating. My remarks have extended far enough for the present, and a few notes made in taking a walk through the grounds must be kept for another occasion.—J. DOUGLAS.

## ORNAMENTAL AND USEFUL TREE-PLANTING.

No. 4.

Of trees adapted for city growth and patient of town smoke, one or two, and those among the best, have been enumerated in the foregoing groups. The Western Plane is familiar to the eye of the most thorough Londoner in most of the squares and in the very heart of the City. It retains its health and grace whether in leaf or leafless. The foliage of the Horse Chestnut, too, takes little hurt from smoke or drought, and as the tree is content with hard soil and scanty root room, it should be welcome in towns, even if it comes short of its finest growth, for its racemes of blossom, which might be varied by those of the rose and yellow-flowered species. The Lombardy Poplar which keeps its health and gloss despite of drought and dust, deserves to be used for avenues and boulevards in the broader streets, and the same may be said of the *Quercus fastigiata*, which resembles it. The weeping large-leaved Elm (*U. montana pendula*) has approved its qualifications for a London tree, adapted for the parks and gardens as well as smaller squares. Mr. William Robinson, to whose authority on such a question we attach great importance, refers us to the specimen of this tree on the lawn of the Botanic Gardens. In general, Elms and Limes have no business amidst the smoke and dust. To judge by the same writer's experience of the *Robinia inermis*, a round-headed variety of the Locust Tree, in the cities of north Italy, it ought to do well in our London parks and gardens, where its umbelliferous top, deep verdure, and grateful shade, could not fail to create a favour for it. A tapering variety (*Robinia pseudacacia stricta*) is in habit very like the Lombardy Poplar, and might with advantage find its way into our town gardens, which it would enliven by its racemes of white and fragrant blossom. For this merit, in addition to their ample and broad foliage, we suppose that the *Ailanthus*, *Paulownia*, and the *Catalpa syriaca* would be additions to our City parks and squares. The first, if least conspicuous in flower, yields to none in fresh and healthy dust and drought-proof foliage. The second affords an abundant shade from a mass of leaves larger than those of any hardy tree, while its fragrant violet flowers in large terminal panicles are as showy as the Foxglove, which they somewhat resemble. Tender in the north, they will thrive in the climate of London, and are very successful in the gardens of Paris. The *Catalpa* too, not unlike the *Paulownia* in size of leaf and beauty of flowers, is perfectly hardy about London. Its blossom is white with yellow and purple spots. There is a fine-grown *Catalpa* at Muswell Hill. The weeping grafted variety of the *Sophora japonica* is another flowering tree of graceful habit, the pretty foliage of which has no objection to the heat and drought of towns. Into the urban parks and gardens Mr. Robinson would freely introduce the free-growing *Rosacæ*, Hawthorns,

Pears, and Almonds, for their diverse spring bouquets, and which is more worth consideration among trees, the *Liriodendron tulipifera*, a hardy timber tree with large, light-green saddle-shaped foliage, and when it has attained a fair size, a display of cream-coloured Tulip-shaped flowers. It was an early introduction from North America, and has been known to reach 120 feet. Before quitting this part of our subject, and whilst remembering the difficult problem of unsightly stems of trees in a dying or dead state to be met with in the parks, we may borrow a suggestion from the "Heatherside Manual" to plant at their feet such twining shrubs as the *Wistaria*, and *Aristolochia*, and *Akebia*, by which means many an indifferent trunk or group of trees might become a network of mixed foliage.

But though deciduous trees are the backbone of our native timber, where would be the setting of our picture of reds and yellows, where the supplement and finish to our gardens, lawns, and even parks, but for such extraneous races as Pines and Firs, Cypresses and Junipers? Of these the first and second constitute a threefold clan, amongst the members of which none is more worthy of commemoration than the Scots Pine, the sole indigenous species. Its nature is thoroughly hardy; it thrives, as indeed do many others of its race, on the poorest soil and the scantiest, its roots penetrating through débris and fissures of rock, and its growth assisted most by free air and a sandy gravel. Some of the Pines no doubt require more shelter and a lower altitude than others, but the soil they appreciate most is one assimilated to that of their native habitats, where at least the accidental top-dressings are accumulations of débris and vegetable matter, and not rich manure such as cultivation and solicitude might suggest for them. It is probable that nothing improves the Conifers of our gardens and home-precincts so much as an occasional cartload of road scrapings. What the Scots Pine is in its native forests Mr. Grigor tells us in his description of Glenmore Forest, one of the largest trees in which was cut up and a deal from its centre presented to the Duke of Gordon by the ship-builder who bought it. The annual layers of wood, according to Grigor's "Arboriculture," from its centre to each side number 235, indicating that number of years. The surface of this forest is sandy peat, its subsoil a rich brown clay. The produce of it built forty-seven sail of ships for the Royal Navy and the East India Company. But amongst southerners it is no mean tree in point of beauty or usefulness. Note its fantastic shapes, its dark red stem, its warm bluish-green foliage, as in winter or summer it stands out into the sky in contrast to the deciduous trees around it. No tree for the picturesque can beat a pair of Scotch Firs, or even a single one. Wordsworth, Mr. Grigor tells us, preferred it to the Oak in winter, in moonlight, and at evening. Next to it in hardihood is the Austrian Pine introduced by Mr. Lawson in 1835 from the Styrian forests, but now thoroughly naturalised and appreciated in Great Britain. It is a quick grower, of dark green glossy foliage, and strong stiff leaves with a pricked point. It makes an excellent shelter, and bids fair to make a noble and ornamental tree, as in its own country it reaches 150 feet. A good contrast to its dark foliage might be found in the clear transparent green of the *P. pyrenaica*, which was brought about the same date from the highest mountain range betwixt France and Spain, and is of noble aspect, odorous bark, and quick growth. There is one at Dropmore 75 feet high, and it is said to grow above 80 feet. From the "Forester," however, we gather that it is more for ornament than use, and that though used for the decks of Spanish ships, it is inferior to many of our naturalised Pines as timber. The Corsican Pine, *P. Laricio*, is of far greater value as one of the most sound and rapid-growing of Conifers, of great hardihood, and a capacity of reaching 120 feet. It has attained to upwards of 70 feet at Dropmore. Nor is it less ornamental than useful, having a distinct pyramidal habit from the horizontal spread of its whorls of branches, and the loose wavy spread of its dark bright-green leaves. The Calabrian Pine is not unlike it, only with longer and more slender foliage. The Cluster Pine (*Pinus Pinaster*), introduced by Gerard from the south of Europe in 1596, is also a rather handsome tree, rugged and massive when seen alone, as at Fulham Palace, 80 feet in height and 12 in girth. But its prime use is with the Norway Maple, to screen plantations on the seacoast, in which respect it has assisted Norfolk to emulate the coast of Gascony in the recovery of sandy tracts. As timber it is of slight account; and herein, as in its deep green foliage and depth of root, it resembles the Stone Pine (*P. Pinea*), though differing from it in being far

less bushy and stunted, as well as in having starlike and not round cones. The latter came from Italy earlier in the same century, and its best use is for a dense bush to hide objects just behind it.

The above-mentioned Pines, with two or three interesting dwarfs, have their leaves in pairs. Of those which have them in threes the most considerable are *P. macrocarpa*, *P. Benthamiana*, and *P. insignis*. The first came to us about forty years ago from California, the third in the same year, and the second about fourteen years later from the same country. Already the wavy habit of the glaucous grey foliage on branches horizontally set and distant from each other, the violet bark of the young shoots, and the length and breadth (12 inches by 6) of the dark yellow cones of *P. macrocarpa*, make it a striking contrast to the dark-hued Conifers, and inspire hopes of a majestic tree if in its younger stages its tops do not suffer from the action of the sun after a frost. In its home it attains 100 feet, a height which is doubled, however, by *P. Benthamiana*, a hale giant, with branches irregularly spread, clustering cones, and dark green leaves, resembling those of the North American *P. ponderosa*, only longer and darker. It has the advantage over the latter that it makes deeper roots; and it is of rapid growth if defended when young from the ravages of insects. From its mountain home in the Sacramento country we should augur its hardihood in Great Britain; though there might be more questions as to *P. insignis*, which is probably from lower altitudes, and certainly needs shelter from frosts, although it likes a situation fairly high and dry. The grassy green of its foliage makes it a lovely contrast to the darker Conifers, as well as to most deciduous trees. Indeed it is a Pine worth care and watching, one that no lawn or park should be without. That it may weather our frosts and survive our winters is proved by its attainment of the height of 70 feet, with a girth of 8 feet 7 inches, in that nursery of choice Conifers, Dropmore.

Of Pines with five leaves none surpasses the Himalayan *P. excelsa*, naturalised in this country for some fifty years. An open, spreading-branched, conical tree, it has a pale bark, pendulous habit, and long slender glaucous green leaves. It likes air and light, with moderate shelter, and bears some resemblance, though of more elegant habit and rapid growth, to the Weymouth Pine (*P. Strobus*). In its own country it is called the Weeping Pine, and found with the *P. longifolia*, or Cheel tree, and the Pinus Kutrow. *P. excelsa* reaches 120 feet in its own country, and *P. Strobus* 130 in its North American home. Of the timber of the former we know no more than that it is white, compact, and resinous. The latter often passes for red deal from America, though not really equal to it in quality.

The oldest type of Spruce in this country is the Norway Spruce (*Abies excelsa*), which was introduced as early as 1548. Unlike the Scots Pine, to which of our home-grown timber it comes next for plants and scantlings, it is of pyramidal habit, and feathers horizontally from top to bottom. Its deep green foliage is rich and dense. Owing to its rapid growth and encroaching roots it is not so good a nurse as it was expected to be, but it will do justice to ground of its own in a sheltered hollow free from wet subsoil, and should be planted in a group or singly. In such situations it may reach the height (130 feet, and 16 feet in girth) of the Studley tree, said to have been planted by Eugene Aram, or the Blair Athol Spruces, some of which are 110 feet high. The Black Spruce (*A. nigra*) with blackish bark, light spiral form, and dark green foliage, differs from the excelsa in its more pointed habit. But most familiar to us after the common Spruce is the Canadian or Hemlock Spruce, a contrast to it in its vivid light green foliage, with a silver striped underlining. Slow to start into growth, and particular as to soil, it is a little disappointing at first; but towards thirty or forty years of age it assumes a graceful pendulous habit, which, however, changes to horizontal, and becomes more Cedar-like as the tree grows older. We do not hear of it as a timber tree; but few Conifers are so noticeable for elasticity or look so well when bearing, as it does without collapse, a heavy burden of snow. There are good samples of this *Abies* at Studley Royal, Elvaston, and elsewhere; but it has not yet reached in Great Britain its Canadian height of 110 feet. *A. Albertiana* from Oregon (1858) of which our largest English sample is about 20 feet high, is said to be likely to eclipse it in grace, growth, and timber. At home it reaches 140 feet. The fault of the White Spruce, a slow grower of silvery aspect, and of the *Abies Morinda*, a Himalayan Spruce of drooping habit and great promise, is their impatience of

transplanting; but this fault cannot be attributed to the *Abies Douglasii*, a king among Firs in respect of vigour, habit, and dense dark foliage. The young shoots are of a tender light green, the mature leaves bright green above, pale and glaucous below. Introduced from North America half a century ago, it has reached upwards of 100 feet at Dropmore, and 70 at Hopetoun House; and feathered to the ground with foliage of cheerful bright green above, and a glaucous underleaf imperfectly two-rowed, it is really noble to look upon. Few Conifers are easier to acclimatise, as the seeds ripen readily, and with moderate shelter the young plants are not fastidious as to soil. The Dropmore specimen was raised from seed in 1828. The Californian *A. Menziesii* is not unlike it in character and nobility of aspect, besides being nearly as rapid a grower and very hardy. It might be worth planting for forest purposes, though as a single tree it is against it that it is semi-deciduous, and that its branches are left bare during part of the spring. We have yet to mention *Abies* or *Picea nobilis*, perhaps the most majestic Fir of all, a Californian species introduced in 1831 by Douglas, of pyramidal appearance, deep glaucous hue, and an incurved habit of foliage which allows a view of its glaucous underleaf. The bark of the stem is cinnamon-hued, its branches and cones being of a purplish tinge. Like *A. Douglasii* it is undeniably hardy and adapted to cool-bottomed soils in moderate shelter. In Mongredien's "Trees and Shrubs" there is an engraving of a fine specimen at Wimbledon; and another at Dropmore is from 50 to 60 feet high. Others in Scotland are of equal height and proportionate girth; but we learn that one such was uprooted by the high winds of last October.—(*Quarterly Review*.)

## FLOWER GARDENING.

"EVERY dog has its day," and so has every fashion. Now that a reaction has evidently set in with considerable vigour in favour of hardy herbaceous flowering plants, some seem to think that what has been nicknamed "bedding-out" has nearly had its day, and that it must be cast aside as a fawdry vulgar delusion, if not something worse. Well, our strength does sometimes grow out of our weaknesses; and like the stag which admired its elegant head of horns and was ashamed of its feet, till the hunters appeared on the scene, when what appeared its shame proved its best friend, so what in gardens has been most admired may turn out of least use to us. There is, however, a use and a place for everything in the way of flowers as well as there is for horns and feet. There cannot be a doubt that our grand old herbaceous border plants have been far too much neglected for a long time, and it is matter for rejoicing that the tide has set-in in their favour.

While we agree with every word that some writers have said of the folly shown in so much neglecting hardy plants, we have no sympathy with their sweeping condemnation of the modern system of parterre flower gardening. It is not only the most effective and appropriate style of flower gardening for certain positions, but it has, beyond all doubt, done more than any other system to popularise and foster the love of flowers among the masses. And we do not believe, nor do we desire, that we are near the end of its reign yet. The great charm of the one is that it is diverse from the other. The two together make a complete whole in gardening; and the discussion about the superiority of the one over the other is, to say the least, unprofitable. The one may be regarded as the brain, and the other the heart of flower gardening.

The error in this matter has been in allowing one phalanx of flowers to elbow every other out of many gardens. This has resulted neither from good taste nor economy. Great errors of judgment have also been manifested in trying to adapt the massing of tender plants which do not bloom effectively in many localities to every garden. There are some localities in the British Isles where this style of gardening has proved just so much labour lost, and where it should never have been attempted except on a small scale, especially as it is just in such localities that hardy herbaceous and alpine plants are more satisfactory. In moist sunless districts the grouping of tender flowering plants outdoors never could be more than a comparative failure, while it is just in these localities that most herbaceous and alpine plants grow the best and continue to bloom vigorously for the longest time possible. But then, herbaceous plants in some other localities, where the soil is sandy, dry, and poor, and the rainfall very little, bloom but for a short time; and let the autumn, as it frequently does, prove one of drought, and the herbaceous-border gardening is one of

the most dejected spectacles that can possibly be imagined. Here then is the locality that suits the tender system, and where it should preponderate and be developed to as high a pitch as it is possible.

¶ We are not going to balance the tastes that come into play in making a hobby of any system of gardening; what we want to show is the futility of trying to gain an end and gratify a taste with all the elements of nature against you, and the stupidity that has been practised in trying to get a kitty wren to develop canary's feathers. Then, again, there is the season of the year at which a floral display is required. This should have something to do with the decision of those who love flowers. Taking the great gardens of this country, as a rule nine-tenths of their proprietors are absent from their country seats when herbaceous plants are in their glory, and arrive at their seats to see only the fag (and that the least interesting) end of them. On the other hand, there are numbers of proprietors of our lesser villa gardens, who, as a rule, leave their places for a month or two, just when the tender system is coming into bloom, and come back to see it either washed out with wet or cut down with frost. In the case of the latter, their error lies in not going in for the hardy system, which they could enjoy all spring and early part of summer. The adaptation of systems, in most cases, is what is called for, not their extinction, and in many cases the combination of the two yields by far the greatest amount of pleasure.

Besides, before we can substitute any one system for another, an entire revolution must be wrought in the plans and disposition of our garden grounds. In many cases this, in our opinion, would be desirable, apart from any floral effect whatever, for in many places the entire repose and natural beauties of the grounds have been so tortured with square and compass that there is not a line of beauty or a refuge for repose to the eye left. This is one great abuse to which our geometrical flower gardens, for colour displays alone, have led. Every piece of greensward has been tortured with the most nonsensical whirlinggigams that an expert hand at the compass could devise. It is not that such designs should not be in their best forms, but the evil has been that they are wrongly placed. They stare at you everywhere, and hard lines of Box and grass, and glaring gravels and broken spars and stones, have taken the place of "lines of beauty" and graceful vegetation.

We are afraid that even yet comparatively few have sufficiently examined and observed our hardy border flowers to discover their extreme beauty. If a plant comes from "some place far abroad," sells for ten or fifteen guineas, and requires a temperature enough to stifle a human being, it is a world's wonder. Let the observer take it out to the herbaceous border and compare it with that exquisitely formed, pencilled, and shaded hardy Iris that will thrive by a ditch side or in cold ungenial soil, and we will answer for it the Iris does not lose by comparison. Take that splendid spike of *Calanthe*, or anything you please, and lay it side by side with that towering spike of wondrously coloured and formed *Delphinium*, and see which loses by the contrast. Go into the grandest modern parterre garden in Europe, and make up the most graceful bouquet that an acre under tender plants can supply, and then go with the same skill and discrimination into your herbaceous ground and make up a bunch or vase of flowers from it, and if the latter does not make the former pale, both for exquisite delicacy of colouring and beautiful graceful forms, it will be surprising. Go again in search of interesting objects into the one garden and then into the other, you will find food for observation and study, as far as variety of form, colour, and character are concerned, that will be inexhaustible, and fresh and new every day for long months in the year, in the one as compared to the other.

We can look out from where we are sitting on a mixed garden, where there are Roses, Carnations, Phloxes, *Delphiniums*, *Pæonies*, and hundreds of varieties of hardy herbaceous plants, annuals, &c., that, so far as we are concerned, we would not exchange for any amount of tender parterre gardening; but, for all that, we do not condemn it in its proper place. Let them both live. The one is a splendid relief to the other. All who want a never-failing source of interest and a richness of cut flowers should grow selections of hardy herbaceous plants; and all who have gardens, large or small, in damp localities, where late and early frosts prevail, should by all means let the hardy style of gardening prevail. It yields by far the greatest amount of beauty and satisfaction. In such a climate the *Phlox* and the *Delphinium* and the whole varied train of hardy beauties luxuriate the most; and there are many, we fear, who

have but little idea of the splendour of such plants when well cultivated instead of being merely kept in existence. Those who think herbaceous plants do satisfactorily without high cultivation labour under a very great mistake. Indeed, in soils that are naturally poor, and where the climate is dry, their blooming is a mere flash in the pan, and they are mostly withered and gone by midsummer, unless, under such circumstances, the very highest culture is brought to bear on them. Deep trenching and heavy manuring, watering and mulching, are the price that must be paid for satisfactory results in this style of gardening, and the most shady (without being under trees) situations should be selected for the hardy garden, and selections of plants to suit different soils and climates is also desirable.—(*The Gardener*.)

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

It is a good plan to look carefully over the wall trees early this month, and to see that no shoots are hanging loose from the walls. The whole garden looks untidy if the wall trees are not kept in good order. Peaches and Nectarines are either ripe or approaching to that stage, it is therefore desirable that no water should be applied to the trees by the syringe or garden engine. All insect pests ought to have been destroyed long before this time. See that the leaves are not allowed to shade the fruit from the sun: it is better to cut half of a leaf off, if that will be sufficient to expose the fruit, than to wrench it off carelessly. Those who have paid attention to Peaches will have noticed that if a leaf is allowed to overshadow any of the fruit until it is ripe, the mark of the leaf will be noticed on the fruit. Earwigs have been very destructive to Nectarines; the woolly coating of the Peach seems to be distasteful to them, but it is possible that they might attack the Peach if no other fruit could be had. The best way to capture and destroy them is to place Bean stalks cut into 6-inch lengths near where they feed, they retire into them by day and may easily be blown out and destroyed.

Vines on walls out of doors ought not to be neglected at this season; if there is not a large crop of fruit on them, much lateral growth is made, which should be pinched back before it is necessary to use the knife. It is not well to allow the Vines to make considerable growth and then to cut it off in armfuls or barrow-loads. The fruit of Royal Muscadine or Sweetwater may be exposed to the sun, but Black Cluster or any other similar variety colours better if the bunches are partially shaded by the leaves. When the fruit of black Grapes is too much exposed to the sun it is more liable to scald than the white sorts. We have seen many bunches of Black Hamburgh Grapes out of doors this year quite destroyed in that way. White Sweetwaters on the same wall have not been injured. It is interesting to note the effects that the sun has upon different varieties of Grapes. It seems that white varieties do not suffer injury so much as black, and none of the black varieties colour well if fully exposed to the sun. The tendency of Lady Downe's to scald is well known, but its white counterpart does not scald under the same treatment. All the leading growths should be nailed to the wall, and the main leaves should be well exposed to the sun. If wasps and flies make a raid on the ripening fruit they will utterly destroy it if they are not prevented; about the best plan is to place the bunches in gauze bags. The fruit must be occasionally examined, as it is more liable to decay in the bags than when it is open to the weather.

There is a fair crop in some districts of Pears and Plums on the walls. The latter are also very frequently a prey to wasps and bluebottle flies, especially such sorts as Green Gage, Jefferson, and Coe's Golden Drop. The only effectual way to save the fruit is to cover some of the finer specimens with gauze. Pears should be gathered at different times to keep up a succession as long as possible. Williams's Bon Chrétien is a very fine Pear that has become well established in popular favour, but it has a formidable rival in *Souvenir du Congrès*, evidently a seedling from it. The new variety seems to keep rather better, is larger in size, and has not so much of the musky aroma that is found in Williams's. It is also a very free-bearing variety. Another new Pear, Madame Treve, succeeds the above, and does equally well as a wall or orchard-house tree, and is a very free bearer. Mr. Rivers recommended this variety as being very high-coloured on the exposed side, but it has not been so with us, it is not even so highly coloured as *Louise Bonne* of Jersey. It is best to gather a portion of all these early Pears before they are ripe, and make another gathering in a week, and yet another about a week later. If it is intended to plant any fruit trees during the ensuing winter the ground ought to be prepared now. It ought to be trenched up to a good depth, and if poor some decayed manure ought to be added.

Our Strawberry plants have been planted long ago, and are

now strong plants. Those who intend to plant and have not commenced should do so without any delay, so that the young runners may become established before the winter. All the young runners should now be cut away from the old plants. Some rich manure may then be applied to the surface and be forked-in, taking care not to injure the roots.

#### VINERIES.

We shall do nothing more to the early vineries until the time comes to prune the Vines. All the ventilators and doors are open night and day; and the weather so far is cool with little sun by day. The leaves have been thoroughly washed with the garden engine to destroy red spider. The Grapes are not yet ripe in either of the late vineries, and if cold weather continues it will be necessary to apply artificial heat to ripen them off. Except when the vineries are being fumigated it is better to have the ventilators open a little both at front and back. Even in cold weather a small chink of air causes a circulation.

Some of our friends have told us that red spider seldom attacks their Vines; but we generally find they are those who have both climate and soil in their favour. A moist climate and good deep clayey soil is not favourable to the existence of red spider. We have it in both the late houses, and have tried the hot-shovel-and-sulphur method of destroying it. The method has been well tried, but so far we do not think it so effectual as our old method of heating the hot-water pipes to a high degree and painting them thickly. The advantage of painting the pipes seems to be that the suffocating atmosphere is kept up for a longer period—twelve hours at least; whereas by heating the shovels and filling the house with sulphur fumes to as great an extent as the Vines will bear, the spider is not kept in the deleterious atmosphere nearly so long. There are still many good gardeners who doubt the efficacy of sulphur fumes to destroy red spider. Our own experience tells us that they have not given it a fair trial.

Vines in pots for early forcing should be undergoing the period of rest. They ought not to be fully exposed to wind and rain after this, but should be pruned and placed under glass where there is free ventilation, and the soil ought to be watered occasionally to prevent it from drying too much.

#### PLANT STOVE AND ORCHID HOUSES.

There is great danger of stove plants being injured by too much shade in September. It is not yet time to remove the shading altogether, but it never ought to be used unless it is actually required, and that is at the hottest part of the day and during bright sunshine. There are some plants which would be injured if they were not shaded; others suffer if the shading is put over them. If possible *Stephanotis floribunda* ought to be fully exposed to the sun; if it is not it will not flower abundantly next season. The young growths ought not to be too closely trained together. *Clerodendron Balfourianum* is one of the easiest grown and most useful of stove climbers. It is also as easily propagated as a *Verbena*. Our plants are making very strong growth, and they are encouraged to do so by liberal supplies of water. By resting the plants at different periods a succession of flowers of *Gardenia florida* can be obtained. This useful plant will stand a greater degree of cold than many gardeners imagine. We have had plants go through the ordeal of 3° or 4° of frost and not be materially injured. They are very liable to be attacked by the mealy bug. Strong soapy water applied with a sponge, and keeping the plants in as low a temperature as they will bear, soon rids them of all insect pests. When growing the plants require to be freely syringed. Much pot room is unnecessary, as they grow and flower freely in pots that would be thought small for the size of the plants. See that all climbing plants are kept within bounds, and all flowering specimens near the glass, and to be kept free from all insect pests.

The same treatment is necessary with Orchids. A large proportion of them ought to be freely exposed to the sun after this time. *Cattleyas*, *Lælias*, *Dendrobiums*, and some of the Mexican species of *Odontoglossums* are all benefited by free exposure. *Phalenopsis grandiflora* and *P. amabilis* are injured if the sun acts upon the leaves as yet; nor do many of the *Acridas*, *Vandas*, and *Saccolabiums* bear much sun upon the foliage with impunity. The best plan is to place all plants that yet require shade at one end of the house, and those which it is not necessary to shade at the other end. All the *Calanthes* are making vigorous growth; *C. veratrifolia* showed by the thick succulent roots it was making close to the surface that now is the proper time to repot; this was done, using good yellow loam, with a little decayed stable manure and sharp sand. This species and *C. masuca grandiflora* are very useful for flowering during the early summer months, they last such a long time in beauty. We have had spikes of *C. veratrifolia* last for very nearly three months. Some few Orchids that are grown in the coolest houses like exposure to the sun after this time; amongst them may be named *Cattleya citrina*, *C. autumnalis*, *Lælia majalis*, and other Mexican species; but the alpine species from the high mountains of Peru and New Grenada still require shade, notably *Odontoglossums* of sorts, including *O. crispum*, *O. triumphans*,

*O. Andersonianum*, *O. gloriosum*, &c., also most of the *Masdevallias*. Where so many plants requiring diverse treatment are crowded into one house it is almost impossible to do all of them justice. *Odontoglossums* and *Masdevallias* require a good supply of water at the roots; *Cattleyas* and *Lælias* not so much.

#### FLOWER GARDEN.

The bedding plants were much checked by the drought, and we were later than usual in putting in the cuttings of Zonal *Pelargoniums*; this has now been done, placing the boxes on a sunny border out of doors. *Centaureas* have been put into a cold frame, and the lights are kept close until the cuttings strike root.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

William Bull, King's Road, Chelsea, London, S.W.—*Retail List of Bulbs and Tuberous-rooted Plants*.

Ireland & Thomson, 20A, Waterloo Place, Edinburgh.—*Descriptive Catalogue of Dutch and French Bulbous Roots, &c.*

William Rusey, Joyning's Nurseries, Waltham Cross, N.—*List of Roses, Ornamental Trees and Shrubs, Bulbs, &c.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.

GLASGOW. September 12th and 13th. Mr. F. Gibb, Doughall, 167, Canning Street, Sec.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY. September 18th.

KILMARNOCK. September 14th. Mr. M. Smith, 11, King Street, Sec.

IPSWICH. September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

LANCELOT BROWN (W. D.).—His portrait will appear in our columns in due course.

FLORAL DEVICE (J. C.).—It is a figure, such as a star or crown, formed of flowers.

WYCH ELM (A. J. H.).—It seems to have been so called because its wood was especially used for making chests, which were called *wyches*. The spelling of "wych" is a corruption.

BEDDING GERANIUMS (N. C.).—There is only one Geranium likely to surpass Indian Yellow of the same tint of colour, and that is *Jealousy*, which is more decidedly yellow, and is equally floriferous. *Vesuvius* is still one of the best scarlet bedders, and splendid in this colour is *Corsair*. Rev. T. F. Fenn is one of the best crimson bedders, Edward Sutton also being superior. Mrs. Turner and *Amaranth* (pink) make excellent beds. Madame Vaucher is still the best white variety for bedding purposes.

VINES OVER-LUXURIANT (*Somerset*).—Since seeing the plan we do not advise your cutting a trench by the side of the wall, at least the wall of the house; but you may well do so at the extremity of the border if the Vines are very gross. Remove the surface soil as previously advised, take out Vines Nos. 2 and 4, train a young shoot from the base of No. 1 horizontally until it reaches the next rafter, up which train it; from this rod you may if you choose take still another cane, and train it up in the place of No. 3, bending the latter to occupy the place of No. 4, which remove; you will then have three rods of Black Hamburgh and one of Foster's White Seedling, and will obtain more and better Grapes than by your present plan. Wrap the exposed stems with hay bands.

STOPPING CHRYSANTHEMUMS (F. B.).—Plants which have been stopped early in July will flower perfectly if they are properly cultivated—i.e., if they receive no checks by drought, mildew, or insects.

PRESERVING BEDDING PLANTS (*An Old Friend*).—Your Tricolor Geraniums should be potted, and if a little soil adheres to the roots all the better, although the pots used should be as small as possible consistent with holding the roots. The plants should not be cut down, but a portion of the large leaves should be removed, which will assist the shoots to harden. The plants may be cut down in spring if required, making their tops into cuttings, which strike freely at that time in gentle heat. Zonals may be cut down in the autumn if the old plants are required to be preserved in a dwarf state. You may take up the *Lobellias* and divide the plants, placing them in small tufts in pots and boxes, but only the plants which are making fresh growth from the base, the flowering parts being cut away. *Alternantheras* may be treated in much the same way, but require more heat than *Lobellias*. *Mesembryanthemums* are best preserved by striking the cuttings, which root freely at the present time in gritty soil. They should be placed in gentle heat. *Verbenas* do not succeed well when potted from the ground, hence the

advice which you have quoted. Cuttings selected from shoots which have not flowered strike readily and make good plants. It is not necessary to cut round the roots of Geraniums for some time before taking them up. An excellent selection of Geraniums may be found in the Journal for last week, on page 186.

**JUSTICIA UNHEALTHY (J. Mark).**—The leaf sent us is infested with the scale (*Coccus testudo*). It may be destroyed by a solution of soft soap, 4 ozs. to a gallon of water, with the addition of a wineglassful of spirits of turpentine, and applied to the parts infested with a brush or sponge; or the plant may be syringed with the solution, taking care to wet the under side of the leaves where the insects will be principally located. We prefer to apply the mixture with a brush and sponge, and afterwards syringe with water at a temperature of 120°. The turpentine should be mixed with the soap in a little boiling water, then add the remaining quantity of water, applying at a temperature not exceeding 120°.

**STORE-ROOM FOR APPLES AND PEARS (J. P., jun.).**—You could not have a better aspect than north-west—that is, failing a due north aspect. A south-west aspect would not suit, as it would not afford such a cool and equable temperature as a north-west one. You will require light to facilitate storing and for examining the fruit from time to time. We should have a light in the roof sufficiently large as to light the room thoroughly, and that should be provided with shutters to exclude light when needed. Ventilation will be needed, and a moderate provision for this will suffice. We should arrange the shelving along the sides, with the pathway up the centre, forming the shelves of laths about three-quarters of an inch apart, the laths an inch thick by 1½ wide. The shelves should be about 18 inches apart. In addition to wooden shutters for the window and ventilators you will need straw shutters in severe weather over those openings, it being desirable to employ as little fire heat as possible. We have hot-water pipes in a flue, and let out the heat as required by sliding ventilators. The lower the temperature the better will it be for preserving the fruit, provided that frost is excluded.

**FUCHSIA LEAVES FALLING (E. R.).**—The leaves sent are, or rather have been, infested with red spider, which has destroyed their tissues and is the cause of the leaves falling. It may be destroyed by syringing the plants with a solution of soft soap 2 ozs. to a gallon of water, and could have been prevented by syringing in the evening moderately in dry hot weather.

**MELONS FAILING (N. N.).**—We do not see that your failure is attributable to any cause except that of a too dry atmosphere, which has induced red spider. The border ought not to be dry when the fruit is setting, and the atmosphere, though moderate dryness is desirable, should not be devoid of moisture. In dry hot weather we do not hesitate to syringe Melons lightly in the morning when in flower, and in a heated house, the chief points being to maintain a brisk heat, especially bottom heat, with thorough moisture at the roots, to impregnate the flowers, and leave on a little air at night as well as by day to prevent a close stagnant atmosphere. It is only when the Melons are ripening that dryness of the soil and atmosphere are needed. There is no reason why you should not grow either Cucumbers or Melons, the latter in summer if you wish, and the former in winter, without any fear of red spider.

**PRUNING NEGLECTED PEACH TREES (G. R.).**—The long shoots with laterals upon them we should cut back at once to where the shoots have eyes at the base of the laterals, removing the laterals close to whence they proceed, or if the shoot has no buds at the base of the laterals, cut back the shoots below the laterals. All forerights cut clean away to whence they issue. Your unfruitful Noblesse we should lift in November, or so soon as the leaves have fallen, take out a trench so far distant from the stem equal to the spread of the branches, cutting off all roots beyond the trench, and after lifting replant with the ball entire, and keeping a little higher than before, but avoid burying any portion of stem previously covered with soil. Make very firm about and over the roots, and mulch with littery manure. In spring thin-out the grossest wood especially if crowded, and with a season's growth you will, no doubt, have promise by the presence of bloom buds of a crop in the succeeding year.

**CHANGING VINES (W. M. G.).**—We should transfer Foster's Seedling from the late to the early house, it being an improvement on Royal Muscadine; but the others are so good that we know not which to advise you to displace. However, as Madresfield Court in the early house cracks we should transfer it to the late house. Your arrangement in neither house is good. Muscat of Alexandria in an early house with Hamburgs is not good, and Hamburgs in the late house are undesirable, as the Hamburgs in either case will be ripe before the others have well begun to colour. The object in your case has no doubt been to afford successional fruit over a lengthened period, and in that respect could not be better. Escholota is a confused name which may mean anything. Muscat Escholota is Muscat of Alexandria; Escholota, or an early Grape under that name, is Marchioness of Hastings; and another form of Escholota has splendid foliage and strong wood—this we have in an early house, ripening three weeks after Muscat of Alexandria and six weeks behind Black Hamburg. It is a shy bearer except it be pruned long, and is not distinguishable from Trebbiano, a late Grape, only in having more pointed berries. We should work your Escholota with Lady Downe's, which will hang much longer. Trebbiano to keep well requires to be kept rather warm and dry.

**ALOE UNHEALTHY (A. D.).**—The plants from your description are beyond recovery; they have probably been injured by frost last winter. We can only advise you to remove them to a greenhouse, assigning them a light airy position, seeing that the drainage is good and keeping rather dry. They should be kept from frost, but we apprehend that the plants are dead or nearly so.

**BIRDS TAME IN GARDEN (J. C.).**—Any bird that has one wing cut to prevent its flying away will gradually become tame. Even feeding them regularly and carefully avoiding frightening them will render them sociable. We saw a blackbird sitting on her nest in Mr. Webb's garden near Reading that was not at all disturbed by being closely looked at.

**APPLES (Mrs. Bracebridge).**—The Summer Golden Pippin can be obtained of any nurseryman. We do not know the Noble Candle, at least not by that name. "NORTHERN GARDENER" is not in the trade.

**FERN (E. Dervent).**—Send specimens with spores on them; we cannot name them without.

**SCARBOROUGH LILY AFTER FLOWERING (Maria).**—The bulbs of this, *Valloata purpurea*, keep in a light airy position, and repot between now and February, giving them a pot no more than 1½ or 2 inches larger, providing good drainage and removing the soil that comes away freely from amongst the roots, using a compost three parts fibrous loam, and one part leaf soil or

old dry cow dung, and a sixth of sharp sand. In potting do not remove the offsets, but let all grow together. They do not interfere with the larger bulbs, and in time they will flower. If you wish for more plants, then, of course, you will remove the offsets and put them singly in small pots.

**PLANTING FOR TIMBER (W. H. C.).**—We will answer your queries next week. A book such as you require is "The Forester," by James Brown, published by Messrs. Blackwood.

**COLEUSES FOR EXHIBITION (J. R.).**—The Coleuses which are ordinarily cultivated for their ornamental foliage are stove plants, and as such they should be judged at exhibitions.

**DRAINING A WALK (An Irish Subscriber).**—We make small cuttings in the grass at the sides and conduct to a drain with cesspools. It is important to catch the water before it accumulates to form a run strong enough to wash up the gravel. This may be rather costly, but is a much cheaper plan in the end than makeshifts. The cesspools have dish-cover stones, with grates let in to keep out anything larger than a quarter of an inch. The peaty bottom of a lake would not be a good dressing for an old kitchen garden, but formed into compost by an addition of a sixth of fresh unslaked lime, and laid up for three or four months, and turned over midway of the time, it would be a good application. Lilium bulbs will last any number of years in a favourable soil and under proper treatment.

**HARDINESS OF GNAPHALIUM LANATUM, &c. (Mrs. Forbes).**—It requires to be wintered in a house or pit kept rather dry and safe from frost. *Anemone japonica alba* and *Primula japonica* are both quite hardy, but both are benefited by a light mulching around the roots and up to the crowns with leaf soil or other light compost. All bedding plants would succeed in your soil where it well manured and liberally watered in dry weather, except such moisture-loving subjects as *Calceolarias* and *Violas*. Hardy edging plants that would succeed are *Antennaria tomentosa*, silvery, very dwarf; *Santolina incana*, silvery; *Arabis alpina variegata* aurea, yellow variegation; *Aubrietia purpurea variegata*, white variegation; *Eranthis radicans variegata*, white variegation; *Thymus variegata*, white variegation; *T. citrifolia* aurea marginata, yellow variegation; *Sempervivum californicum*, and Golden Feather *Pyrethrum*.

**SKELETONISING LEAVES (A. B. C.).**—Nearly all leaves may be skeletonised, but some require a longer time than others to become macerated. For instance, the seed vessels of the Winter Cherry, Henbane, and Poppy require a fortnight or three weeks if the weather be hot. Leaves of *Ficus elastica* (Indiarubber Plant) and *Magnolia grandiflora* require several months; leaves of the Tulip Tree, Poplar, and Maple a fortnight; leaves of the Holly and Ivy two or three weeks. Ferns require a long time, and so do the leaves of *Beggar's Broom*, *Butcher's Broom*, the Orange, Lemon, and Camellia. Great care must be taken in choosing the leaves, as the smallest speck spoils one. Many more should be placed in the water than are needed, as not more than one in twenty will be perfect. The time required depends on the weather. Beginners examine them too soon. The leaves should be put into soft water in a sunny situation, taking care that they are covered with water. Evergreen leaves may be skeletonised at any time, but deciduous leaves not before the end of June or beginning of July. Seed vessels must be operated upon when nearly ripe. When quite ready for skeletonising put the leaves into boiling water to remove the offensive smell. Remove the scum from the water. Brush off the pulp with a rather hard brush. If the leaves are tender bump them gently, which removes the pulp without disturbing the nerves of the leaves. Pour clean water over them until quite clean; put them on blotting paper to dry—a piece of glass is useful to brush them on. Tender leaves should be floated in water and caught on a card, as are fine Seaweeds. Bleach with chloride of lime and then wash them thoroughly with clean water, otherwise they become yellow. It is better not to bleach them until required for setting up. Thistles and Teazles look well when bleached, and aid much in arranging a group. The plant bearing the red berry is *Physalis edulis*, the Cape Gooseberry.

**FORMING A BED OF HEATHER (Edw. Wheeler).**—The best plan is to provide the proper soil—i.e., peat, though Heather will succeed in all soils, except, perhaps, limestone. Part off the Heather when but a few inches high, the dwarfier the better, securing about 8 inches thickness of soil, and either plant in clumps of about 9 inches square at that distance between each, or place them together as in turfing with grass turves, making firm. We have some which were made in both ways a few years ago, interspersing the larger clumps with double Gorse, which were masses of golden blossom in spring, and the Heather is now aglow with rosy purple.

**JARGONELLE PEAR UNFRUITFUL (Idem).**—It may arise from too close pruning, the bloom buds not unfrequently being terminal on shoots 6 or more inches long, but those you may distinguish now. They should be retained. The root-pruning must have been insufficient. We should again resort to it in autumn, allowing the trees to extend if you can.

**INSECTS ON APPLE TREES (Idem).**—The specimen leaf shows the trees to have been infested with aphids, the skeleton of one remaining, and the appearance of the leaf is a consequence of the aphides covering the upper surface of the leaves with a sweet glutinous substance resembling if not identical with honeydew, and forming a nidus for the fungus, with which the leaves are now covered. Syringe the trees now with a solution of soft soap, 2 ozs. to the gallon of water; and if this had been applied upon the appearance of the aphids, it being most prevalent on the under side of the leaves, and repeated occasionally, the leaves would not have been in their present state. The syringing with the soapy solution should be followed by a thorough washing with the garden engine to cleanse the foliage of the obstruction caused by the fungus.

**DESTROYING WIREWORM (David Sykes).**—It is a difficult pest to deal with. Nitrate of soda is good against wireworm and other vermin especially elugs, applying it at the rate of 1 lb. per rod, 804 square yards; but a more effectual mode of riddance is by a dressing of gas lime pointed in with a fork at the rate of twenty bushels per acre, or half a peck per rod. It should be applied in spring at the time of planting or sowing.

**INSECTS IN VINERY (West York).**—Thrips may be destroyed by fumigating with tobacco smoke, but the smoke will not kill red spider. See Mr. Douglas's remarks on destroying this pest in this week's "Doings."

**FERN (G. McD.).**—It appears to be a variety of *Cystopteris fragilis*, and is very elegant and graceful.

**NAMES OF PLANTS (H. S. H.).**—It appears to be *Funkia subcordata*; but we cannot name plants from leaves only. (G. McG.).—1, Bog Pimpernel (*Anagallis tenella*); 2, *Atriplex hortensis*. (Caroline).—You are quite right, it is the wild Guelder Rose (*Viburnum opulus*). (Constant Reader).—1, *Heterocentron roseum*; 4, *Centrostemma multiflora*; 6, *Bou-*

gainvillea spectabilis. We cannot name florists' Begonias, or specimens without flowers. (J. A.).—1, Rumex conglomeratus; 2, Triglochin palustre; 3, Senecio sylvaticus. (J. W.).—Chrysanthemum foniculaceum or C. frutescens. (M. H. R.).—Achillea ptarmica (double-flowered var.). We cannot name the Davallia without fruit. (E. C.).—Your letter reached us ten days after date, and the plant was quite unrecognisable.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### WEYMOUTH POULTRY SHOW.

UNDER favourable auspices this Show was held on the two last days of August. The place of exhibition was the Market House, which the Committee made extremely attractive with flags and banners and pots of hothouse plants. Every here and there, too, among the cages were bouquets of bright flowers, which made the effect very pleasing. The Secretary and Committee worked cheerfully and seemed very anxious for everyone's welfare. We venture to think that this will become a leading Show. Mr. Hewitt judged the poultry, Mr. P. H. Jones the Pigeons, and Mr. Billett the Cage Birds. In many classes the competition was small, but the quality was of a high standard throughout.

Four classes of *Dorkings* came first in the catalogue. A very fine pair of Darks were first in the coloured adults. The hens were large and good in colour, the cock promises to come out of his moult a very large bird. We did not like the second pen quite so well as the third, but neither were in very good looks. In chickens the winners won easily, and they were a very large and well-grown pair. In Silvers the first also took the cup. The cock in this pen is of very beautiful colour and of immense frame. A good pen of Silvers took first in chickens, and the second were almost as good, the third smaller but much younger. In *Cochins* the first adult Partridges were very large; the cock has peculiarly smart hackles, and was in fine condition. Buff chickens were also good. The cup pen contained a charming pullet good in colour and neat in head. Variety *Cochins* brought several good cocks, but the hens mostly ragged and untidy. In chickens the first were not good in colour and must have been very early hatched. The second were very white and well feathered but much younger. Third went to pretty Blacks. In Dark *Brahmas* the cup hen was huge and wonderfully fluffed, though rather brown. In chickens the pullet was very clear in markings, but we did not quite like the cockerel's comb, still they were well first. In adult Light *Brahmas* the first and second seemed very equal in merits; the second cock, perhaps, the larger, but the first more compact in shape. In chickens the first pullet was very neat in head and shape. In *Game* the cup went to stylish Black Red chickens, the cockerel being a well-shaped bird. *Hamburgs* were a fair collection. A pen of Golden-pencilled chickens won first and cup. The adult Blacks were very lustrous and good. In White *Leghorn* chickens the prize birds were not quite white enough in ears or quite large enough for our taste. We fancied we noticed a hen in Mr. Fowler's pen of chickens, and a cockerel in his pen of adults. *Polands* were extremely good. In the class for old birds a good pen of Golds won the first prize, and Blacks second. The hen in the latter pen very good indeed. In chickens a very smart pen of Blacks were first, and a capital pen of same colour second. These were more forward than the first. Very good Silvers were third, the pullet's crest well laced. *Malay* chickens were very fine and as good a class, we thought, as any of the chicken lots. The first were very large and won the section cup. The cockerel seems to have, too, plenty of growth in him yet. In Black *Spanish* a good pen of adults (Allsopp) were rightly passed, the cock having had his comb unmistakably cut. In chickens a fairly good pen were first, but not either of the Oundle pairs we are told. In *French* the cup went to good old Crêves. The second were also good, but the hen's crest had a good deal of white in it. In the Variety class a large pen of La Flèche were first, and good Silkie second.

In *Bantams* the classification was not good, and Piles and Duckings had to go to the Variety class. The winners in Brown Reds were pretty, the third cockerel undubbed. In the Variety class Black-booted won first, and White-booted second, both good of their colour. The Selling classes were only fair; the first Buff pullets perhaps the best in the collection. We were sorry to find no Duck classes, for there was space in the hall for both them and Geese.

The *Pigeons* were not very large classes. There was a point cup which was won by Mr. Yardley with eighty-four points, Mr. Vander Meersch coming second. Carriers were not superior, the first Black cock being the best bird by far. In Pouters a good White hen won in her class. Blue Dragons were extremely good, the first and second cocks being well selected in a difficult class. In Variety hens a pretty White was second. We believe Mr. Wood's birds did not arrive until after the judging. The first Almond Tumblers matched very fairly. All the Antwerps were in one class, and this really is not fair to judge or exhibitor. In Nuns the first were very good. The

black in front came down a little too low for our taste, but the colour was bright. In Turbitts the first were Blues and the second Yellows. Fantails made a small class, but the pens were too small for them, and did not show them to advantage. In Jacobins the first were Reds. We thought, as did several others, that they had been rather "set in order." In the Variety class very pretty Frillbacks were first and Ice Pigeons second. Mrs. Drummond won an extra prize in this class with a pair of Crown Pigeons from New Guinea. They were extremely handsome, and when the sun shone upon them their colours were simply gorgeous. Their crowns are certainly very striking, looking as if made of shreds of purple-blue tatarian. In the Selling class a nice pair of Archangels won first.

In the *Birds* Mrs. Drummond was very successful, her Ticked Belgian being very good and showing himself to great advantage, not being in the least shy. A gorgeous foreign Starling winning easily first in his class. The Parrots were very fair. A very pretty White Cockatoo we noticed on a looking-glass stand, but it was ticketed "Too late for competition." The following are the awards of the Judges:—

**POULTRY.—DORKINGS.—Coloured.**—1, T. C. Burnell. 2, G. Watson. 3, Mrs. C. J. Radclyffe. *Chickens*.—1, T. C. Burnell. 2, R. Cheeseman. 3, S. Newick. *Any other variety*.—1 and Cup, O. E. Cresswell. 2, Miss E. Neville. 3, J. Jesty. *Chickens*.—1 and 2, T. C. Burnell. 3, O. E. Cresswell. **COCHINS.—Partridge.**—1, H. Tomlinson. 2, J. Carré. 3, H. S. Hansford. *Chickens*.—2, Mrs. C. J. Radclyffe. *Cinnamon and Buff*.—1, H. Tomlinson. 2, S. R. Harris. 3, Mrs. C. J. Radclyffe. *Chickens*.—1 and Cup, Rev. G. F. Hodgson. 2, Miss C. Brooke. 3, Leys. *Any other variety*.—1, Mrs. W. C. Drummond. 2, A. Darby. 3, Mrs. J. T. Holmes. *Chickens*.—1, S. R. Harris. 2, Rev. R. S. Woodgate. 3, J. T. Holmes. **BRAHMAS.—Dark.**—1, Cup, and Mrs. C. J. Radclyffe. 2, J. F. Smith. *Chickens*.—1, E. Fritchard. 2, H. Feast. 3, Mrs. C. J. Radclyffe. **Light.**—Mrs. W. C. Drummond. 2, Mrs. J. T. Holmes. 3, J. Turner. *Chickens*.—1, J. Turner. 2, F. C. Mace. 3, H. ### BINGLEY SHOW OF POULTRY, &c.

The tenth annual Show was held in the Myrtle Park, Bingley, on the 29th ult. The following is a list of awards:—

**POULTRY.—GAME.—Black or Brown Red.—Cockerel.**—1, T. Dyson. 2, J. Spencer. 3, E. Lund. **Pullet.**—1, T. Dyson. 2, E. Lund. 3, H. Fortane. *Any other variety.*—Cockerel.—2, T. Dyson. 3, J. A. & H. H. Staveley. **Pullet.**—1, H. C. & W. J. Mason. 2, J. A. & H. H. Staveley. 3, M. Jowett. **COCHINS.—Buff.**—1, Mrs. A. Findall. 2, C. Sidgwick. 3, G. H. Proctor. *Any other colour.*—1 and 3, C. Sidgwick. 2, R. F. Percival. **BRAHMAS.—Dark.**—1, R. F. Percival. 2, E. Fritchard. **Light.**—2, R. F. Breeze. 3, R. P. Bann. 3, M. H. SPANISH.—1, J. NEWTON. 2, J. Roberts. 3, J. Thresh. **DORINGS.**—1 and 2, T. Briden. 3, R. H. Felton. **POLANDS.**—1, W. Harvey. 2, H. Bowker. 3, J. Fearney. **FRENCH.**—1, G. W. Hibbert. 2, J. E. Clayton. 3, F. H. Stericker. **HAMBURGS.—Gold-spangled.**—1, G. & J. Duckworth. 2, W. Driver. 3, T. Dean. **Silver-spangled.**—1, H. Pickles. 2, J. Fawcett. 3, O. Paley. **Gold-pencilled.**—1, J. G. & J. Duckworth. 2, W. Anderson. 3, W. Clayton. **Silver-pencilled.**—1, J. Smith. 2, H. Smith. 3, G. & J. Duckworth. **Black.**—2, C. Bann. 3, G. F. Jagg. *Any variety.*—1, G. & J. Duckworth. 2, E. Gill. 3, J. Preston. **BANTAMS.—Game.**—1, W. Shaw. 2, W. H. Robinson. 3, A. S. Sugden. *Any other variety.*—1, C. & J. Illingworth. 2, W. H. Shackleton. 3, F. Beandlan. **SELLING CLASS.—Cock.**—1, J. Berry. 2, J. Sharp. 3, S. W. Hallam. **Hens or Pullets.**—1, S. Lucas. 2, G. Moore. 3, C. Carr. **PIGEONS.—CARRIERS.—Cock.**—Cup and 2, R. Fulton. 3, H. Yardley. **Hen,**

—1, R. Fulton. 2, C. G. Cave. 3, W. H. A. Miller. *Young*.—1, R. Fulton. 2, W. H. A. Miller. 3, C. G. Cave. *Pouters*.—*Cock*.—Cup, R. Fulton. 2, H. Pratt. 3, E. A. Thornton. *Hen*.—1, R. Fulton. 2 and 3, H. Pratt. *Tumblers*.—*Almond*, *Short-faced*.—Cup and 3, R. Fulton. 2, R. Cant. *Any other variety*, *Short-faced*.—1 and 2, R. Fulton. 3, J. Cargill. *Long-faced*.—1, J. Cargill. 2, W. Ellis. 3, R. Woods. *Barbs*.—1 and 2, R. Fulton. 3, H. Yardley. *Overs*.—*English*.—Cup, R. Fulton. 2, W. Ward. 3, E. Lee. *Jacobins*.—*Red or Yellow*.—1, W. Dugdale. 2, E. E. M. Roys. 3, R. Fulton. *Any other colour*.—Cup and 3, R. Fulton. 2, E. E. M. Roys. *Dragoons*.—*Blue or Silver*.—Cup, R. Woods. 2 and 3, W. Smith. *Any other colour*.—1 and 3, R. Woods. 2, J. Eeroyd. *Young*.—1, W. Smith. 2, R. Woods. 3, J. Ratcliffe. *Fantails*.—1 and 2, J. F. Loversidge. 3, J. Walker. *Turbits*.—Cup, R. Fulton. 2, R. Woods. 3, E. A. Thornton. *ANY OTHER VARIETY EXCEPT ANTWERPS*.—1, G. Alderson. 2 and 3, R. Fulton. *SELLING CLASSES*.—*Single Bird*.—Cup, C. G. Cave. 2, E. A. Thornton. 3, R. Woods. *Pair*.—1, J. Thresh. 2, T. E. Hainsworth. 3, A. E. Byford. *ANTWERPS*.—*Short-faced*.—*Cock*.—1, 3, and *vhc*, J. Eeroyd. 2, J. Wright. *Extra* 2, W. Harrison. *Hen*.—1, W. Harrison. 2, J. P. Rothwell. 3, J. Eeroyd. *Medium-faced*.—*Cock*.—1 and 3, J. Eeroyd. 2, J. J. Bradley. *Hen*.—1 and 3, W. Ellis. 2, J. Wright. *Long-faced*.—*Cock*.—Cup and 3, W. Ellis. 2, J. Lister. *Hen*.—1, B. Rawnsley. 2, W. Ellis. 3, J. Eeroyd. *vhc*, H. Jennings. *Medium-faced*.—*Young*.—1 and 2, W. Ellis. 3, J. Lister. *Long-faced*.—*Young*.—Cup, J. Lister. 2, B. Rawnsley. 3, W. Ellis. *Local Class*.—1, W. Lund. 2 and *vhc*, F. Lister. 3, B. Rawnsley.

JUDGES.—*Poultry*: Mr. R. Teebay, Fulwood, Preston; Mr. J. Dixon, Clayton, Bradford. *Pigeons*: Mr. T. J. Charlton, Bradford; Mr. J. Crosland, Wakefield.

## TODMORDEN SHOW OF POULTRY, &c.

THE seventh annual Show was held on the 2nd inst. Most of the poultry were young birds. As we have remarked before, there seems to be a great dearth of good forward birds of this year, although some of good quality cropped up, as for instance the Brown Red Game and Messrs. Duckworth's grand Hamburgs, the pens of which have been well to the front.

In *Game* a pen of Black Red chickens won the cup, the next candidates being a nice pen of Duckwings. *Cochins* were grand in colour, but we have an impression of their being rather small and light in bone for the age. *Buffs* won in one class, and *Whites* in the other. *Hamburgs* a small entry; by far the best, considering the condition of the Gold-spangles, being the Silver-pencils and an exquisite pen of Blacks. *Bantams*, a good entry and the competition keen. In Reds were some of the best we ever saw brought together at this time of year, style, quality, colour, and feather being about perfect. Other than Reds two excellent pens of Piles won, and it was difficult to decide upon the merits of the two. Any other Bantams, the winners Blacks. One exquisite pen of Silver Sebrights would have occupied a position, but that the pullet has a yellow beak. In the Variety class first and second were Red Malays, and to the first pen was awarded the cup for the best pen in the Show, *Game* excepted. These are an extraordinary pair. The Selling class of Ducks was better than the poultry, although the winners were good in the latter class. In the district competition the medal for the best pen was awarded to Mr. W. Ormerod for a capital pen of old Brown Red Game fowls.

*Pigeons* were a very good entry. Mr. Baker putting in appearance quite astonished the public, but, however, he gave them something to look at, which we consider is a great point at these exhibitions. The cup for the best pen was won by that gentleman with a capital Black Carrier cock. Many of the *Pouters* were in miserable plight and needed a vacation, but the winning Blue hen kept up wonderfully. *Tumblers* in both classes very good. In the variety of *Tumblers* the *Beverley* purchase keeps cropping up. *Dragoons* a fair class, but not what we generally see. *Fantails* good and the winners *White*. *Barbs* a fair lot, and *Jacobins* good, Reds winning in the latter class. In *Antwerps* was severe competition, and the classes as a whole being very good in quality. We heard of a second purchase of six birds for £80. *Turbits* were a good lot; the first-prize Black was claimed at £5 and quickly sold for much more. In the Variety class first was a *Blondinette* and second a Black Fairy Swallow, to our mind one of the most handsome birds in the fancy.

*Rabbits* had six classes and fifty-one entries. In Lops Mr. Pepper's well-known doe was first, and a nice Fawn-and-white second, Messrs. Fell's Black-and-white buck not being in condition. *Angoras* were very good; the first perfect, but that the buck is a little moulting; second one of the finest-woolled specimens ever seen, but young and small; a recent winner only very highly commended. *Himalayans* poor except the winners. *Silver-Greys*, the Cottingham winners in grand order, second a fair Rabbit. Any other variety the champion Silver-Cream, second a moderate Belgian Hare, and several other fair Rabbits noticed. The Selling class was a good one; first an *Angora* and second a lop.

POULTRY.—*GAME*.—*Black Red*.—1 and Cup, J. Fletcher. 2, J. Greenhalgh. *Brown Red*.—1, J. F. Walton. 2, T. Dyson. *Any other variety*.—1 and 2, T. Dyson. *Any colour*.—1, C. W. Brierley. 2, W. Ormerod, jun. 3, B. M. Wilkinson. 2, Dawson & Greenwood. *vhc*, R. Southern. *COCHINS*.—*Partridge* & *Buff*.—1 and 2, C. Sidwick. *vhc*, J. Walker. *Any other colour*.—1 and 2, C. Sidwick. *DORKINGS*.—1, J. Stott. 2, J. Walker. *SPANISH*.—1, J. Powell. 2, J. Thresh. *HAMBURGERS*.—*Gold-pencilled*.—1, G. & J. Duckworth. *Gold-spangled*.—1 and 2, G. & J. Duckworth. *Silver-pencilled*.—1, G. & J. Duckworth. 2, H. Smith. *Silver-spangled*.—1, T. Stottard. 2, A. Trickett. *Black*.—1, C. Sidwick. 2, T. Stottard. *vhc*, C. Sidwick. *Wentworth*.—*Bantam*.—*Game*.—*Black* or *Brown Red*.—1, A. S. Sugden. 2, W. F. Entwistle. *vhc*, W. F. Entwistle. E. Walton. *Game*, any other variety.—1, W. F. Entwistle. 2, F. Steel. *vhc*, E.

Walton, F. Steel. *Any other variety*.—2, C. & J. Hingworth, J. Walton. *vhc*, J. Walker. *FRENCH*.—1, J. & E. Clayton. 2, J. Broadley. *POLANDS*.—1, J. Fearley. 2, J. Parlington. *ANY OTHER VARIETY*.—1, J. F. Walton. 2, A. Smith. *SELLING CLASS*.—1, F. Steel. 2, J. Powell. 3, W. A. F. Fenwick. 4, T. Cropper. 5, W. Bentley. 6, J. F. Walton. *DUCKS*.—*Aylesbury*.—1 and 2, J. Walker. *Rouen*.—1 and 2, W. H. Rothwell. *Any other variety*.—1 and 2, J. Walker. *vhc*, J. Booth. *SELLING CLASS*.—1 and 2, J. W. Rothwell. 3, C. Holt. *GEES*.—1 and *vhc*, J. Walker. 2, J. Shackleton. *TURKEYS*.—1, J. Walker. 2, T. & J. Sunderland.

LOCAL CLASSES.—*COCHINS*.—1, C. Holt. 2, T. Matthew. *BRAMHMS*.—1, C. Holt. 2, J. Chadwick. *BANTAMS*.—1, T. Cropper. 2, H. Crabtree. *HAMBURGERS*.—1, J. H. Fletcher. 2, J. Chadwick. *GAME*.—1 and Medal, W. Ormerod, jun. 2, G. Higgin.

PIGEONS.—*Pouters*.—1, W. Harvey. 2, J. Baker. *CARRIERS*.—1 and Cup, J. Baker. *TUMBLERS*.—*Almond*.—1 and 2, J. Baker. *Any other variety*.—1 and 2, J. Baker. *DRAGONS*.—1, R. White. 2, J. Eeroyd. *FANTAILS*.—1 and 2, J. Baker. *BARBS*.—1, M. Hedley. 2, J. Baker. *vhc*, J. Stanley. *JACOBINS*.—1, W. Dugdale. 2, J. Baker. *ANTWERPS*.—*Long-faced*.—1, J. Eeroyd. 2, S. Wade. *vhc*, C. Hopwood. *Medium-faced*.—1, J. Eeroyd. 2, W. Harrison. *Short-faced*.—1 and 2, J. Eeroyd. 2 and *vhc*, W. F. Entwistle. *TURBITS*.—1, S. Dyson. 2, J. Baker. *TRUMPETERS*.—1, W. Harvey. 2, J. Baker. *OWLS*.—*English*.—1 and 2, J. Baker. *Foreign*.—1 and 2, J. Baker. *BLUE ROCKS*.—1, J. Bairstow. 2, J. W. H. Fielden. *NUNS OR MAGPIES*.—1, Gardner & Kendall. 2, F. Schofield. *FLYING PURPOSES*.—1, W. Harvey. 2, A. Stansfield. *Extra* 2, W. Brown. *ANY OTHER VARIETY*.—1, W. Harvey. 2, W. Harrison. *FLYING PURPOSES*.—Open only to birds marked with the Todmorden Homing Society's stamp.—1, W. Bentley. 2, W. Crossley. *SELLING CLASS*.—1, W. Harvey. 2, J. Baker. *RABBITS*.—*LOP-EARED*.—1, E. Pepper. 2, E. Murgatroyd. *ANGORA*.—1, R. Murgatroyd. 2, F. Johnson. *vhc*, T. & E. J. Fell. *HIMALAYAN*.—1 and 2, J. Chappell. *SILVER-GREY*.—1, T. & E. J. Fell. 2, H. Woods. *ANY OTHER VARIETY*.—1, E. Pepper. 2, Miss S. Maude. *SELLING CLASS*.—1, S. A. Clegg. 2, R. Murgatroyd.

CATS.—1, T. Tasker. 2, J. Stansfield. 3, F. W. Barritt. JUDGES.—*Poultry*, *Rabbits*, and *Cats*: Mr. E. Hutton, Pudsey, Leeds; Mr. R. Payne, Brierfield, Burnley. *Pigeons*: Mr. J. Hawley, Bradford.

## COTTINGHAM SHOW OF POULTRY, &c.

THE annual Show was held in the beautiful grounds of Mrs. Gee, on Wednesday, the 30th ult. The weather was fine till the latter part of the day, when severe thunder showers fell. Poultry, &c., were in the open air, the former under the clumsy old bee-hive-shaped wickerwork pens, which are unsuitable for the purpose and unattractive, and we can assure the Committee the entries will never be good till these antiquated pens are dispensed with. There were no special prizes, and the poultry were but poor, all being young birds, a mistake at a Show like this.

The *Game* and variety *Bantams* and *Fancy Ducks* were by far the best, and very good.

*Pigeons*, on the contrary, were provided with Messrs. Turner's pens, and many extra prizes being given the entries were very good, as also the quality, Mr. Baker taking the majority of the prizes and specials—in fact, a good haul with a capital stud.

*Rabbits* were a capital entry; the prizes—15s., 10s., and 5s. in five classes—brought seventy-five entries, and the quality was such as has never been seen at Cottingham before. In Lops first was a Black-and-white, good in most points; second a Black-and-white-buck; extra second an immense doe, Black-and-white, 21½ by 4½; third a Fawn-and-white buck, 22½ by 4½. Some splendid specimens had very crooked legs, and were passed over. *Silver-Greys* were a grand class, the first being a most handsome specimen, very young, but perfect in shade and silvering, and one that was left out at Rochdale; second was the first winner at Rochdale, very dull and mealy in appearance; third dark on nose, but otherwise perfect. The second at Rochdale, which is very deep in moult, was very highly commended. *Himalayans* a capital class, and honestly shown. The Selling class contained some good specimens—Lop, Silver-Grey, and Dutch winning. The Variety class was a large one, many cracks being gathered together. First was the well-known Silver Cream so often commented on; second a well-known Belgian Hare, remarkably handsome; extra second *Angora*; and third also Belgian Hare.

*Cage Birds* were a fair lot, and placed under one of the extensive marquees, Mr. Coker's stud being a show in themselves. Grey Parrots were pretty good, but the choice of the lot was the King Parrot shown by Mr. Coker, which is without exception the best we have ever seen. Any other Foreign bird—first a Leadbeater Cockatoo, good in all points, a piping Crow; third a long-tailed Wydah. Canaries were not equal to the Foreign birds, the point prize for these falling to Mr. Ostler, Hull.

POULTRY.—*SPANISH*.—1, R. Newbitt. 2, Recab, Stabler, & White. *DORKINGS*.—1, R. A. Maxsted. 2, Recab, Stabler, & White. 3, J. Fryer. *COCH-CHINS*.—1, W. Saxon. 2, Recab, Stabler, & White. *GAME*.—*Cock and Pullet*.—1 and 3, W. & H. Adams. 2, F. Stamford. *Cock*.—1 and 2, W. & H. Adams. 3, F. Stamford. *POLANDS*.—1 and 2, A. & W. H. Silvester. 3, Harrison. *HAMBURGERS*.—*Gold or Silver-spangled*.—1, J. Stottard. 2, H. Thurlow. *Gold or Silver-pencilled*.—1, W. W. Harcliff. 2, J. A. Holmes. *BRAMHMS*.—1, B. Best. 2, H. Straker. 3, W. Scott. *BANTAMS*.—*Game*.—1, H. Elwes. 2, R. Newbitt. 3, H. M. Eames. *Any other variety*.—1, J. F. Phelps. 2, J. N. Proctor. 3, Recab, Stabler, & White. *Any variety*.—*Cock*.—1, R. Newbitt. 2, W. Morris. 3, Recab, Stabler, & White. *DUCKS*.—*Aylesbury* or *Rouen*.—1, W. Fiery. 2, Igarate. *Any other variety*.—1, 2, and 3, A. & W. H. Silvester. *ANY OTHER VARIETY*.—1, J. Stottard. 2, Recab, Stabler, & White. 3, H. Thurlow. *SELLING CLASS*.—1 and 2, Recab, Stabler, & White. 3, Mayfield. *EXTRA CLASS*.—1, Mayfield. 3, Major Fawcett.

PIGEONS.—*Pouters*.—*White*.—1 and 3, A. Spencer. 2, W. Harvey. *vhc*, J. Blanchard. *Any other variety*.—1, H. R. Tenney. 2, W. Harvey. 3, J. Baker. *vhc*, J. Baker. *H. R. Tenney*.—*BRAMHMS*.—*Special* 1 and 2, J. Baker. 3, E. Gaby. *vhc*, J. Baker. *W. & H. Adams*.—*TURBITS*.—1 and 2, J. Baker. 3, T. S. Stephenson. *vhc*, R. Woods. J. Blanchard. *JACOBINS*.—1 and 3, J. Baker. 2 and *vhc*, J. Blanchard. *FANTAILS*.—*Special* 1 and 2, J. Baker. 3, J. N. Proctor.

*vhc.* J. F. Loversidge. DRAGONS.—1, R. White. 2, J. Baker. 3, R. Woods. TUMBLERS.—Special 1, 2, 3, and *vhc.* J. Baker. ANTWERPS.—1 and 3, R. White. 2, F. R. Edwardson. BARBS.—1 and 2, J. Baker. 3, H. Crosby. ANY OTHER VARIETY.—Special 1, W. Harvey. 2, J. Baker. *vhc.* H. Crosby. SELLING CLASS.—*Pairs or Single*—1, W. Harvey. 2, F. R. Edwardson. W. & H. Adams. 3, C. Wroot. *vhc.* J. Blanchard. R. White (2), W. & H. Adams. CABBITS.—LOR.—1, E. Pepper. 2, T. & E. J. Fell. Extra 2, T. Myton. W. & H. A. Horner. 3, J. Noble, jun. *vhc.* J. Falding. T. & E. J. Fell. SILVER-GREY.—1, T. & E. J. Fell. 2 and *vhc.* H. Duck. 3, T. Myton. HIMALAYAN.—1 and 2, T. & H. Duck. 3, J. W. Atkinson. SELLING CLASS.—1 and *vhc.* T. Myton. 2, E. Pepper. T. & E. J. Fell. Extra 3, E. Robinson. ANY OTHER VARIETY.—1, E. Pepper. 2, E. Robinson. Extra 2, T. & E. J. Fell. 3 and *vhc.* T. Myton. Extra 3, T. & H. Duck. CAGE BIRDS.—PARROT.—Grey African.—1, R. Smith. 2, C. Glover. Any other variety.—1 and 3, J. Coker. 2, Sir T. A. Constable. PARROQUET OR LORY.—1, R. Durden. 2, G. Coker. 3, J. Coker. LOVE BIRDS.—1 and 3, J. Coker. 2, W. G. Furdon. ANY OTHER VARIETY OF FOREIGN BIRD.—1, Special, and Extra 3, J. Coker. 2, C. A. Glover. 3, J. C. Griffin. CANARIES.—Belgian.—1, W. Forth. 2.—Ostler. 3, C. J. Salt. Norwich.—1, C. J. Salt. 2, G. Ostler. Extra 2, W. Forth. Marked, any breed.—1, G. Ostler. 2, C. J. Salt. LARKS.—1, J. Barnes. 2, T. Kirk, jun. BRITISH BIRDS.—1, R. Toogood. 2, J. Barnes. 3, G. Coker.

JUDGES.—Poultry and Rabbits: Mr. E. Hutton. Pigeons: Messrs. Hawley and Hutton. Game Birds: Mr. L. Mennikie.

### DISEASES OF PIGEONS.

The symptoms of the Pigeon which I lost, as I believe from inflammation of the lungs, were rather different from those described by Mr. Hutchinson as being indicative of bronchitis. The bird never lost its inclination to eat, but seemed unable to pick up the peas. The only other symptoms were extreme difficulty in breathing, and for some hours before death a most distinct clicking in the lungs could be heard even at a distance of some yards. The bird was removed from the house and brandy and water administered. On the third day, when too late, I applied a mustard plaister between the shoulders, which gave it some relief, but it was not soon enough to save it. When opened the lungs proved to have been very much inflamed, with a great deal of froth about them, and some clotted blood was found near the heart.

I have been much troubled with canker this year, and lost a great many young Pigeons from that disease; I should therefore feel grateful for suggestions. Some birds have been very much more unfortunate than others, having lost all their young, while others again have not lost one from that cause. Does not this look as if there was some natural tendency to this disease in the young birds inherited from their parents? This question of the disease being hereditary is most important, as, if it does not exist, there can be no reason for destroying good birds simply because they have been unfortunate with their families. I may mention that my birds are well housed, kept clean, and fed on white peas and dari in the morning.—E. B. T.

I FIND the forms of disease are so numerous and puzzling that, in the words of Lord Dundreary, they are things that "no fellow can understand;" but nevertheless, I still venture to assert that Pigeons are often amenable to treatment, and that I have in my lofts healthy breeding birds that would have undoubtedly died if left to themselves. I can give many instances, but will take two of the most remarkable. I bought a prize Pouter cock two years ago. When he arrived here he was scouring badly. I took every care of him; gave him Walton's paste, sulphate of iron in his water, powdered chalk, opium pills, and crammed him with beans without any effect; he got worse and worse, and became so weak and thin as to be unable to stand, and did not eat a grain himself for several days. I happened to have seen a letter in your journal asserting that scouring was caused by worms. I took an eggspoonful of powdered area nut, mixed it with powdered chalk and Walton's paste, water, and two grains of opium, and put it down his throat. The next morning he had passed a round worm 2 inches long, similar to those that horses are sometimes infested with; he began to feed the same evening, became perfectly well in four or five days, has bred for two seasons, won twice, and I have three birds by him here at this moment. The same year I bought an imported Black Russian Trumpeter. A short time after I received him I observed him amiss—picked him up, and found he had a large tumour on the lower part of his crop, externally as large as a five-shilling piece, of a yellowish colour, with an internal hard core firmly attached to the top of the breastbone, and as large as a hazel nut. It looked so bad a case that, although I had given a large price, I was on the point of killing him, but resolved on trying iodine. I first plucked off the feathers, and painted heavily with tincture of iodine. In three or four days the tumour was considerably reduced, and after three applications at intervals of a week disappeared entirely. He is now alive, has bred well, and won two first prizes since. Now, as to disease being hereditary, none of this bird's young have had a stiff wing or tumour of any kind.

With respect to the canker in the young birds, I have never had many cases of it, but curiously enough have had two this year, one in a pair of young Trumpeters, under feeders; and another in a pair of Pouters, also under feeders. In the case of the Trumpeters they were apparently at night both doing well; the next morning I found one of the two dead, his crop full, and his mouth full of blood. On opening him I found a large tumour

loosely attached to the inside of the throat, which had, I think, choked and caused him to break a blood-vessel in the head. Had I perceived it I believe it might have been pushed down the throat; if the place had then been dressed with caustic I think the bird would have lived and done well. The other young one was reared, fed himself, and did well till he died a day or two since in moulting. The case of the young Pouters was somewhat similar; apparently well overnight, in the morning the head of one of them was dreadfully swelled, and the bird dying. I killed him, and found a tumour behind his eye. This case was evidently incurable, as the cancer was not confined to one place, but involved the whole head and neck. The other young one did well, is a particularly large handsome bird, and is now nearly through his moult. In both these cases none of the earlier and later young birds from the same parents have shown any signs of canker, and are all quite healthy. I think that canker comes from the feeders, and not from the parents.

A "PUZZLED FANCIER" should change a pair eggs from the birds that breed cankered young to a pair that breed healthy birds. If they still turned out cankered it would go a long way to prove that his view is right; but even if this did happen I think it quite possible that they might not breed a single cankered bird next season.

I have a large number of birds, some chiefly feeders, and young birds fly at liberty. The others are confined in lofts and aviaries in three or four places at a distance from each other. Last season I lost fully three-fourths of the young birds hatched from the second and third round of eggs by a disease I had never seen before, and have not had a single case of this year. They all died at about ten days old of disease of the liver, which grew to an enormous size and was full of yellow pustules. The old birds were apparently quite healthy, and none of them died of it, and the disease attacked all the varieties indifferently, the feeder's own young birds dying just as freely as the more delicate birds. I think "PUZZLED FANCIER" must admit that it was not a case of hereditary taint. Since I wrote to you last I have had another very bad case of bronchitis in a two-year-old and very valuable bird. I have treated him in the way I stated in my last letter, and he appears to be in a fair way to recover.—J. H. HUTCHINSON.

### CANARY MANAGEMENT IN OLDEN TIMES.

No. 3.

In the Journal of July 27th, page 84, I promised to state in a future chapter Mr. Hervieux's method of making a composition for young Canary birds, which, as the writer observes, "may serve a fortnight at least without being spoiled."

"Take half a pint of rapeseed and bruise it very well in a large mortar, or on a smooth table, running a wooden roller over it several times, so that the seed being well broken you may cleanse it from the husks; add to it three little dry sinels bruised and reduced to powder after having taken off the first crusty part; add to it a penny biscuit. All this being well mixed together and reduced to powder, put it into a new wainscot [deal] box, and set it in a place that is not exposed to the sun. Take a spoonful or more of this powder as you have occasion, and your birds' food will be made in a moment, adding to it a little of the yolk of an egg, and a drop of water to moisten the whole. But you must not give your Canary birds this powder above twenty days at most, for after the said term the powdered rapeseed which is in the composition, though dry, grows sour, and when water is put to has a taste like mustard, which cannot but be hurtful to your young birds."

Mr. Hervieux's advice is not to make too large a quantity of the composition at one time, for being kept in a deal box is (owing to the soft nature of the wood), apt to breed worms. He further says, "After twenty days at most, if you have any of this composition left you may give it in the dry prepared state to the old cocks and hens, which will eat it heartily without receiving any hurt by it."

A recipe for a similar composition to the above, the only alteration being the omission of the dry bruised rapeseed, is given for young birds in their earliest stage of youth—from the chipping of them until they are four days old. The writer appears to have much favoured the system of bringing-up young birds by hand, or of providing the means by which it might be effected. He says, with a drop or so of water moisten the composition, and "tempering all well that there may be no hard lumps. This paste must never be too thin, because if so it does not nourish them so well, and they are continually craving; besides that when it is too wet they, the birds, are often loose and scarce recover it. When the paste is somewhat stiff it lies longer in their craws, and nourishes them better. When the hard egg is new the white dissolves as well as the yolk, and does not heat them so much as if there were only the yolk. When the first three days are past, and I perceive my young birds gather strength, I add to the composition a small quantity of rapeseed boiled without bruising, they being then able to digest that seed, but the said rapeseed must be washed in cold

water after having just boiled-up, for it then nourishes the little birds without heating them. Now and then I give them a sweet almond blanched and reduced to powder, which I mix with their paste. When I perceive the little birds are somewhat heated I put in a pinch of the seed of chickweed. This composition is to be made twice a-day in very hot weather, because everything that goes to the making of this paste soon grows sour. This is, in short, what I use to bring-up little Canary birds by hand. . . . If you make use of this last composition you may be assured your little ones will come to good, and if you rear-up forty by hand scarcely one will die." Not a bad task certainly for anyone wishing to enter into the pleasure and mystery of Canary-breeding.

Again: "If it happens that any of your little Canary birds are sick, which is not strange in a considerable number, instead of fair water you may make use of the water or milk of hemp, which is made after this manner:—Take a handful of hempseed, wash it well in spring water, then bruise it with a wooden pestle in another water, and press out the juice in a white linen cloth, and take it to moisten your composition. This is called hemp water or milk, and nourishes and warms your sick Canary birds better than fair water which is put to the common compositions; but it is not to be used unless in case of necessity, because it is troublesome to make such water twice a-day, and the little birds that are in health do not need to be much warmed as the hemp water does."

In speaking of the necessary materials with which the composition or paste is made the writer says—"As for provision of biscuits it is needless to lay-in any, because they are to be had at all times; but respecting the simnels a stock of them must be laid-in about Michaelmas, when the pastrycooks give over making of them. You must, therefore, cause several dozens of them to be made according to the number of Canary birds you have. String and keep them in a dry place and give some to your birds the day you give them no seed. They are very fond of it, and it can do them no harm. Brush the simnel well before you give it them because of the dust that may stick on it. The simnels I cause to be made have more crumb and are not so flat as the others. I cause good butter to be put into them, and a little more salt than is usual in others, and thus they keep very well till the time when new ones are made."

In the next chapter I will detail the several sorts of food Mr. Hervieux supplied his birds with when pairing, breeding, and when the young are caged.—GEO. J. BARNESBY.

### LESSONS FOR COTTAGERS.

MANY ladies and gentlemen have by letters asked me if what is called my system of bee-keeping could be put in little compass, so that they could easily and cheaply get the system into the hands and heads of the villagers and cottagers around them. The parties who thus wrote to me are greatly interested in the welfare of their poorer neighbours, and fancy that a few hives of bees well managed would help to uplift them above the difficulties of their present position. One cannot but admire the disinterestedness of those who are seeking to promote the comfort and social elevation of working people by putting them in possession of a perennial source of income and enjoyment.

From an experience extending over half a century of time, I can say that bees properly managed in rural districts yield a considerable amount of both pleasure and profit; and I hope—nay, I am certain, that as time rolls on and knowledge spreads, many classes of our working population who now waste much of their time and substance in public houses, bring poverty and misery upon themselves and their families, will alter their course of conduct and betake themselves to pursuits that are commendable, pleasure-giving, and self-rewarding. I know of nothing better, less toilsome, or more remunerating than a few swarms of bees. Yesterday a letter came from a collier in Staffordshire who has, he informs me, taken 90 lbs. of honey and six swarms from three hives, and he may get 90 lbs. more from his three first swarms. He readily sells his honey at 1s. 4d. per lb.

Though anxious enough to help cottagers and others who know little of bee-management, I do not believe that a very condensed treatise on their practical management would go far to accomplish what my friends wish. Very few of the cottage class of bee-keepers are seeking information. An example of success in their neighbourhood would awaken an interest. An object lesson or two would soon be copied, and the prospect of £ s. d. would deepen their interest and lead them on to success. I have seen many cases of this kind, and believe that they are now being multiplied very fast.

Though my book referred to is characterised by the plainness and simplicity of its lessons, I receive many letters from all classes asking for fuller information on this and that point, and many who well understand the meaning of the instruction given write for encouragement of assurance, that they, mere beginners, can carry it into practice.

The first lesson that English bee-keeping cottagers have to learn is this, that bees should have good houses to live-in, with

plenty of elbow room for work and expansion. Let them have an intelligent grasp of this idea, and one good season for honey after they have put the idea into shape, and all the rest will follow: they will get on and get up. I use and recommend hives made of straw, for I can find nothing equal to them for health, comfort, and convenience. All handy cottagers can if they like make good straw hives of any size, and those who cannot make or buy them will have to resort to boxes.

The question of the materials whereof hives are made is not so important as that of size. I have stated this more than once. Mr. M. Quinby, lately deceased, who was one of the greatest and most successful of American apiarists, took pleasure in stating that plain wooden boxes costing about 20 cents were as good for bees as more costly wooden patented hives. I fancy he was right, and if I could not obtain hives made of straw large in size I would use cheap unplanned wooden boxes. In large grocery establishments we find large empty boxes, suitable enough for bees, are sold at 2d. each. These would certainly be superior to the small straw hives so commonly used by English cottagers, inasmuch as bees would have more room in them. With boxes of this kind, containing from 2000 to 3000 cubic inches or more of space, any bee-keeper with a little experience might manage his apiary with success; and, moreover, with a very little ingenuity and modification the boxes could be used as supers, nadders, and ekes, or made to act-out the principle of Nutt's collateral hive and the Stewarton storifying one.

I am certain that when the poor bee-keepers of England come to know and realise the fruits of success from the use of large hives they will set a high value on their servants, and diligently work-out the details of any system of management they may adopt. And as we all believe in the "good, better, best," let us hope that working men and women may be led to adopt the system of management which puts most money into the pocket with the least possible trouble.

There are in the habits or natural history of bees some few things which should be understood by all who manage their bees intelligently. In every healthy hive of bees there are a queen or mother bee and workers which at one time were called neuters, because it was believed they were neither male nor female. But now it is well understood that they are female in character though they lay no eggs. They are produced and producible from the same kind of eggs as queens, but somehow, which nobody understands, they are dwarfed into infertility and are smaller than queens. Males or drones are bred in all hives about the swarming season.

A queen is fourteen days only in being hatched, leaves her hive when only a few days old to meet the drone, and never again leaves the hive but on swarming occasions. The queen lays all the eggs—is mother of the whole community—always goes with the first swarm and lives four years. After swarming and death she generally leaves princesses in royal cells, one of which will be enthroned in her place.

The working bees are three weeks in being hatched, and though they live nine months only, their history is full of marvels. They struggle into the world without assistance from any quarter, and finding themselves amid a scene of social, active life, they begin at once to push their way in the world. In less than three days they pick-up the acquaintance and companionship of thirty thousand fellow citizens, and know every one of them. Weather permitting they survey the country around, notice every prominent object within a radius of one mile or more from their hive, gather honey in forest and field, on hill-top and in valley, and never lose their way home. Their career from the cradle to the grave is one of untiring energy and disinterested service. Being loyal to a degree they will attend to their queen and meet her every want and wish; assist in setting her eggs, nurse and hatch all the brood, fetch all the water and bee-bread necessary, and as much honey as their strength permits them to carry and store away. They manufacture all the wax into combs after secreting it in their own bodies. The lives of bees are valuable—valuable for work in summer and for heat in winter.

I lately offered £7 10s. for 100 lbs. of condemned bees. If the offer is accepted the lives of 500,000 bees doomed to die by the fumes of sulphur will be saved. Let this fact be told in the cottage homes of England.—A. PETTIGREW.

### HONEY AT THE LAST CRYSTAL PALACE SHOW.

I HAVE no intention to use the pages of this Journal for any controversy with the Rev. C. N. Gray, but as he has herein reflected on the *bona fides* of the managers of the British Bee-keepers' Association I am impelled to reply. In lieu of Mr. Gray's honey being well packed it was simply not packed at all, although the supers were in large cases. After passing through the hands of several sets of railway servants it arrived as might have been expected—the greater part of it broken, and honey

running out. I, being Honorary Secretary at the time, wrote to Mr. Gray telling him the state, and he telegraphed to me to do the best I could, which I did. I have not noticed Mr. Gray's insinuation, nor two lawyer's letters from different legal gentlemen he has favoured me with, threatening me with all the terrors of the law unless I pay to him a sum of money more than the original value of his honey, and which he has already been paid for.—JOHN HUNTER, *Eaton Rise, Ealing.*

[We must decline inserting more on this subject.—Eds.]

### THE COMPLETION OF UNFINISHED SUPERS.

A LITTLE time ago it was maintained in our Journal that bees would not complete a super from a strange hive, but forthwith carry the contents below. It struck me at the time that Mr. Pettigrew had been misunderstood. At any rate, lest any young bee-keeper should be misled, allow me to say that I have removed several unfinished supers this season from one hive to another with a view to their completion, and have without exception succeeded. In no case were the contents carried below, but the bees took gladly to them and completed them.

Like everything else success depends upon the way in which the work is done. If an unfinished super is given to a strong stock—either a strong early swarm which has well finished and filled its hive, or to a non-swarm in a condition to occupy it—according to my experience the bees will set about completing it, provided that it be done during the honey harvest. I began this season with seven stocks on the non-swarming system. All but one swarmed and left several unfinished supers on my hands; yet, notwithstanding, all were completed save one, and this last only through the honey harvest coming to an end. One super was worked by three different stocks.

With the unfinished super I determined to test Mr. Pettigrew's suggestion of filling by feeding. The super was made to hold 20 lbs., and was not quite three parts full. Two of the combs were nearly finished and sealed, three others were in various states of progress. First I gave the refuse of some drained comb, next a bottle of run honey, and lastly some more refuse. It was all given on the top of the super. Not only did the bees proceed to fill the cells, but also to build fresh comb. The fresh comb was, however, of a dark brownish colour, and not such as we like to have in supers. I attribute this to the inferior material out of which the bees had to manufacture it.

Having satisfied myself that Mr. Pettigrew was right, if the thing was done in the right way, I gave it up; first because I had other things to attend to, and secondly because I found it would consume more honey than it was worth. For the satisfaction of your esteemed correspondent the "RENFREWSHIRE BEE-KEEPER," allow me to add that this super is not for sale, and that I quite agree with him in his view of the matter on that point.

Further, I have also had supers emptied and the honey carried below, but these were pieces of comb containing both honey and brood fixed in supers and given to weak stocks for that purpose. Stocks weakened by swarming will consume or carry down the contents of their own supers. In conclusion there are three rules to be observed:—1st, To give unfinished supers only to strong stocks in a condition to occupy them; 2nd, To do it at the right time—viz., during the honey harvest, not after it is over; 3rd, Carefully to fill-up any crevices at the juncture of the super and the stock hive with wedges of wood or strips of paper gummed or pasted.—O. B.

### THE STEWARTON HIVE AND SYSTEM.

YOUR correspondent "Q. B." is perfectly right—the Stewarton hive and system of bee-management gives a large amount of super honey with very little trouble. Combined swarms and non-swarming colonies are generally independent of all feeding, as their owner is of run honey.

The Stewarton hive is designed for non-swarming purposes. In its natal place swarms are purchased and brought from earlier districts on the coast, and combined to obtain the first and finest clover supers, wrought with 18 inches deep of breeding space, full-sized triple entrances, and carefully wrapped-up supers, in advance of their wants. Such colonies well shaded from the sun rarely swarm; with restricted space, if the bee-master wishes to increase his stock, they will, of course, give swarms as readily as any hive.

The advocacy of an indiscriminate large hive with fixed space, which can only be made yet larger with ekes, without the means of contraction, at the close of the season, to be employed in all seasons and districts, I regard as an absurdity. The Stewarton during the winter and early spring months possesses the advantage of being a comparatively small hive, standing in one or a couple of breeding boxes at most, where the heat is better concentrated and early breeding promoted with the advance of the season. It attains a depth of 18 inches, and an overflowing population to take possession of supers so soon as honey is

secreted in abundance, and becomes the largest of all hives, possessing facilities for supering and nadiring on *ad infinitum*; can be drawn out telescope fashion to focus exactly all seasons and districts, be they good or bad.

Boxes 12 inches deep would require cross sticks, rendering the combs fixtures; two 9-inch boxes make a better hive. My breeding boxes are 7 inches deep and every comb moveable.

The object of having supers but 4 inches deep, with bars 2 inches broad, is to obtain more massive and richer honey-combs, and the shallowness insures their more thorough completion. Such 20 lbs. supers are considered too large size for ready sale singly, each bar comb being removable with half-inch screws, and straight guide comb wrought increases the saleableness of boxes and their disposal without any cutting or waste. On young hives I generally use supers 3 inches deep to contain 15 lbs.

Placing the empty super upon the filling one instead of between it and the stock hive is in strict accordance with the habits of bees. They invariably store the honey for safety at the point farthest removed from the entrance in the stock hive—the top, brood to the floorboard: hence they elongate the brood combs in a downward, the honeycombs in an upward direction. This can easily be seen on the removal of a central bung from a common skep, when they at once proceed to build the comb upward through the aperture towards the roof of super; or, to illustrate further, take the case of the strongest colony in my apiary, stocked with first-class Italians the present season, I gave access to a couple of supers for a start. According to common opinion as laid down by your correspondent the bees would have begun work in the upper; but no, they started in the lower box, crowding up into the upper. By-and-by, finding them lying out badly, I supplied three more at once, and they were soon fully occupied. The lowest seen to be sealed-out was removed, still they threatened swarming, and it was not till after they had obtained the maximum of seven 4-inch supers did they settle down to determined earnest toil.

On my return home after a short absence on 18th August I made an examination of my several stocks. The colony above referred to, on the wrappings being removed, stood 4½ inches high from the floorboard, and peopled from top to bottom. On drawing the shutters I found the four lowest 20-lb. supers at the bottom of the pile thoroughly sealed out, fifth all but sealed, sixth combed out with thin combs, seventh about half combed. The four sealed ones I removed, which with the first harvested made five supers, leaving the remaining three uppermost on for completion in their respective order.—A RENFREWSHIRE BEE-KEEPER.

### THE BRITISH BEE-KEEPERS' ASSOCIATION.

THIS Association will hold their third annual Show at the Alexandra Palace on the 15th, 16th, and 18th inst., and considering the late brilliant honey harvest a fine show may be expected. Arrangements have been made to give practical lessons in bee manipulations during the meeting by Mr. Hunter, Mr. Cheshire, and others, for which purpose a large number of stocks are provided, after the use of which the Committee will be glad to supply at a nominal price to those amateurs who may be desirous of starting as bee-keepers.

### BEE MANAGEMENT.

I HAVE bought twenty swarms of bees at 1s. each, and I could buy one hundred more at the same price if I would take them up (drive them). They tell me that I shall not keep them alive all the winter, but I mean trying. One man tells me that he has kept bees for fifty years and that he knows no other plan than to brimstone them. Small straw hives only are used in this neighbourhood, but I have had some larger hives made, and when I get my swarms home I shall put two in a hive and feed them. All I want to know is this, Am I doing right or not? Is half a pound of syrup daily enough to keep the bees?—W. H. A.

[You have made a good bargain in buying twenty swarms for 20s., and you are doing right in putting two swarms together in hives larger than those in general use. But you must give each hive of bees 1 lb. of syrup every night for three days, afterwards 2 lbs. at least every night for a fortnight. Every hive should have 15 lbs. of sugar made into good syrup in fifteen days. From the syrup thus given your bees will build combs from top to bottom of the hives, and store food enough in them for the winter. You are now making a fair and promising beginning, and we wish you success.]

### NEW BOOK.

*Practical Bee-keeping. Illustrated, re-written, and enlarged by FRANK CHESHIRE, A.C.P.*

MR. CHESHIRE has long been known as an ardent and scientific apiarian, whose name in connection with various inventions

useful to the fraternity is no doubt well known to many readers of this Journal. Some of these inventions, which are most ingenious, have obtained prizes at the Crystal Palace Shows, and are in use in many if not in all modern high-class apiaries; for we must distinguish between apiaries the sole object of which is the acquisition of honey and those which combine this with scientific management. No doubt the primary *raison d'être* of an apiary is to obtain honey; and if this be the sole object of any bee-keeper we know no better guide or authority than our friend "on the paddle-box," the veteran Mr. Pettigrew, to whom to refer him. Big hives of straw and honey by the ton are and will ever be associated with his name. At a time when the tendency of our bee-keepers was to sacrifice utility and profit to the love of novelty and fancifulness Mr. Pettigrew came to the fore, and by dint of strong common sense showed how the old way and the old bees could hold their own and beat the modern fashions out of the field in the one respect alluded to above.

Granted, however, that such is the case, we are quite sure that at least as much honey can be obtained under the highly scientific treatment advocated by Mr. Cheshire, only it must be understood that no tyro can expect to be thus fortunate. The intelligent and skilful and experienced alone will succeed, and such as have time at their command. In their case—and there are multitudes of bee-keepers of this class—infinite pleasure and an interest inexhaustible will follow the adoption of the system advocated in this little book by Mr. Cheshire; for here are full and plain instructions to the amateur on every point connected with bee-culture, with carefully designed illustrations of the various materials used by the first apiarians of the day, including such items as bee hives of all sorts, improved feeding apparatus and processes, guide combs and how to make them, supers, bee and drone traps, transferring boards, queen cages, &c. The book closes with a complete calendar of operations during each month in the year, and last, not least, with a capital index.

We will only make one extract from Mr. Cheshire's book, and it shall be on the subject of the Italian or Ligurian bee, the merits of which in comparison with the dusky bee of our cottage gardens have been recently discussed in these pages. "We are of opinion," says Mr. Cheshire, "that the Ligurian is much more prolific than the black, and that it is ready for swarming earlier—advantages of no mean weight; but we have failed to note that greater strength of constitution in the foreigner which some assert." He adds in proof of the prolific character of this bee, although we are somewhat incredulous of the fact, that "the black bee hardly now exists; everywhere he has been improved by foreign blood. In 1874, in a most isolated moorland in Northumberland, where frame hives are unknown, but where little skeps abound, we failed to find a pure specimen of the English variety." Yet he observes "a lengthened observation of the two varieties is evidently needed before any conclusion can be arrived at" as to their relative value.

We recommend the book to the notice of amateurs.

## HONEY RECIPES.—No. 4.

(MEDICAL.)

TO CLARIFY HONEY.—Melt in a water bath and strain while hot through flannel previously moistened with warm water.

ALMOND AND HONEY PASTE FOR BEAUTIFYING THE SKIN, SUNBURNS, FRECKLES, &c.—Clarified honey 16 ozs., bitter almond powder 16 ozs. Rub smooth and add gradually in alternate portions 32 ozs. of oil of sweet almonds and the yolks of five eggs. Perfume with twelve drops of otto of roses.

HONEY PASTE (Pâte au Miel) FOR CHAPS, &c.—Clarified honey and cold cream equal parts rubbed smooth together.

HONEY AND BORAX FOR APHTHA (SORES) IN CHILDREN'S MOUTHS.—Dissolve 1 oz. of borax in 1 oz. of glycerine, and then add 6 ozs. of clarified honey.

HONEY GARGLE (Consumption Hospital Recipe for Consumptive Sore Throat).—Borax 1 drachm, honey 2 drachms, water 4 ozs. Mix.

OPHYMEL OF SQUILLS.—Vinegar of squills 5 ozs., clarified honey 8 ozs. Mix. Useful as an expectorant in coughs. Dose—half a teaspoonful four or five times a day.—JOHN HUNTER, *Ealing*.

FOREIGN POULTRY.—The value of poultry imported alive and dead this year was £113,216, against £131,587 in the corresponding period of last year.

## OUR LETTER BOX.

IPSWICH POULTRY SHOW (*Gertrude*).—An advertisement in our columns to-day announces that the old Show will be as usual. We know of no reason why both shows should not succeed if judiciously managed. Let us wait until we can observe the results.

EXTENSIVE POULTRY-KEEPING (*W. Illingworth*).—No one that we know succeeded in obtaining a living by keeping poultry. It has been tried by a

company, but epidemic diseases, unfavourable seasons, and low prices brought ruin. The further north the more unfavourable for poultry.

PIGEONS AT HALIFAX SHOW.—We omitted to mention in our report of the Halifax Show last week, that the five-guinea cup for the best pen in the Show was won by Mr. M. Hedley with his Black Carrier cock.

KILLING DRONES (*J. O.*).—No one can with certainty account for the drones in hives being permitted to live longer this year than in others. Some three or four years ago the drones in many prosperous healthy hives were not killed till October. In ordinary cases drones are killed in swarm hives about ten or twelve days after their queens begin laying. In parent hives, after swarming, and when their young queens have commenced breeding, the drones being useless are destroyed; then at the end of the season the general massacre takes place. Bees without queens, or with queens unfertilised, never kill their drones. Hives that do not kill their drones at the usual times should be examined, and if found without brood in their combs there is reason to suspect that their queens are either lost or useless.

PARROT MOULTING DELAYED (*A. K.*).—Warmth and extra nourishment are indispensable. You should alter the food thus, according to an authority on the subject:—"Hempseed and Indian corn given separately, each twice a week, bread and milk, with a few chillies cut small once a week. On the seed days a little saffron steeped in the water. If great difficulty in the moult, give captain's biscuits soaked, and made hot with cayenne, about three times a week, and put some liquorice in the water."

## REMARKS.

30th.—Dull morning, bright forenoon, dull afternoon, wet evening, and a windy night.

31st.—Damp morning; rather bright about 11 A.M., followed by rain soon after noon; showery day and wet night.

Sept. 1st.—A pleasant day; one or two showers during the day; a beautiful rainbow at 4.30 P.M.

2nd.—Fine, but rather hazy in morning, but soon fine; a pleasant day; slight rain between 4 and 5 P.M.

3rd.—Fine morning and pleasant day; but too cloudy from seven to nine for the eclipse of the moon to be seen here.

4th.—Pouring wet morning; alternate sunshine and showers during the day; rainy evening and windy night.

5th.—Windy all night, and heavy rain in early morning, but fine by 9 A.M., and a very pleasant day afterwards.

A great fall of rain, but little difference in temperature from last week, though some of the days seemed chilly.—G. J. SIMONS.

## COVENT GARDEN MARKET.—SEPTEMBER 6.

THERE are no quotable alterations in the prices of last week, and the tone of business remains in the same quiet state.

From observations taken near London during forty-three years, the average day temperature of the week is 68.0°; and its night temperature 45.5°.

## S ORING ROOTS FOR THE WINTER.

**T**HE storing of all kinds of roots cannot be too well attended to. Their perfect preservation depends entirely on how the work is done. Complaints of losing such and such a thing throughout the winter are not unfrequently heard; whereas most roots are quite as easily kept in their dormant state as in their growing one, but at the same time they should be just as carefully seen to at the one time as the other.

Roots requiring to be stored throughout the winter may be divided into two classes—namely, vegetable and flower roots. Amongst the former Potatoes are of the greatest importance. Sometimes these are stored in two different lots; the one for seed and the other for use. In either case the drying of the tubers is the first thing that must be done. External moisture in the slightest degree quickly causes decay when the tubers are laid together in a close place. An open shed is one of the best places for drying them when wet weather prevents their being exposed in the open air. They must be laid out thinly and should be turned over every day, or every other day at the furthest. When they are lifted out of the ground in dry weather little or no earth will be attached to them; but when lifted wet, as is sometimes necessary, much of the soil, especially if it is stiff, will adhere to them. This cannot be removed when it is damp so freely as when it is quite dry, so at first the roots should be spread out as they are lifted until they become somewhat dry, when they should be turned over and each of them rubbed with the hand to remove the soil. When the small tubers are separated for seed they should be laid aside at this time. After the tubers have become thoroughly dry there is no better way of preserving them than placing them in ridges in pits. The formation of the pit may soon be determined on. The spot on which it is to be made should be somewhat sheltered, and the ground must be quite smooth and clean; the bottom may be from 3 to 4 feet wide, the length being decided on according to the quantity there is to store.

Having decided on this, place a line along and notch out the shape of the pit with a spade. It is then ready for the Potatoes. They should not be laid close to the edge of the notch, but about 6 inches from it on each side. In a 3-foot-wide pit this allows a base for the tubers of 2 feet. From this width they must be built up in a triangular form to a sharp point or ridge. This work must be done on a sunny day. As the Potatoes are laid in a quantity of drawn straw should be at hand; a layer of this must be placed along each side against the Potatoes to the depth of 3 inches, and a crowning layer must be placed along the top. The straw should then be covered with 6 inches of soil from the sides. This should be dug out neatly so as to leave a trench along each side of the pit, and the surface of the pit itself should be beaten perfectly smooth and firm that all wet may pass into the side trenches freely. Sometimes a bunch of straw is

allowed to project here and there along the ridge with the intention of allowing vapour to escape; but these "straw chimneys" admit water, and probably do as much harm as good. In very severe weather it is often necessary to throw an extra covering of litter over the ridge. When stored early in autumn it is a good plan to open the pit once or twice throughout the winter, selecting a mild day for the purpose, and pitting afresh as soon as the Potatoes have been turned and the diseased tubers picked out. A sufficient quantity to serve for some weeks should be kept out, and as more are wanted they should be taken from one end of the pit, which should always be closed up as before as soon as they have been removed.

When Potatoes are retained throughout the winter in sheds or "Potato houses," a dry atmosphere must always be maintained, and the light must also be excluded. The temperature should never rise above 40°, as a higher heat induces the tubers to sprout, which must be guarded against.

Turnips may be kept in a perfect state of preservation in the same way as Potatoes. Carrots, Beetroot, Parsnips, Salsafy, and Scorzonera all require careful storing in winter. They may all be placed in one house, and under the same conditions. They should be dried after lifting, but not to an extent that will cause them to shrivel. They may be stored in a cool shed amongst sand; the latter should be moderately dry. A layer about 2 inches deep should first be spread along the bottom. A layer of roots must then be placed on this, when they should be covered with sand and another quantity of roots laid above this, and so on until the bin is formed. Too many should not be placed above each other—from eight to ten layers being sufficient. Wherever the slightest decay is suspected the whole should be turned over and the bad roots taken out. A high temperature causes the crowns to burst into growth; these growths should not be encouraged, but should be rubbed off at each turning.

Onions are always well worth looking after in winter. They are mostly ready for storing early in September. In dry weather they may be laid on the ground for a few days after they have been pulled up, turning them every dry day. In wet weather they should be spread out in an open shed, or some other place where air and sun can have access to them, but no wet. When the tops are dried up they are ready for storing in their winter quarters. They keep best in a cool dry loft or room of any kind where frost is entirely excluded. They may be spread out on the floor or shelves, or hung in nets. Sometimes they are strung together, and when this is the case they may be suspended from the roof. In whatever way they are stored they must be looked over frequently, as they are not exempt from decay.

Flower roots requiring to be stored during the winter are of a varied character. Perhaps the most common is the Dahlia. The stems of this plant should be cut off 2 or 3 inches from the root as soon as they are injured by frost or decayed. The roots must then be lifted with a fork, and covered over with dry hay or soil in the same place, or one similar to that in which the Onions are

stored. The roots are extremely tender, and a few degrees of frost will kill them. This must be strictly guarded against at all times. When Gladioli roots are lifted from the ground the stem when cut should be left about a foot long. The label of each one may be tied to the stem, and they may then be tied together in bunches of about a dozen and hung up in a dry room or shed; they may also be laid out on a shelf in the same kind of place.

Hollyhocks do not require so much protection. If planted in a cold frame when their stems are cut down, and covered up with sashes during severe weather, they will be found in excellent condition in spring. In sheltered situations they may be left outside altogether.

Referring to the more tender plants Caladiums are amongst the worst to deal with. They should not be ripened off too quickly. When the leaves begin to decay water should be given when needed until the roots are leafless. During this time and throughout the winter they cannot be safely preserved in a less heat than 55° or 60°. Underneath a stove stage or in a corner where heat is maintained is the place for wintering them. If the soil is moderately moist at the time the pots are stored away they will require no more water for some time, but the soil should never be allowed to become dust-dry, or the roots will shrivel and lose much of their vigour for the following season. Sometimes the bulbs are shaken out of the soil in which they have been growing and placed in sand throughout the winter, but when carefully looked after they keep quite as well in their pots. The same remarks apply to Gloxinias and Achimenes. The latter may be kept drier without injury in winter than most things. Gesneras may also be included as requiring the same treatment as these stove subjects. Many other roots might be named, but most of them survive the winter without any special treatment.—J. Muir.

### AUSTRALIAN GLADIOLI.

I SAW the other day in a contemporary a notice of what had been done in forcing the Gladiolus into bloom so as to give flowers in the months of February and March, and I should like to give my experience of what can be done with them in another way.

In the month of July, 1875, I received a courteous note from the Messrs. Lacy of Elizabeth Street, Melbourne, Australia, saying that they had forwarded to me a collection of twelve varieties of Gladioli of their own raising, which they believed to be equal to any of our European varieties, and asking me to try them, adding, "We hope that in 1877 you will be able to give us a good report of them. We have taken the standard prescribed in your book on the Gladiolus, and think the flowers are of good quality." A few days after I received the package through the politeness of the Messrs. Carter of Holborn, to whom it had been forwarded, and on opening it found thirty-six bulbs, some of which had already started some 2 or 3 inches. I immediately potted them singly in 32's and placed them out of doors, and was gratified to find in a few days that they were taking root and pushing away. I allowed them to remain until the end of September, when I placed them in my greenhouse. Here they grew until the end of February, when I dried them off. New bulbs had formed, but, as might have been expected, not of very large size—some about that of a shilling, and the largest about half a crown. In planting my beds in April I planted these small bulbs along with the others, hoping they might flower, and in this I was not disappointed; nay, more, so good were they that I exhibited two in the stand of twelve with which I gained the first prize at the Dover Show, beating my old rival and friend Mr. Edward Banks (not Baker) of Sholden. I thus managed to get two years out of one, and instead of being able to report on them in 1877 as Mr. Lacy expected, shall be able to do so in 1876.

Only a few of them have as yet flowered, but of some of these I can report very favourably. Sir Redmond Barry is a fine-looking spike of brilliant red colour with violet feathering. Rossini is of a most peculiar colour—a sort of velvety plum; I know of no Gladiolus quite like it. Venus is a grand-looking flower, white, very large and of great substance. Aurija, not so good. Katharina, a very fine-striped and mottled flower. The others have not yet flowered, and will come in with the Schillers, Beatrices, Sir John Franklins, and others of home-raising. There is one most desirable quality that these flowers possess—at the same time that the lowest flower opens the colours of the others show the whole way up, and in most of them I have had twelve flowers open at the same time, and

am very hopeful that another year when the bulbs have fair play that I may do even better with them.—D., Deal.

### EARLY APPLES.

"A NORTHERN GARDENER" has opened a subject, not only of interest but of utility, in his paper entitled "Early Apples." Since turning my special attention to pomology nothing has surprised me more than the indifference of so many owners and cultivators of gardens to the usefulness of Apples; not that they would not be willing to declare readily that the Apple is the most valuable of all hardy fruits, but they rest in this—are content with the trees they have, and do not by care and thought and culture make the Apple as useful as is possible. I leave out of consideration for the moment the great gardens, though my reasoning may apply even to them; but there are the little folks, the people with moderate incomes and moderate-sized gardens, and perchance orchards beyond the garden. Often useless trees are allowed to cumber the ground, or trees bought at a sale with no names, and which prove either indifferent sorts or more of one variety than are wanted. The extreme dryness and heat of the late summer and the scarcity of Apples, a scarcity caused partly by neglect in cultivation, may make gardeners more anxious to have a sufficient number of trees in future.

First, a word as to summer-eating Apples. The idea too general is that such are merely "school-boy fruit," and no doubt, as dealers well know, school boys, aye, and school girls too, are great and glad consumers of Juneatings, Early Harveys, and the like; but my experience goes to show that let early Apples of this character appear at dessert and dinner parties they are eaten. Later, when winter sets in, a dessert dish of eating Apples is scarcely touched, the same lot of fruit coming in day after day; then the Pear is preferred, the Apple being judged as hard and cold. Indeed, winter-eating Apples are not seldom chosen by their looks, as a dish of handsome Apples is very ornamental to a table, especially by candle light. Who has not seen and admired dishes of waxy, brilliant-complexioned Blenheim Oranges in a winter evening? but unless a group of children come in at dessert they are untouched. Not so the early eating Apples; let them only appear and be known to be ripe, they are relished extremely. A gardener at a great house will be deservedly popular in the school-room, the young ladies' room, and dining-room, who has a good supply ready of eating Apples during a hot July and August. This parching summer I see the papers have been recommending drinks made from Apples as both refreshing and harmless.

"A NORTHERN GARDENER" has specified and named three varieties—the Juneating, the Summer Golden Pippin, and the Devonshire Quarrenden. The first usually abundant in the smaller fruit shops, the second not generally seen, the last called in these parts the Sack Apple, grown everywhere in the west of England, and showing its rather tawdry cheek (it is not a refined-looking Apple) in every garden and orchard. These three need not be all. There is the Kerry Pippin, of pleasing regularity of form and good flavour, also very generally grown here, and well worthy of being planted everywhere. But the very best to my mind remains to be spoken of—the Irish Peach, better known in the east of England as the Early Crofton. Here we have an Apple fulfilling all the requirements of a dessert fruit. It is very beautiful, and has a flavour unsurpassed. What boy does not remember—if the tree were in his father's garden, or in some school-friend's father's (it's all the same to a boy)—the deliciousness on a hot August day of making his teeth meet in an Early Crofton, and the pleasant juice that gushed into his mouth? It was like eating and drinking all at once. And yet in hunting through each year at the fruit stand of a large and far-extending local show, I have only come upon one solitary dish of this beautiful and toothsome Apple; the Sack Apple, far its inferior in appearance and flavour, being everywhere. If the dryness of the past summer and the call for refreshing fruit result in planting more early Apple trees it will, I am sure, be well.

But there is another aspect of the early Apple question which demands attention. A very hot summer, such as the one we have recently passed through, causes the lesser fruits to be ripe all together. I had Gooseberries, Strawberries, Raspberries, and Currants, all ripe and over in a very short time. It was in vain to leave a portion of Gooseberries on the trees for later use, they simply dried up with the heat and became hard balls, the leaves at the same time dropping from the trees. What was to be done? Was the cook to open

the recently-closed jam pots? were preserves to be used which were prepared for winter's consumption? Here was August, aye, the end of July, and no fruit to use. Apple trees—the usual varieties—were not ready. I looked up at my Hawthorn-dens, they were not fit for use yet. I had the Worcester Pearmain, but it was only planted last autumn. How I wished I had been more provident years ago, and had planted some very early culinary Apples, as well as some very late sorts, towards which my prudential arrangements had tended.

I had written thus far when the postman, blessed man, specially on rainy Fridays (Journal-arriving mornings), brings my copy of "our J.," and there I read that capital article on useful Apples by "A MIDLAND FRUIT-GROWER."

Now, that said midland fruit-grower has by a proper retribution—a Nemesis will always arrive sooner or later—put me in the exact position I put a brother clergyman last winter. It was at a meeting to get the public-houses closed on Sundays. I spoke first and fully. My reverend brother came after, but he said I had made his speech. He meant to talk about the bottle in which the beer could be corked on Saturday night; he was going to mention "the comfort of the poor barmaids to take them from the atmosphere of stale beer and tobacco on a Sunday;" but I had done it, and so on, and so on, and so on. Now, "A MIDLAND FRUIT-GROWER" has served me in this cruel way. I had intended to speak of early culinary Apples, growing them dwarf and getting crops to pay us or please us, as the case may be, in a few years. Lord Suffield was to be mentioned, the Keswick Codlin also. The beauty of the Duchess of Oldenburgh was to have been glanced at, but 'tis all done by the "MIDLAND FRUIT-GROWER," who seems to have the power of knowing my intentions so far off. Is he a spiritualist? If so, what medium divined the inside of my mind? Well, I submit; I cannot help myself. My midland friend has written a capital paper, for am I not bound to think so as I was going to write just the same? However, jesting apart. Now that the subject of both early eating and cooking Apples is opened, perhaps the orchardist, amateur and otherwise, also any brother pyramid-growers, would give us their experiences as to the varieties of both kinds which they find to answer best. After the Hawthorndens (cropping by the way splendidly this year, though other sorts have failed grievously) it is easy to get a series until late winter and early spring; but what varieties are found ready earliest and of good flavour before the Hawthorndens are ready? What do growers of Early Julien say of that Apple, which has been strongly recommended to me by a great pomologist? What also of William's Favourite and of others? The point seems to be to get the very earliest and best.

"A MIDLAND FRUIT-GROWER" in alluding to "A NORTHERN GARDENER'S" article says, "He has confined his remarks to dessert kinds, and has mentioned a trio of undoubted value, omitting, however, in my opinion, other kinds at least equally good. It is not my intention to supplement the short list which he has given by enumerating other varieties of dessert Apples." Would he be so good as to alter his intention, and name the kinds in his mind? Then we should have a midland as well as a northern view of this matter.

Can anyone tell us the book name of the Apple called Domino? I see no such Apple mentioned in Dr. Hogg's grand book on the subject—the "Fruit Manual?"—WILTSHIRE RECTOR.

### TEA ROSE MARIE VAN HOUTTE.

No words can be too strong in describing the beauty of this Rose, particularly at this season of the year. Here (Dorsetshire) it grows like a weed, puts forth great shoots erect in growth, thick firm wood, and at the end of each shoot are four fine flowers, while down the stem of each strong shoot are many other blooms. I took a large shoot or spray of this Rose (which contained ten fine blooms and as many buds) to a dinner party, and presented it to the hostess.

The combination of colours in this Rose is the most delightful that can be imagined—pale primrose or lemon-edged, and shaded with peach. At a small exhibition at Lyme Regis I showed a stand of six Roses (the regulation number), and a more beautiful one I never staged. The six contained magnificent specimens of three splendid varieties of Teas: Souvenir d'Elise, Catherine Mermet, and Marie Van Houtte. These created quite a *furor*. I was asked by many, and entreated by some strangers, to sell them a plant, and to give them buds of Marie Van Houtte. My reply was, I cannot buy enough of her, I cannot find nurserymen who can supply large numbers of Tea

Roses. I do not know why it should be so, except that the Tea Roses give so few buds, and you often have almost to destroy a plant to obtain them. I think it would be a good thing to present a testimonial to the raiser who sent out this Rose. Can any of your readers say who is the raiser? I cannot find his name in any catalogue. It would be a way of showing the French raisers that we can appreciate a good Rose, and are willing to show our gratitude in a practical way.

How is it, by the way, that our English nurserymen never send out a new Tea? Mr. Keynes, it is true, has sent out a sport from Madame Willermoz, but this is not a new Tea, as Letty Coles stands in the same relation to Madame Willermoz as Eve did to Adam. I should not be surprised, however, if Mr. George Paul does soon send us one, as he is working hard to do so.

Catherine Mermet is very beautiful here in the autumn, more so I think than in the summer. The Teas scarcely recover from the spring frosts in time for the summer shows, but by the autumn have made fresh bloom-bearing wood. They then give me most charming blooms, and are most valuable for the late shows.—WYLD SAVAGE.

### OUR BORDER FLOWERS—MARSH MARIGOLD.

In early spring, when flowers begin to put in an appearance, we hail with delight in many of our moist meadows, and by most brooks, the Marsh Marigold unfolding its beautiful golden

Fig. 29.—*Caltha palustris*.

cup-like flowers. There is no more brilliant sight than acres almost covered with those charming spring flowers. Though mostly found in wet spongy places they do not object to pot and border culture. They are but a small family, but we seldom meet with any of them in cultivation; in some select collections we find *Caltha palustris* flore-pleno, which is a most useful variety for all purposes that flowers can be used for. I find this a useful pot plant for indoor decoration as well as the moist border; it is a plant that continues in bloom for a long time, and is invaluable for cut flowers and for bouquets, likewise for the moist rockery. *C. radicans* and *C. minor* are handsome plants, and are worthy of more extensive cultivation than they are receiving; they will bear a good deal of rough usage.

We have more kinds of this charming race of plants from America and other parts of the world. They

are increased by seed sown as soon as ripe, also by division of the roots in the spring after blooming. They require at all times a plentiful supply of water. *Caltha palustris* does us good service as an aquatic in a large pot or pan. When the bloom is past the plants can be put in some moist corner until they are again required.—VERITAS.

### EARLY ROSE POTATO.

VERY common has it been of late to abuse this American introduction in respect of its bad quality, but for dry soils and districts I know no more productive and excellent variety. I observe, too, that at the late Show at Sandy the Early Rose won first honours for its excellence when cooked, which is the proper way of judging Potatoes. I have Potatoes now of this variety which are of unsurpassable quality, and quite equal to others which were grown in the same field of Paterson's Victoria. Early Rose is also a prodigious cropper, and has ripened its tubers this year sufficiently early to be lifted before the rains, which have caused such extensive sapertuberation. I do not advocate the planting of Early Rose in rich and wet garden

ground, but in shallow soils in dry districts I regard it as one of the most profitable Potatoes that can be grown. So satisfied am I of its excellence that I should not hesitate to place properly cooked tubers in competition with those of any other variety, either of American or English origin. When the quality of Early Rose has been denounced I cannot but think that it has been grown in over-wet or over-rich soils, or the tubers have been imperfectly cooked.—A MARKET GROWER.

### AUTUMN PRUNING OF FRUIT TREES.

A SHORT time ago a suggestive letter appeared in your columns from Mr. W. Taylor on the desirability of the early winter pruning of fruit trees. It is no doubt wise to complete the pruning of fruit trees before Christmas, and in order that this may be done, and as further benefiting the trees, I would advise that the work be commenced in September.

One can scarcely visit a garden this year without being struck by two things—a scarcity of fruit and a superabundance of wood, especially on young trees—I allude now to orchard and pyramid trees of Apples, Pears, Plums, and Cherries. These trees having little or no fruit to exhaust or modify their strength have grown freely; their shoots are not only long but numerous, and must be considerably shortened and thinned during the winter months. But in the matter of thinning particularly, if it is necessary to remove the superfluous shoots in December, January, or February, it is, I urge, still more necessary to remove them now. If these shoots are not required for the permanent furnishing of the trees, why defer their removal to the dark days? It is a period of "dark days" now in the centres of many fruit trees, and surely by admitting light at a time when the foliage can benefit by it is preferable to admitting it when there is no foliage.

Further, by deferring the thinning of fruit trees to a time when they are denuded of their leaves it too often happens that the work is imperfectly done, and that after the thinning has been accomplished the branches yet remain too close and too numerous. It is all very well to say that gardeners can judge correctly in the winter season as to which shoots to cut out and which to leave in, and no doubt many can; but it is equally the fact that others err in leaving too much wood when they have not the foliage to aid them in forming a judgment of distances.

The real essence of pruning does not so much rest in a periodical shortening of the terminal branches of trees as in having those branches judiciously placed as to their distance from each other. If the branch of a fruit tree has sufficient space for the development of its foliage—that is, if its leaves can expand without touching the leaves on other branches—it matters little whether that branch grows to a length of 6 inches or 3 feet, it is almost sure to be in its nature and character a fruitful branch. Young branches of fruit trees which have full exposure to light and air are almost sure to form natural spurs, whereas if they are crowded they cannot do so; and no amount of shortening the branches in winter can render them fruitful, and even the thinning of them when long deferred is done too late to be effectual. The thinning of the branches of all kinds of fruit trees is a matter of prime importance, and if this work is properly done the question of shortening the extremities resolves itself into a simple matter of appearances—"putting the trees into shape."

If a practised man will now examine a vigorous-growing and crowded tree he will see at once that the branches are too numerous to remain as permanent fruit-bearers, and it is mentally resolved that the tree shall have "a good thinning" in the winter. But why not do the thinning now? Will the wounds heal less readily now than in winter? No. Can a better estimate be formed when there are no leaves to guide than when the foliage tells to a nicety when a tree is overcrowded? No. When overcrowding is visible, the evil being seen, can it be beneficial to suffer that evil to remain and increase? Surely no. Relieve, therefore, the overcrowded trees and relieve them at once. Let the foliage which is struggling for light, and by its efforts causing the darkness to be more dense, have light—life-giving, health-promoting, fruit-producing light. Light in winter when there are no leaves to absorb it is of little more benefit to a tree than are spectacles to a blind man. Afford aid, therefore, when aid can benefit.

Too often when thinning is deferred until the winter it is not half done. Thousands of trees tell us this in a way which cannot be mistaken. In the winter branches are removed and the tree looks thin, but wait until the foliage is expanded, and

the tree that "looked thin" in reality is thick, sealed alike against light and air—a banishment, as it were, of the elements which alone can promote fruitfulness.

The overcrowding of trees contributes more than anything else to the production of sappy and luxuriant branches. In desperate struggles for light branch competes with branch and leaf with leaf—both leaves and shoots increasing in size and numbers—struggling, as it were, to get out of the wood. Trees must and will have light, and if we do not guide the light to the leaves at one end of the branches they will stretch out and reach it by the other, and thus the elongation goes on which we call unnatural—unnatural growth. It is, however, really natural; nature, as it were, breaking through the rigid confines of art—the art of thick planting and pruning, which has resulted in the undue multiplication of branches.

It is not everyone who can correctly thin-out the branches of trees when they are leafless, but any intelligent person may thin them now, for he has the safe unerring aid of the foliage to guide him. Let him remove until the leaves on the remaining branches have room to expand, untouched by those of other branches, and admit the light to the very bases of the branches and centres of the trees. If this is done now the finishing touches at the winter pruning will be quickly given, and the trees will be in better condition than if their entire pruning were left to the leafless period—the "dark days" of winter.—A NORTHERN GARDENER.

### LESSONS OF THE SEASONS.—No. 4.

#### SPRING.

THE evils resulting from the excessive radiation of heat from glass structures have frequently excited my attention, especially at that season of the year when—

"Winter, lingering on the verge of spring,  
Retires reluctant, and from time to time  
Looks back; while at his keen and chilly breath  
Fair Flora sickens."

We erect buildings of glass and wood or metal, making them as light and airy as is compatible with strength, in order to throw as little shade as possible upon the interior, and to attract and transmit solar heat as readily as may be; they are, in fact, just so many "traps to catch a sunbeam," but unfortunately failing to keep it, or rather the heat arising from it, so long as is desirable, simply because it escapes, not so much through the crevices of the building as through the glass itself, which radiates heat so freely that a colder outside atmosphere invariably induces a chilling process, which on a clear frosty night acts with such rapidity as to render necessary a prompt and abundant supply of artificial heat to replace the waste arising in obedience to those natural laws by which the balance of Nature is maintained.

High wind is another cause of this loss of heat. The bitter north-east wind that was so violent and lasted so long in the early months of the present year swept with great force round every building, entering every crack and fissure, and playing upon the exterior with its icy breath—so cold, so cutting, and so keen as to render the maintenance of a steady interior heat a difficult and costly affair. We may suffer the temperature of a stove or vinery at work to fall 10° or 12° below its ordinary point on a stormy night without hurt to the plants or Vines, but when the wind continues to blow strongly and coldly week after week there is nothing for it but to throw in the fuel and stir up the fires—really to combat force with force, not but that such a contest is a thing to deplore, and which we would gladly avoid were it possible to do so, for no growth is equal to that upon which bright skies smile and soft fresh air plays. We cannot, however, reckon upon securing much of these great boons of Nature in early spring—the old dame's smiles are then too treacherous to be trusted; to-day the sun may shine and "the wind blow soft and fair," but the morrow's dawn may break upon a hurricane of snow and wind.

The early vinery in almost every garden has one end facing the east, the early house being put at the eastern end of a range in order that the Vines may derive as much benefit as possible from the sun; yet when the building is designed due weight is not often given to the fact that the east end is the most exposed to cold winds in spring—no attempt is made to introduce any special feature there to resist the sweep of the cold air which comes rushing against the building with great force, often at a critical period of the Vine's growth; but we find there the same materials and workmanship—good or bad, and, what is worse still, a door unguarded by screen or porch

of any sort. Imagine the effect of opening that door in a high wind, when there is a difference of 40° or 50° between the temperature outside and in the house! But even if the door is kept close at such a time there must still be a considerable amount of heat lost, not only through the crevices of the door and its frame, but also by the excessive radiation going on over the entire surface of that end of the vinery, all of which would cease if a glazed casing was attached to it sufficiently wide for the door to open, and with an outer door, not placed opposite the other, but in the front of the casing, so as to avoid cold draughts.

Before attempting to check radiation from the roof or any other part of a glass house it is important that we should thoroughly understand what radiation is, for if we fail to comprehend it we may end in something worse than a mere failure, and find ourselves promoting that which we designed to check. Simply stated, radiation is that throwing-off of heat which is constantly going on in all bodies or substances that are heated above the temperature of the surrounding atmosphere. To prevent this escape of radiated heat we have only to spread some thick substance, such as canvas or matting, upon a light framework slightly elevated above the building or body whence the heat proceeds, and we not only intercept it and check its radiation, but we envelope it in warm air. If, however, we suffer the covering screen to touch the heated substance or lie upon the building itself, it would, like the glass, simply absorb and radiate heat into the colder air. Whether a complete covering for a vinery is practicable or not I need not discuss here, my aim being rather to show how such a covering should be used, and the great benefit to be derived from it.—EDWARD LUCKHURST.

### TWELVE ROSES, ANY VARIETY.

THIS class is very generally neglected at our shows, and sometimes omitted from the schedule altogether. Often, when included, insignificant prizes are offered. On the other hand, there seems to be a growing tendency to offer prizes for twelve blooms of certain specified varieties, named beforehand in the schedule—e.g., twelve blooms of Duke of Edinburgh, twelve blooms of La France, &c., these classes being for the most part open and the prizes not high.

Now, firstly, when the schedule is formed it is quite uncertain whether the season will be a favourable one for this or that variety, so that these classes frequently produce no competition worthy of mention. I need hardly point out to exhibitors how different years are sure to be favourable to particular varieties and unfavourable to others. Secondly, I venture to think that few amateurs can make sure a week beforehand of staging twelve blooms of any specified variety, and the practice of entering for classes in which it is doubtful whether you will compete is certainly to be avoided.

On the other hand, most amateurs of any considerable pretensions could stage a creditable twelve of some variety when it comes to the point, and it not unfrequently happens that A or B may grow some less-known or weak-growing variety especially well. It is not very often that we see Edouard Morren shown at his best, yet at one of the shows this year I could have staged twenty-four blooms of that variety which would have surprised its depreciators. The reform that I would advocate is to abolish these classes for twelve blooms of Duke of Edinburgh, twelve blooms of La France, &c., and substitute two classes: 1, twenty-four blooms (any variety), nurserymen; 2, twelve blooms (any variety), amateurs. The prizes must be good, and there should be not less than four in each class. Exhibitors should be encouraged to stage more than one twenty-four or twelve if able to do so, and I would advise that they should be allowed to take as many prizes in the class as they can, of course for different varieties. I believe that these classes would be largely supported and greatly add to the attractions of our shows.—T. H. GOULD, *Mortimer*.

### THE CRYSTAL PALACE AUTUMN SHOW.

WHAT evil genius has presided over the preparation of the schedule of the Company, and what can be the motive of the Manager for putting it before the gardening public? Is it to display the poverty of the Company—to show how the mighty are fallen, and to degrade their Exhibitions into a mere provincial matter? Would it not be better, if they do not pay, to abandon them altogether? It is to be a three-days Exhibition, the last day being Saturday; no exhibits can be removed

until five o'clock on that day, and consequently to those from a distance it must involve remaining over Sunday. Mr. Coleman, for instance, of Eastnor in Herefordshire, who has been a regular exhibitor, cannot possibly reach home that night. And what do they offer for a collection of fruit of ten dishes, which will include Grapes, Peaches, Nectarines, and Figs, all perishable fruit? £5! and not one dish would be fit to put upon the employer's table when they return home, nor fit to send to Covent Garden for sale except at a ruinous loss. Turning to flowers I find £2 offered for forty-eight Dahlias, and £3 for thirty-six Gladioli. Is it likely that any but third-class exhibitors will be found with such prizes? It is possibly too late now to alter, but I am not surprised to find that many of their supporters decline accepting their munificent offers, and I fancy there are many who, like myself, will sign themselves—A FORMER EXHIBITOR.

### JUDGING VEGETABLES.

WE cannot attend two horticultural exhibitions in town or country where vegetables are a special feature without being struck by the different tastes and prejudices of those who award the prizes, and seeing what a lottery the whole affair is with exhibitors. Even in the same show-ground, at times where there are different judges for separate sections, great contradictions may be witnessed. A dish of vegetables may pass unnoticed in the cottagers' section, which had it been exhibited by an amateur might have unanimously received a first prize, and *vice versa*; also the kind of produce favoured one season may be thought much less of another season when a different set of judges are officiating. Now I do not maintain that cottagers' produce should be judged by exactly the same standard as that of gentlemen amateurs. With the latter quality should be the only test, but in judging the former a little leaning should be made towards those sorts of vegetables and that mode of culture which produce a great quantity. I do not mean to encourage coarse-growing vegetables and altogether ignore quality, there is already too much of that, but for a poor man there is no reason why he should be taught to gather his Peas when only half grown, or Vegetable Marrows when only as thick as his wrist. Both of these vegetables are quite as good to his palate when grown larger, and are far more economical. But there ought to be more consistency and agreement between different exhibitions and different judges. A man when exhibiting in any class ought to be able to form an idea of the kind of produce which will be favoured or otherwise. The exhibitions defeat their own aims. A practised hand can do this to a certain extent with fruit and flowers, because there are recognised standards of excellence amongst judges, and also, perhaps, there is more caution exercised in selecting the judges. Almost every lady and gentleman knows, or at least they think they know, something about judging fruit and flowers, and therefore they know something of the difficulties the judges have to contend with; but judging fruit and flowers is child's play compared with judging vegetables when it is done carefully and honestly, and good judges of such things are extremely few, whilst those who may be called good judges hold very different views, and there is anything but consistency in their awards.

It is, therefore, with the view of ventilating the subject, and the desire of coming to some agreement as to the way in which vegetables should be judged, that I pen these remarks. Generally, I believe, outward appearances count for too much. In my own practice I use the knife unsparingly, and I maintain that nobody can judge correctly such things as Beetroot, Celery, Potatoes, Turnips, or Vegetable Marrows without it, and when a decision has to be made on very fine points I would use it for several other vegetables. There is not so much difficulty with collections of vegetables when limited to a certain number of sorts, as they always should be, but it is when Carrots are shown against Carrots, Celery against Celery, &c., with, perhaps, twenty dishes so much alike that to the general public there is not a pin to choose, and the judges themselves are sorely puzzled, that the knife comes to the rescue, and very soon brings the really good within narrow limits. Having decided to use the knife, we next come to consider the points of excellence or otherwise revealed by it, for things are now altogether changed. Those very fine heads of Celery which everybody declared to be perfect are seen to have bolted half way up; that pair of nicely matched, beautifully shaped Vegetable Marrows is found to be all seeds, and the woolly material or the flesh is extremely coarse; Potatoes so even in size, and

with scarcely a visible eye, are found to be yellow in flesh, and, perhaps, overgrown and black in the centre.

Outward appearance is very commendable, and when judging flowers it should receive every encouragement, but we must remember that vegetables are grown to be eaten, and should be judged accordingly. We want good appearance, but we must not have it at the expense of quality. Our Warminster friends through the shrewdness and liberality of Mr. Joseph Smith have come to acknowledge this, so far as the most popular vegetable is concerned, and offer prizes for the best dishes of cooked Potatoes, and a most interesting class it is; the difference in the appearance of the different dishes is marvellous, and there is no difficulty in awarding the prizes.—WM. TAYLOR.

## DUNDEE INTERNATIONAL HORTICULTURAL EXHIBITION.

SEPTEMBER 7TH, 8TH, AND 9TH.

INTERNATIONAL horticultural shows have become quite common in Scotland of late years, but hitherto they have been confined to Edinburgh and Glasgow. This is the first time that an "international" has been held further north than either of these cities. Dundee is only second to Glasgow for commerce in Scotland, and the inhabitants number close upon 150,000. Proceeding to it *via* Stirling and Perth the scenery is exceedingly picturesque, especially when passing through the Carse of Gowrie, where the ground is well adapted for high-class farming and fruit-growing. Apples, Pears, and such-like fruit appear to be a much more abundant crop there than in the south.

Dundee has long been celebrated for the excellency of its autumn shows, but the very best of their former exhibitions was entirely eclipsed on this occasion. As was stated at p. 194 prizes were offered amounting to about £1000. The classes numbered 206, and there were 2927 entries. Two very large halls and an extensive marquee could barely contain the immense number of exhibits, and so far as the various horticultural productions were concerned the Exhibition was quite a success, but the arrangement of the Committee was far from encouraging. It was late before many of the Judges arrived on Wednesday night, and no arrangement whatever had been made for their accommodation. Each one was told to find shelter where he liked. Any exhibitor who wanted to see his products next morning had to pay 5s. for admittance. Even nurserymen from London, to whom the Committee were greatly indebted for the success of their Show, were treated in this short-sighted manner. At Edinburgh and Glasgow the Judges were always accommodated together, and all gardeners had the appreciated privilege of seeing the Show at a very cheap rate before the public were admitted, but no such liberality characterised the Dundee gathering. The luncheon tickets were 15s. each, which placed what might have been a sociable meeting to many gardeners quite beyond the reach of ordinary people. No doubt this is a paying way of doing things at present, but on a future occasion it is more than probable that it will be found to be a penny-wise-and-pound-foolish system.

That munificent patron of horticulture, the Earl of Strathmore, Glamis Castle, opened the proceedings with a speech, in which he remarked that the wish he expressed two years ago to have an international show in Dundee had been speedily realised. They had disadvantages in the northern climes which southern competitors had no cause to complain of, and it was overcoming these disadvantages which had made Scottish gardeners so successful and distinguished in their profession. He hoped the Show would be the means of increasing in many the desire to encourage horticulture, as he thought there was no science more worthy to be encouraged than this.

It may be stated that the Show was not equal to other shows which have been held in Scotland. Comparison was rife, and locally it was asserted to be the best exhibition that had ever been seen in the kingdom, but this was not the case. Taking the Grapes altogether, they were inferior to what was at any of the Edinburgh Internationals, and collections of fruit and Pines were not so numerous as at previous exhibitions.

**COLLECTIONS OF FRUIT.**—For the twenty varieties there were only three competitors. The first prize (£15) and a gold cup valued at £20, presented by the Earl of Strathmore, was won by the Earl's own gardener, Mr. Johnston, Glamis Castle. His Grapes were superb, and consisted of Muscat of Alexandria; a neat bunch, very large in berry, of Madresfield Court; Lady Downe's, fine; Buckland Sweetwater, which is always shown in grand condition from Glamis; excellent Black Hamburgs; two small but well-formed and ripened Smooth Cayenne Pine Apples; Lord Strathmore and Meredith's Hybrid Cashmere Melons; Elruge, Duc de Telliers, and Pitmaston Orange Nectarines; Gros Mignonne and Red Magdalen Peaches; Jargonelle Pears; Morello Cherries; Victoria, Jefferson's, and Green Gage Plums; Shipley's Apricots, and Stirling Castle Apples. The strongest part of this collection was the Grapes.

Peaches and Nectarines were not of the largest size, but were finely coloured. Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, who is a young exhibitor of considerable promise, was second. His collection was composed of excellent Canon Hall Muscats, Madresfield Court, Foster's White Seedling, Black Hamburgs, and Muscat of Alexandria Grapes; one Smooth Cayenne and one Queen Pine Apple, a Victory of Bath (green-flesh), and a Hero of Bath (scarlet-flesh) Melons; Violette Hâtive and Princess of Wales Peaches; Victoria and Violette Hâtive Nectarines; Moor Park Apricots, Morello Cherries, Imperial Gage and Jefferson's Plums, Jargonelle Pears, and Brown Turkey Figs. The Grapes here were inferior to the first, but many of the other fruits were equally good. The third prize was awarded to Mr. Donald Matheson, Meikleour, Perth, for a collection in which there were some very good Foster's Seedling, Black Hamburg, fine Black Alicante, Muscat of Alexandria and Lady Downe's Grapes; small Queen Pine Apples, Golden Perfection and Emerald Isle Melons, Jefferson's and Kirk's Plums; Rivers's crimson Galande, Belle Beaunce, and Noblesse Peaches, Elruge and Violet Masqué Nectarines, Moor Park Apricots, White Marseilles Figs, and Louise Bonne of Jersey and Beurré d'Amanlis Pears. Some considered this collection equal to the second, but many of the small fruits were not perfectly ripe. Owing to Mr. Johnston carrying off the cup, the Earl of Strathmore decided on presenting Mr. Goodacre with one of equal value. It is to be regretted that there was not more competition for the handsome prizes offered in this class.

For the collection of fifteen sorts of fruit, Mr. Upjohn, gardener to Lord Ellesmere, Worsley Hall, Manchester, was easily first. His Grapes were not large in bunch but were finely finished. The Gros Colmans in this collection were the best of this variety in the hall, and the only bunches of Waltham Cross which were exhibited were staged here. They were barely ripe, but the berries were well swelled and very equal in size. The Black Hamburg and Muscat of Alexandria Grapes were also good, and the remainder of the collection was composed of Queen Emma and Methven's Early Gem Melons, Hardwick's Seedling Nectarines, Bellegarde and Violette Hâtive Peaches, Guthrie's Late Green and Kirk's Plums, Fondante d'Automne Pears, and Golden Pippin Apples. This was a first-rate collection. Mr. McDonald, gardener to J. Paterson, Esq., Kinnettles, Forfar, came second. The Smooth and Queen Pine Apples were not large, but the Black Alicante Grapes were well finished, and Royal George Peaches were also in good condition. Mr. John Thomson, gardener to the Right Hon. Lord Rollo and Dunning, Duncrub, Perth, was third.

Mr. Dickson, gardener to J. Whyte-Melville, Esq., Mount Melville, St. Andrew's, Fife, was first for ten varieties of fruit. Golden Champion and Duke of Buccleuch were well represented here. The former was as near free from spot or blemish as possible. The Barrington and Noblesse Peaches were also fine, but Oranges constituted a dish that might have been replaced with advantage by some other fruit. The second prize was awarded to Mr. McConochie, gardener to A. Smollet, Esq., Cameron House, Dumbarton. The Grapes were excellent in this collection. A finely coloured bunch named Muscat of Alexandria had a greater resemblance to Buckland Sweetwater than anything else. The Lady Downe's were well finished; and a Melon, the Colston Basset variety, was an excellent fruit. Mr. D. Ross, St. Martin's Abbey, Perth, was third, his Black Hamburgs being well coloured but small in berry. The Noblesse Peaches were the best amongst the stone fruit, and the Golden Perfection and Reed's Hybrid Melons were fair samples. For the collection of eight varieties of hardy fruit Mr. Fairgrieve, gardener to the Dowager Duchess of Athol, Dunkeld, was first; Mr. A. Stewart, Glendrick, second; and Mr. McDonald, Kinfauns, third. Victoria, Kirk's, Jefferson's, and Golden Drop Plums were conspicuous in all these collections.

**GRAPES.**—There was an immense quantity of Grapes shown. As at previous Internationals the eight-variety class, one bunch for each, was the great centre of attraction. The first prize for these was £15 and a gold medal (£5). Here again Mr. Johnston of Glamis secured the first place. His bunches were even superior to those he had in the collection of twenty sorts. One of the most perfectly finished bunches of Black Hamburgs that has ever been exhibited was in this lot. The bunch was not so extraordinarily large, but the berries were splendid, and not a speck of anything had disturbed the bloom. The other varieties were Lady Downe's, Chasselas Napoleon, Royal Vineyard (a sort not often cultivated), Madresfield Court (extra good), Muscat of Alexandria, Burchard's Prince, and Black Alicante. There was not the slightest perception of decline from Mr. Johnston's previous high standing in one of these bunches. Mr. Hunter, gardener to the Earl of Durham, Lambton Castle, was placed second. His varieties were Calabrian Raisin, Black Alicante, Burchard's Prince, White Tokay, Black Hamburg, Barbarossa, Muscat of Alexandria, and Trebbiano. Every one of these bunches was of the same enormous size that Mr. Hunter has always been in the habit of showing. They only lacked one important particular, and that was colour. Another fortnight

or three weeks would have placed them in a different position. Mr. Reid, gardener to A. H. Moncur, Esq., Rockfield, Dundee, came third with small well-finished bunches of Gros Colman, Lady Downe's, Muscat Hamburg, very fine; Buckland's Sweet-water, Black Hamburg, Muscat of Alexandria, and the worst ripened bunch amongst the lot, a greenish Mrs. Pince. Mr. G. Kidd, Megginch, Errol, was competing for the eight sorts and received an extra prize of merit, having some good Black Hamburgs, Lady Downe's, Muscat Hamburg, and the finest developed bunch in the Show of Buccleuch.

Mr. P. Stewart, gardener to Charles Tennant, Esq., The Glen, Peebleshire, had no difficulty in securing the first prize for four sorts of Grapes. Good fruit is always expected from Mr. Stewart, and we were never further from being disappointed than on the present occasion. His four bunches—Mrs. Pince, Muscat of Alexandria, Black Hamburg, and Trebbiano—were rare examples of good culture. Mr. A. Bruce, gardener to J. Field, Esq., Chorlton-cum-Hardy, Manchester, who is a regular exhibitor at the Internationals, was second. His bunch of Bowood Muscat was excellent, and so was his Duke of Buccleuch, Barbarossa, and Madresfield Court. The third prize was awarded to Mr. Kettles, gardener to Lady Mary C. N. Hamilton, Archerfield, with a good bunch of Muscat of Alexandria, Gros Colman not well coloured, a fair bunch of Barbarossa (Gros Guillaume), and another of Black Alicante.

Mr. Johnston, Glamis, was first for two bunches of Black Hamburgs. These were a splendid pair, nearly equal to the one referred to in the eight varieties. Mr. Stewart was second with a pair very little inferior to the first, and Mr. Dickson was third.

For two bunches of Muscat Hamburg Mr. D. Fowler, gardener to P. Swan, Esq., Cupar Fife, came first with good-sized bunches but small in berry, and in these, as well as in the second-prize two from Mr. Morrison, the colour was deficient.

Mr. Bruce was first for two bunches of Madresfield Court, and Mr. W. Watson, gardener to A. Gilroy, Esq., Dunalstair, second with fine-formed bunches. There is no doubt Madresfield Court is a grand variety for exhibiting if it is cut immediately it is ripe.

Mr. Hammond, gardener to Sir Wilfred Lawson, Brayton Castle, Carlisle, secured the first place for two bunches of Black Alicantes, with the finest samples of this variety in the Show. They were jet black and finely covered with bloom. Mr. Maul, Renfrew, was second; and Mr. Goodal, gardener to Mrs. Raffin, Houisa House, Edinburgh, third.

For two bunches of Lady Downe's, Mr. Johnston was first with fruit showing a shade of green about the footstalk. Mr. Steel, Dundee, came second; and Mr. Morrison third. For the same number of Mrs. Pince Mr. Bruce was placed first, Mr. Stewart second, and Mr. Reid third.

The next prize is a rather important one, being for two bunches of Muscat of Alexandria. In this Mr. Stewart came in before Mr. Johnston with two grand-shaped and developed bunches, just a shade greener than the first.

For two bunches of the Duke of Buccleuch, which was exhibited in many parts of the hall, Mr. Ballantyne, gardener to J. T. Smith, Esq., Duloch House, Inverkeithing, Fife, has been awarded first. His bunches were large and clean, and not quite so green as the second-prize two from Mr. Dickson, St. Andrew's.

For two bunches of any sort of white Grape Mr. Goodacre came first with splendid Golden Champion; Mr. Hunter being second with two fine bunches of Foster's Seedling; and Mr. Greig, gardener to R. Christie, Esq., Craigend Park, Edinburgh, third with Chasselas Napoleon.

For single bunches of Grapes Mr. Steel was first for Black Hamburg, and the same for Black Alicante; Mr. Bruce being first for Lady Downe's; and Mr. W. Goldie, gardener to R. Kerr, Esq., Irochragna, had the same position for Barbarossa. For one bunch of Golden Champion some excellent bunches were shown by Mr. Dickson, Mount Melville, Mr. Bruce, and Mr. Greig.

The large bunches have degenerated considerably from what they were last year. In fact, the "champions" had a narrow escape of securing an "ex" to their designation; there only being 2 ozs. between the Barbarossa bunch of Mr. J. Dickson, Arkleton, and the one of the same variety from Mr. Hammond of Brayton Castle; their bunches weighing 10 lbs. 2 ozs., and 10 lbs. The heaviest white came from Mr. Carron, gardener to G. Douglas, Esq., Eskbank, who exhibited a bunch of Trebbiano 16 lbs. 2 ozs., while Mr. Dickson was second with a White Nice exactly 2 lbs. lighter. None of these "big bunches" were ripe.

There was one or two seedling Grapes sent for the opinion of the Judges, but none of them was considered worthy of notice.

**PINES.**—These would number about a score. Some of them were not half ripe, others half rotten. Mr. Goodacre was first for two Queens, his fruit being good although rather short. They would weigh about 3½ lbs. Mr. Kettles, Archerfield, was second. One of his fruit was over 5 lbs., but the other one was not quite so good and somewhat green. Mr. A. Jamieson, gar-

dener to the Earl of Crawford, Haigh Hall, Wigan, was awarded first for two Smooth-leaved Cayennes with somewhat small but well-shaped fruit.

In the class for weight Mr. Peacock, gardener to J. Bruce, Esq., Castledykes, Dumfries, was first with a Providence, said to weigh 11 lbs. 2 ozs. It was much disfigured through having a number of crowns. Mr. G. Wyness, Usan House, Montrose, was second with a finely grown Queen, which would weigh upwards of 6 lbs. These are all that are worth mentioning. This department of the Show was not a great success.

**MELONS.**—These were largely shown, some beautifully netted fruit being amongst them. Very few of them were named. In the green-flesh section Mr. Farquhar, gardener to Colonel Gordon, Fyvie Castle, Aberdeen, was first with a variety named Haddo House, Mr. McConochie being second, and Mr. Bowman, gardener to Lord Deas, third with Princess Alexandra. Mr. Farquhar was also first for the scarlet-flesh with a fine fruit of Little Heath, and Mr. Montgomery, gardener to the Earl of Breadalbane, Taymouth Castle, was second.

**PEACHES, NECTARINES, AND APRICOTS.**—Peaches were a fair show, but the fruit was not all of a first-class kind. For twelve fruit in two varieties Mr. W. Brown, Kilmarnock Castle, was first; Mr. J. Leyden, Rosewell, Edinburgh, second; and Mr. J. Combe, Glencarse, third. For six Mr. Dickson, St. Andrews, came first, and Mr. Halliday, gardener to the Earl of Mansfield, second. The varieties were chiefly Barrington, Royal George, Noblesse, and Salway.

Nectarines were numerous and an excellent show. Mr. D. Fowler was first for the twelve; Mr. Methven, gardener to Col. Campbell, Blytheswood, being second; and Mr. D. Lamond, Arthursstone, Meigle, Forfar, third. In the class of six Mr. Fowler was placed first; Mr. Macdonald, Kilfauns, second; and Mr. J. Loudon, Chirk, Salop, third. The sorts were mostly Elruge and Pitmaston Orange. Mr. Kidd was first for twelve Apricots, Mr. Methven second, and Mr. McDonald third. Moorpark was the leading variety.

**APPLES, PEARS, AND PLUMS.**—Apples made the finest display in this section. For a collection of twenty sorts Mr. Kidd was first with an excellent assortment, among which we noticed some fine fruit of Irish Peach, Small's Admirable, Cox's Orange Pippin, Duchess of Oldenburgh, New Hawthornden, Lord Suffield, Tower of Glamis, Ribston Pippin, and Stirling Castle. Mr. Mathew was second. In his collection the following were of more than ordinary merit—White Codlin, Warner's King, Lady Johnston, Pent Stoup, and Blenheim Orange. Mr. G. Edgar, Crossgar, Co. Down, came third; Nonpareil, Early Almond, Golden Noble, and Nelson's Glory being noteworthy. In six Apples for weight Mr. Grey, gardener to Sir J. A. Cathcart, Killochan, Ayr, was first with very large fruit of Lord Suffield. This fine variety was extensively shown.

Pears excepting Jargonelles were poor. Mrs. Gellender, Denton, Newcastle, was first for twenty sorts; and Mr. J. Cairns, gardener to the Earl of Home, Hirsell, Coldstream, was first for the six heaviest fruit.

Plums were staged in good order. For three varieties, four of each, Mr. Fairgrieve was first, Mr. McDonald second, and Mr. McConochie third. The sorts were Jefferson's, Victoria, Kirk's, Coe's Golden Drop, and Washington.

There were some fair dishes of Castle Kennedy, Brown Turkey and other Figs. For these Mr. Halliday was first; Mr. W. Milne, Woodhouse, Leicester, second; and Mr. Bruce, Manchester, third.

**PLANTS.**—The collections formed by far the most attractive feature in the Show. The group from Messrs. Veitch & Sons, Royal Exotic Nurseries, Chelsea, London, filled a wide side stage about 40 feet in length along the side of the principal hall. A more splendid collection of new, rare, and beautiful plants was never witnessed in Scotland. They were arranged in a most artistic manner, and the whole was as near perfection as could possibly be imagined. The Nepenthes were such as Messrs. Veitch alone can show. *N. Hookerii*, *N. Chelsonii*, *N. hybrida*, *N. Sedeni*, *N. Rafflesiana*, and many others were entirely surrounded with fine pitchers, and their size, especially of the last-named, was most remarkable. *Croton Mooreana*, *C. majesticum*, *C. Youngii*, *Oncidium concolor*, a well-bloomed *Cattleya elegans*, *Ixora Dixiana*, *Lapageria alba*, *Anthurium Veitchii*, *Oncidium tigrinum*, *Cypripedium Sedeni*, one of the finest plants in the country of *Croton Disraeli*, *Odontoglossum bictonense roseum*, with nine flower spikes; *Phyllanthus roseum pictum*, and *Odontoglossum Insleyii leopardinum* are only a few of the many splendid plants in this fine group.

The collection from Mr. B. S. Williams, Victoria and Paradise Nurseries, Holloway, London, occupied the same position on the opposite side of the hall. There were many excellent plants here, several of them being much larger than in Messrs. Veitch's group. Mr. Williams is well known as an exhibitor at all horticultural gatherings of note, and his plants in the present instance were quite up to their usual high-class order. Particularly noticeable in this collection were some excellent specimens of *Dracena Baptisii*, *D. Hendersonii*, *Ixora floribunda nana*, the

white-spathed *Anthurium*, *Croton majesticum*, *C. pictum*, *Araucaria robusta glauca*, *Reidia glaucescens*, *Nepenthes Dominiana*, *N. Rafflesiana*, *N. intermedia*, *N. ampullacea*, *Gleichenia Mendelii*, *Adiantum amabile*, *Nerine Fothergillii major*, *Darlingtonia californica*, *Allamanda grandiflora*, *Demonocrops palembanicus*, *Alsophila australis Williamsii*, &c.

Messrs. Ireland & Thomson, Craigleith Nurseries, Comely Bank, Edinburgh, had a group of small but exceedingly healthy and excellently-grown stove plants. Amongst these there was a grand plant of one of the finest of Palms, *Geonoma gracilis*, a good *Cocos Weddelliana*, *Aralia Veitchii*, *Dracæna Taylori*, *D. hybrida*, *D. elegantissima*, *Croton Disraeli*, *C. Mooreana*, *Begonia Acme*, *B. Kallata*, *Adiantum gracillimum*, *Artocarpus laciniatus metallicus*, the beautiful light Fern *Nephrolepis davallioides furcans*, &c. This select group showed more of the first-class London style of exhibiting than we are accustomed seeing in Scotland, and it was highly creditable to this "young firm" of exhibitors. A very fine collection of choice Conifers came from W. Barron & Son, Elvaston Nurseries, Derby.

NEW PLANTS.—For twelve plants not yet in commerce Mr. W. Bull, new plant merchant, London, was first with some beautiful plants, the finest of which were *Croton gloriosa*, *C. Cheloni*, *C. princeps*, *Dieffenbachia amœna*, *Curmeria Wallisii*, *Zamia princeps*, *Dracæna Goldieana*, *Sadleria cyathoides*, *Philodendron Boltoni*, and *Catakidozamia nobilis*. Mr. B. S. Williams was second; in his group being *Croton Queen Victoria*, *C. Williamsii*, *Adiantum digitatum*, very attractive; *Maranta Henryii*, *Davallia Youngii*, *Kentia Mooreana*, *Araucaria Goldieana*, and *Platynerium Wallickii*. Messrs. J. & R. Thyne, Glasgow, were third; the best amongst theirs being a new *Todea*, a dark-leaved *Betris Baronii*, and *Aralia caledoniana*.

STOVE AND GREENHOUSE PLANTS.—For twenty plants Messrs. J. & R. Thyne were first with some excellent plants of *Cycas revoluta*, *Cocos Weddelliana*, *Croton Youngii*, *Dracæna Baptistii*, *D. Veitchii*, *D. Sheppardii* (a grand plant), *Allamanda Wardleyana*, *Erica Marnockiana*, *Maranta zebrina*, *Rhynchospermum jasmynoides*, *Eucharis amazonica*, &c. John Stewart & Sons, Broughty Ferry, Dundee, were second; and James Cocker and Sons, Sunny Bank Nurseries, Aberdeen, third.

Messrs. J. & R. Thyne were first with ten exotic Ferns; two of the best plants being *Adiantum farleyense* and *A. acuminata*. *Clematis* were poorly shown, but the plants for dinner-table decoration were excellent. They were arranged in a row along the centre of both the long fruit tables. In the nurserymen's class for twelve plants Messrs. J. & R. Thyne were first, their plants being *Croton Disraeli*, *C. hybrida*, *Geonoma gracilis*, *Pandanus Veitchii*, *P. elegantissima*, *Dracæna gracilis*, *D. terminalis*, *Aralia leptophylla*, *A. caledoniana*, *Reidia glaucescens*, *Panax excelsa*; Mr. Wm. Paul, Crossflat Nurseries, Paisley, being second; and Mr. J. Sutherland, Lenzie, Glasgow, third. There were many entries in this class, and the plants were all in 6-inch pots and from 12 to 18 inches high.

The principal plant prize in the gardeners' class was for twelve stove and greenhouse plants. In this Mr. H. Thorner, gardener to T. M. Shuttleworth, Esq., Howick House, Preston, was first. His plants were mostly large well-grown specimens of *Anthurium Scherzerianum*, *Gleichenia speluncæ*, *G. Mendelii*, *Statice profusa*, *S. imbricata*, *Ixora coccinea*, *Phormium Colensoi variegata*, *Allamanda nobilis*, *Cycas circinalis*, &c. Mr. Todd, gardener to A. B. Stewart, Esq., Lonsdale, Glasgow, was second, his twelve including well-grown plants of *Davallia Mooreana*, *Erica retorta major*, *E. Marnockiana*, *E. Ansliana*, *Lapageria rosea*, *Ixora Williamsii*, *Statice macroptera*, and *Clerodendron Balfourii*. Mr. R. McMillan, gardener to J. Germond, Esq., Carbet, was third; good *Ericas* and *Crotons* being prominent in his lot.

Mr. Todd was first for six exotic Ferns, with large plants of *Todea superba*, *Lomaria gibba*, *Gleichenia speluncæ*, *G. flabellata*, *Davallia hemiptera*, and *Cibotium regale*. Mr. D. Middleton, gardener to T. A. Smeaton, Esq., Broughty Ferry, was second; and Mr. G. Reid third. For six stove and greenhouse plants Mr. Wilson was first; and for nine stove or greenhouse plants Mr. Todd secured the same place; while Mr. H. Thorner was second, and Mr. Wilson third. For three *Heaths* in bloom Mr. McMillan was first, and Mr. G. McLennan, gardener to R. W. Duff, Esq., Peteresso Castle, Kincardine, second, some of the plants being past their best. For three *Crotons* Mr. Thorner came first, Mr. Hammond second, and Mr. McMillan third, all their plants being well grown and highly coloured. Messrs. J. Stewart & Sons, Broughty Ferry, were first for specimens of *Todea superba* and *Tree Ferns*. For a single Palm Mr. Todd came first with a good plant of *Cocos Weddelliana*. *Lycopodiums* were well shown by Mr. G. Farquhar, gardener to A. Henderson, Esq., West Park, Dundee; Mr. J. Craigie, gardener to D. Robertson, Esq., Union Grove, Dundee; and Mr. Fairgrieve, Dunkeld. Some splendid *Cockscombs* from Mr. Mackie, Bridge of Earn, gained the first prize. When well grown few plants are more attractive.

Alpine plants in pots were shown in very fine condition. *Sedums*, *Sempervivums*, and *Saxifrages* were the chief objects

amongst them. For thirty varieties in pots not to exceed 6 inches in diameter, Mr. A. Paterson, Baxter Park, Dundee, was first; Mr. T. H. Milne second; and E. Moir, Esq., Newport, third. Mr. R. P. Brotherton, gardener to the Earl of Haddington, Tynningham, East Lothian, exhibited an excellent group, most of which were in full bloom. Orchids were very scarce. There was no competition in the nurserymen's class, and in the gardeners' there were only two threes staged; these came from Mr. Todd and Mr. Paterson, Bridge of Allan. *Fuchsias* were well shown in the amateur classes, the best coming from Mr. G. Cruicks and Mr. H. Hanton.

CERTIFICATES.—These were awarded to Messrs. Veitch & Sons for *Adiantum Luddemannianum*, *Anthurium cordifolium*, *Asplenium ferulaceum*, *Brahea filamentosa*, *Cattleya Manglesi*, *Croton MacArthurii*, *Cypripedium roseum pictum*, *C. selligerum hybrida*, *C. Euryandrum hybrida*, *Dracæna speciosa*, *Davallia Youngii*, *Eularia japonica*, *Maranta Massangeana*, *Osmunda palustris*, *Phyllanthus roseum pictum*, and *Sarracenia Venensii*. To Mr. B. S. Williams for *Alsophila plumosa*, *Anthurium ornatum*, *Anemia tessellata variegata*, *Alsophila Williamsii*, *Croton Queen Victoria*, *C. Williamsii*, *C. Henryii*, *Maranta Massangeana*, *Polystichum lepidocaulon*, *Kentia Mooreana*, *Platynerium Williamsii*, *Pandanus laciniatus*, and *Woodwardia radicans cristata*. To Mr. W. Bull for *Croton princeps*, *C. gloriosa*, *Curmeria Wallisii*, *Sadleria cyathoides*, and *Zamia princeps*. To W. Barron & Son for *Cupressus Lawsoniana pyramidalis alba spica*, *Retinospora tetragona aurea*, and *Cupressus Lawsoniana elegantissima*. Mr. Charles Turner, Royal Nurseries, Slough, was awarded certificates for the following new *Dahlias*:—*Drake Lewis*, *Elsa*, *Christopher Ridley*, and *Oracle*. Mr. A. Hunter, gardener to Lord Shand, New Hall, Edinburgh, had a certificate for *Tropæolum Hunterii*, which is a very dwarf-growing variety with a dark reddish bloom.

CUT FLOWERS.—The effect of these was somewhat lost, owing to their being arranged in various parts of the hall. *Gladioli*, although not very plentiful, were exceedingly good. In the nurserymen's class for twenty-four spikes Messrs. Robertson and Galloway, Glasgow, were first. Amongst the best in this stand were *Camille*, *Lamarck*, *Milton*, *La France*, *Ambrose Verschaffelt*, *Shakespeare*, *Primative*, *Captain Boyton*, *Ondine*, and *Argus*. Messrs. Kelway & Son were second, showing some fine spikes of *Duchess of Edinburgh*, *Mrs. Dombrain*, *Morina*, *Porcius*, *Earl of Dalhousie*, *Partheon*, and the *Rev. J. B. M. Camm*. Messrs. W. P. Laird & Sinclair, Dundee, were third. For twelve *Gladioli* in the gardeners' class Mr. Grey, gardener to W. Finnie, Esq., Newfield, Kilmarnock, was first; Mr. E. Campbell, Cone, Gourcock, second; and Mr. H. Crichton third.

All the prizes for *Dahlias* amongst nurserymen were divided between Messrs. John Stewart & Sons, Broughty Ferry, and W. P. Laird & Sinclair of Dundee. In the gardeners' class for twelve Mr. Neil Glass, gardener to J. C. Bolton, Esq., Carbrook, Stirling, was first with some extra fine blooms of *Chairman*, *James Service*, *Flora Wyatt*, *Henry Walton*, *Ovid*, *John Standish*, *Acme of Perfection*, *Miss Henshaw*, *Royal Queen*, *John Neville*, *James Cocker*, and *Vice President*. Mr. A. Duncan, Greenlaw, Paisley, was second, and Mr. McLennan third. *Hollyhocks* were neither superior nor plentiful. The best came from Mr. G. Dingwell, Ardock, Dracæ. *Roses* were very poor, and do not call for any special remark.

French and African *Marigolds* were exceedingly fine. For French varieties Mr. J. Galloway, Colinsburgh, Fife, was first, and Mr. M. Cuthbertson, gardener to J. Dobbie, Esq., Rothesay, was first in the other section. *Asters* were also well shown, as were also *Phloxes*, *Pentstemons*, and cut flowers of other herbaceous plants.

DINNER-TABLE DECORATION, BOUQUETS, &c.—There was a poor competition for the dinner-table decorations, only three appearing in this class. The first prize was awarded to Mr. James Whitton, foreman, Glamis Castle. This table, which was considerably in advance of the other two, had a centrepiece of flowers with a plant of *Dracæna Draco* on each side, which were rather large or spreading for the width of the table; small flowers and dishes of *Pines*, *Grapes*, *Peaches*, &c., completed the arrangement. The winner of the second prize was Mr. Ross, St. Martin's Abbey, Perth; Mr. J. Young, Nethergate, Dundee, being third. This part of the Exhibition was largely patronised, and it is a pity there was not what might have been termed a really first-class arrangement amongst them.

We never saw more bouquets shown together in Scotland. With one or two exceptions every one of them was composed of as many flowers as might have made three bouquets of the same size. Mr. W. Bron was first for the table bouquet, and for three hand bouquets Mr. D. Middleton was first and Mr. G. MacIure, gardener to John Milne, Esq., Edinburgh, was second, and D. & W. Croll, Castle Street, Dundee, third. Mr. W. Milne, Woodhouse, Loughborough, Leicester, was first for the button-hole bouquets, and W. P. Laird & Sinclair second. We could not entirely comprehend what was aimed at in some of the floral devices, excepting one, which was a very good imitation of a revolving fire-squirter at an illumination. The miniature

flower gardens were mostly good in design, but much in want of something green to tone down the glare of colour. A very good window garden box was shown by Mr. Thomson, 10, High Street, Dundee.

**VEGETABLES.**—These made a very excellent display, indeed we have rarely seen a finer, and for quantity this department quite surpassed anything that has been seen this year. In many of the large baskets there would be two good barrowloads of vegetables, and although roughly put together the produce was mostly of a very superior kind. Mr. Low, gardener to J. Paton, Esq., Viewforth, Stirling, was first for the fifteen sorts; Mr. P. McArthur, Newport, second; and Mr. H. Morrison, third. Turnips, Carrots, Parsnips, Celery, Leeks, Onions, Beet, &c., were grand. Mr. Rust was first for two Cauliflowers; Mr. E. Campbell second; and Mr. D. Lamond third with a couple of Veitch's Autumn Giant, one of which was the finest head there. Peas were poor. Cabbages, Savoy, Early Greens and such like were first-rate, but Cucumbers were very small. The prizes offered by Mr. Munro for a brace of his Duke of Edinburgh were gained by Mr. H. Fowler; Mr. J. Methven, gardener to Col. Campbell, Blytheswood, Renfrew; and Mr. J. Brown, gardener to C. S. H. D. Moray, Esq., Crieff, but none of their fruit as well as any of the others showed the true character of the Duke.

Potatoes were numerous and of fine quality. For twelve varieties Mr. T. H. Miln, Linlathen, came first with fine tubers of Royal Ashleaf Kidney, Robson's Challenge, Snowflake, Fenn's Early White Kidney, Fenn's Perfection Kidney, Breese's Peerless, White Don, Cheshire Chester, Gauldry's Early, and Smith's Early. Mr. Fairgrieve, Dunkeld, who was second, had some good tubers of Early Rose, Sutton's Floumball, Dalmahoy, Excelsior, Fortyfold, and Paterson's Victoria. Other prizetakers were Mr. Farquhar, Mr. Cowieson, Mr. P. Robertson, Mr. J. Thomson, Mr. P. Nicholl, and Mr. T. Aublett; the best tubers in their collections being Vermont Beauty, Early Vermont, Early Goodrich, Webb's Improved Kidney, Sutton's Hundred-fold Fluke, and American Rose.

**MISCELLANEOUS EXHIBITS.**—Messrs. James Veitch & Sons exhibited a large number of fine orchard-house trees in pots, each one bearing a splendid crop of fruit; the varieties being chiefly Salway, Magdala, and Sea Eagle Peaches; Byron, Pine Apple, and other Nectarines; different kinds of Pears, &c. These were quite a new feature at the Scotch shows, and they were greatly admired. The same firm sent some Vines in pots ready for fruiting of this year's growth, and their fine development was the subject of general remark. Messrs. Dickson & Co., Edinburgh, sent a stand of cut Viola blooms, the best of which were The Tory, Pillrig Park, Peach Blossom, Alpha, Golden Bedder, Dickson's King, Modesty, Pallada, Climax, and Picturata. A good many articles in the way of rustic flower vases and such like ornaments were contributed by local firms, but these will be of little interest to our readers. No prizes were offered for pot Vines, but Mr. McDonald, Kinnettles, sent Black Hamburgs in fruit, which were awarded an extra prize.

The Judges were as follows:—*Fruit*, Mr. Thomson, Tweed Vineyard, Clovenfords; Mr. Fowler, Castle Kennedy; Mr. Dunn, Dalkeith Park; Mr. Webster, Gordon Castle; Mr. Cole, Feltham; Mr. Mathieson, Meikleour. *Plants*, Mr. Thomson, Drumlanrig; Dr. Moore, Glasnevin; Mr. B. S. Williams, London; Mr. J. MacNab, Royal Botanic Gardens, Edinburgh; Mr. Fraser, Canonmills; Mr. T. Baines, Southgate, London. *Cut Flowers*, Mr. Downie, Edinburgh; Mr. Wyness, Montrose; Mr. Paul, Paisley. *Vegetables*, Mr. Connacher, St. Fort; Mr. Mitchell, Panmure House; Mr. Laurie, Edzell; and Mr. Gow, Hallyburton.

### FEATHERED HELPS IN GARDENS.

"TYRONE INCUMBENT" says that he differs from me as regards bantams eating slugs, as he has tried his fowls with them over and over again, and found them an object of dislike. I think his experience and mine may be easily squared though seeming so different. Fowls are grain-eating birds; they, however, take animal food in different forms as relishes, not as their staple food. When in a garden they delight to pick up small insects, worms, slugs, &c., and if they are at liberty the whole or part of the day, they, eating the small things, cause in time a garden to be marvellously clear of these pests. But collect a whole mass of slugs, most probably the largest, and give them as food, the birds are then disgusted with them.

This is not peculiar to birds. Here is my fox terrier: if I throw him a large hunch of bread he will not eat it, but if I break it into dainty morsels he catches each in his mouth and eats it, adding a grateful wag of his tail. There are my pigeons: if I give them a huge Lettuce they don't touch it, but they delight to pluck in the garden at the growing plants. There is in the case of the bantams the search, the scratch, the find, "the sport," so to speak, and the run of the hens after a dainty morsel. Bantam chicks will clear a bed of Mignonette of

caterpillars, delighting in the work, but I daresay would not eat them if shut up. They will pluck clean of aphides a Rose branch. All this I can testify from observation. But a loathsome mass of huge slugs cast in a heap before bantams would be left by them.

Sparrows, too, cleanse Cabbage plants, delighting to hunt for the caterpillars. Ducks are, of course, insectivorous naturally, and will demolish slugs, snails, &c. I have been told that the Emerald Isle, green from its humidity, abounds much more than our drier and browner England in slugs, snails, &c. Given a small garden, and a few black bantams—they are not inclined to straying so far as some others—and that garden will in time become singularly free from insect pests.—WILTSHIRE RECTOR.

### NOTES AND GLEANINGS.

**ARCHER'S COURT**, noticed in our last, is a manor in the parish of River held in the reign of Edward I. of the king *in capite* "by the sergeantry and service of holding the king's head between Dover and Whitsond as often as it should happen for him to pass the sea between those ports, and there should be occasion for it."—(*Rob. Esch. N. 34.*) It was then held by Solomon de Champs, from whom it descended to a family named Archer or L'Archer, from whom it derived its name.

The useful discussion meetings of the WIMBLEDON GARDENERS' SOCIETY began on the 8th inst. in the lecture hall of the village library, when Mr. Ollerhead commenced the reading of a comprehensive essay on winter-flowering plants. The chair was occupied by Mr. Lyon, gardener to A. Schlusser, Esq. The evenings are as yet too short, necessitating a late hour for the commencement of business, to ensure a large attendance, yet about twenty gardeners attended, several of whom took part in the discussion and supplemented the reading of the paper by the expression of useful hints. The plants noticed were the Poinsettia, Euphorbia jacquiniiflora, Eucharis amazonica, Centropogon, and Scutellaria. The reading of the essay will be resumed at the next meeting, and in due time will be placed at our disposal according to an intimation obligingly furnished by Mr. Ollerhead. Votes of thanks to the Chairman and to the author of the essay brought the proceedings to a close.

SALT brine impregnated with the blood, &c., of herrings or other fish is a good manure. Mixed with five times its measure of water it may be applied between the rows of any of the Cabbage tribe, and to Rhubarb, Beetroot, and Artichokes, says one who has tried it.

AN INTERNATIONAL EXHIBITION will be held in CAPE TOWN in 1877 in a building to be erected for the purpose by consent of the Colonial Government. It will include manufactures of all kinds. The date fixed for the opening is February 15th, and everything intended for the Exhibition must be shipped from London not later than during the first week in December, 1876. Intending exhibitors should communicate immediately with Mr. Edmund Johnson, Commissaire Délégué, at the European Central Offices of the Exhibition, 3, Castle Street, Holborn, London.

MR. J. GADD writes, "I have found the CUCKOO most helpful in ridding large plantations of Gooseberry trees from caterpillars, and by leaving the birds unmolested they have become comparatively tame, not caring to fly away at the approach of anyone."

"I have grown CANADIAN WONDER BEAN for four years and have proved it an enormous cropper, but it requires planting a good distance apart so that each plant may develop itself."

"Of the NEW PEAS DR. MACLEAN is one of the best, coming in as a second early, a good cropper, with large pods well filled, and good in quality, and being dwarf a most useful Pea for small gardens. Of the tall Peas none have stood out the dry weather like Williams's Emperor of the Marrows, and for quality nothing surpasses it."

MARÉCHAL NIEL ROSE, writes one of its very successful growers, never produces its blooms so freely as from shoots which are made in September. Shoots which are now being made should therefore be preserved, cutting away any weak, scrubby, spur-like parts of the bush in order that the free-growing shoots can have light and air to mature them. Very luxuriant shoots which occasionally appear, and which appropriate too much the sap of the bush, should be stopped, and the growth will consequently be equalised. Free-growing, moderately strong growths should be encouraged, and these if not

shortened, or shortened but very slightly, will be covered next summer with "golden flowers," such as no other Rose nor other plant can produce. A little assistance in the way of pruning given to Maréchal Niel now will be more effectual than will any amount of cutting performed in the winter.

— We have received from the Rev. H. H. Dombtrain a remarkable example of FASCINATION OF GROWTH IN THE CUCUMBER. On the portion of Vines sent to us there were twelve fruits showing in a length of stem of 3 inches, six of the fruits being from 6 to 9 inches in length, the others smaller. The stem was quite flat and  $1\frac{1}{2}$  inch in diameter. The cluster presented a very singular appearance.

— EUPHORBIA JACQUINLEFLORA is well known as one of the most brilliant and effective of winter-flowering plants. Especially as affording elegant sprays for cutting for room-decoration is this plant valuable. In order to produce these sprays in the greatest abundance and in the finest condition the plants should be planted out. The best place for planting them and the mode of growing and training them is that which has been this year adopted by Mr. Ollerhead at Wimbledon House. At the back of the Pine pits about a foot of the plunging material was removed and replaced with soil. In this a row of Euphorbias was planted close to the back wall of the pit, and three rows of wires were stretched, supported by sticks, to train the plants to. These plants now form a hedge about 4 feet high, and in due time will produce thousands of brilliant sprays which cannot fail to be of great value. The heat of the Pine stove and full exposure to light have been exactly suitable for the robust growth of the Euphorbias, and they do not in the slightest degree interfere with the Pines. The Euphorbias in fact form an agreeable hedge, and occupy space which is invariably unoccupied. We have never seen this plant so perfectly "at home" as in the place and by the mode of culture now referred to, and we have seldom seen any practice more worthy of note and imitation.

— Amongst the numerous decorative plants employed in the ornamentation of BATTERSEA PARK may be seen plunged in the grass standard plants or miniature trees of the POMEGRANATE—*Punica granatum*. These arrest the notice of visitors by their bright scarlet blossoms, which are freely produced. The stems of these plants are about 2 feet in height, and their heads are 2 feet in diameter; the foliage is healthy. These specimens are thoroughly distinct in character from the surrounding subjects, and are both novel and effective.

— The splendid dish of CRAWFORD'S EARLY PEACHES recently exhibited before the Fruit Committee of the Royal Horticultural Society denote that this fine American Peach is worthy the attention of those proposing to add to their collections. The fruits were exceedingly large, nearly round, and of an orange colour mottled with red. This is a most distinct and imposing variety, and is found by Mr. Miles to be of excellent quality, and the tree is hardy and a free bearer. Dr. Hogg, in the "Fruit Manual," describes this as a "very large and most delicious Peach, with a yellow flesh like an Apricot, and is deserving of very extensive cultivation." At the fine exhibition of Peaches at the Alexandra Palace last year Mr. Coleman easily secured the first prize with Crawford's Early, and we are informed by others who have grown it that it is a variety of the first order of merit.

— M. NADAILT DE BUFFON, a French *savant*, has sent to the Society of Acclimatisation, through M. Dronyn de Lhuys, the HERBARIUM collected by Daubenton, the great friend of his illustrious ancestor. The herbarium was collected at Montbard when Daubenton was busy in the erection of a sheep-house, which led to the introduction into France of the first merinos.—(*Nature*.)

— At the usual monthly meeting of the HORTICULTURAL CLUB held at the Club House, 3, Adelphi Terrace, on Wednesday last, the following gentlemen were admitted members:—John C. Quennell, M.D., Brentwood, Essex; A. B. Cater, Bath; and Joseph F. Mestin, 20, Spring Gardens, S.W., and Haverstock Hill.

— PROPAGATING XANTHOCERAS SORBIFOLIA. — M. Rivière states that this beautiful new shrub is rather difficult to raise from cuttings in the ordinary way, but that it may be propagated with the greatest freedom by means of root-cuttings formed from small portions of the root.

— We omitted to note that Mr. George of Putney Heath exhibited blooms of his new seedling IVY-LEAVED GERANIUMS at South Kensington last week. The new varieties, both in

colour and the form of their flowers, far surpass the older sorts. The flowers exhibited were of a rosy salmon colour, and of a shape resembling the zonals. The new seedlings are also very compact in habit and floriferous.

— THE Journal of the Society of Arts states that chief among the timber trees of New Zealand is the KAURI PINE. These trees in some instances have been found 15 feet in diameter and 150 feet in height. On an average they may be estimated as yielding, when sawn into conveniently-sized boards, between 6000 and 7000 feet of timber, the market price of which at the mills is from 9s. 6d. to 11s. 6d. per 100 feet. The wood is in great demand for cabinet-making, which gives it a special value. An illustration of this occurred some time ago, when a tree was cut by a settler residing about eighteen miles north of Auckland. The trunk of this tree was 40 feet high and 37 feet in circumference, and it yielded when sawn 22,000 feet of rich mottled Kauri, which was sold for £500, leaving, after deducting £200 for expenses connected with the cutting of the tree and getting it to market, a clear profit of £300. The gum which exudes from the tree is especially an Auckland product, being found in no other part of the world. Over a large area of land which has been exhausted by Kauri forest in past ages, and is now barren and almost unfit for cultivation, the gum that has exuded from the dead trees is found at a depth of 2 to 3 feet. This gum is an important article of commerce, being found valuable for the manufacture of varnish; and its importance may be estimated from the fact that in the last three years for which the statistics are complete—namely, 1870, 1871, and 1872—no less than 14,276 tons of the gum were exported, the value of which amounted to £497,179. The production of this article is entirely due to the aboriginal natives, and to this they are stimulated by the presence of European purchasers. The buying price of first-class Kauri gum at Auckland in March, 1874, was £30 to £33 per ton. At that price the gum-diggers would earn from 80s. to £4 a-week, according to the nature of the field they were working on. The average earnings would, however, be about £2 a-week.

— PRESERVING THE COLOUR OF DRIED FLOWERS.—M. Boulade recommends the following plan for preserving the colours of flowers of the herbarium:—Lay out the flowers between several sheets of unsized paper—filtering paper; place these sheets between two fire-bricks, and put the whole in a stove or oven heated to 60° to 70° Cent. Change the papers after an hour. After two or three hours the flowers will be sufficiently dried, and their colours preserved.

— LYCOPERSICUM CERASIFORME.—A friend writing from Leyden last week, after alluding to some of the more interesting objects with which he was impressed on visiting the Botanic Gardens, specially alludes to this plant, and he seems to have been greatly impressed with its beauty. He says, "There is now a little plant, *Lycopersicum cerasiforme*, in the open border, which is indeed very beautiful. It is literally covered with a profusion of large scarlet flowers, the effect of which is splendid."—(*Irish Farmers' Gazette*.)

## NEW EDITION.

*Choice Stove and Greenhouse Ornamental-leaved Plants.* By BENJAMIN S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London.

FROM the great success of the author as a cultivator of plants his works have met with a large share of acceptance by horticultural readers. A second edition of the work relating to ornamental-foliaged plants having been called for, an excellent volume is produced containing notices of plants which have been introduced since the issue of the first edition, and much fresh practical matter is also incorporated. The work contains reliable information on all matters relating to the cultivation of plants. It is full, yet concise; is intelligibly written, and is worthy of a place in every gardener's library. As better showing the nature of the work we extract from the preface:—

"The cultivation of ornamental-leaved plants is much easier than that of plants grown entirely for the beauty of their flowers. This will be readily understood on a moment's reflection. To produce plants profusely adorned with flowers close attention is required in resting, in shifting, and starting into growth at the proper season, and other matters of importance, all which is fully explained in the volume devoted entirely to the ornamental-flowering plants; but the plants now under consideration have to be treated upon quite a different principle, for as their beauty is to be sought in their foliage, the object should be to make

them grow as vigorous as possible from the earliest stages, so that their characters may be seen at an early period of their existence, and those kinds which are not deciduous require to be kept in a growing state nearly the whole year, which differs materially from the treatment necessary for most plants required to produce a large crop of flowers. The deciduous or annual-leaved kinds, such as *Caladiums*, give very little trouble, but yield an abundance of their charming leaves provided an ample supply of water and moderate heat be maintained. The details of cultivation will, however, follow in its proper sequence, and therefore need not be further referred to here. Let us rather address ourselves to dispel the too prevalent idea that the class of plants to which these pages are devoted require a great amount of heat. This may indeed be true in regard to most of the plants from the low grounds of the islands in the Indian Archipelago, and also from most other low countries within the tropics, and that a great many plants of this class require ordinary stove heat we do not attempt to deny, but rather add they will not exist without it; but between these is an immense quantity of grand 'foliated' plants which have for a number of years been looked upon as purely stove plants, but which we now find not only thrive well in the greenhouse and conservatory, but actually grow in the open air during the summer months. Nor is this any matter for astonishment when we reflect that even Palms, which we usually associate in our minds with great heat, are said to exist in abundance in the forest-clad slopes of the Andes at some 7000 and 8000 feet altitude, and the same may be said of many species from the Himalayas. With these are found many plants which would be beautiful ornaments to our cool houses if their natural positions were only more often borne in mind by the cultivator. It cannot be too strongly impressed upon the attention of collectors that an account of the position, the altitude, and natural surroundings of every plant they gather is of the greatest assistance to the practical man at home, and that through want of such knowledge many valuable and beautiful plants have been lost to cultivation after having been introduced in a living state to this country.

"Besides the Indian and tropical American plants we have moreover those of Australia, New Zealand, and the Cape of Good Hope, all of which countries supply us with an immense quantity of ornamental-leaved plants, and every year only reveals to us the fact that richer treasures are yet in store for whoever searches for them."

As evidence that the volume is not exclusively devoted to aristocratic plants we quote a useful chapter on WINDOW PLANTS AND PLANTS SUITABLE FOR INDOOR DECORATION:—

"A few years ago what little window gardening or room decoration was carried on was done by the aid of flowers only. Such as *Geraniums*, *Fuchsias*, *Heliotropes*, and a few other summer-blooming plants formed the chief supply, which was varied in winter by the addition of the Chinese *Primula* and the *Cineraria*, thus leaving the apartments empty and dreary just at the time when plants would have been most appreciated. To supply this want Ferns were first taken into favour, and most elegant decorative agents they are, but unfortunately the greater portion of them are too delicate in texture to withstand the dry atmosphere which is necessarily maintained in a dwelling-house. To obviate this miniature greenhouses were invented by Mr. N. B. Ward, an enthusiastic lover of this race of plants, and these have ever since been called 'Ward's Cases' or 'Wardian Cases,' and are most extensively used. Indeed, many large and interesting collections of Ferns are cultivated by amateurs who have no other accommodation but such as these cases afford, and to whom they thus become a never-ending source of enjoyment. In addition to their adaptability for the cultivation of Ferns, they are eminently suited also for the growth of many of the smaller-growing plants remarkable for the beauty of their leaves, and which, although too fragile to stand in a room unprotected, yet become objects of great interest when grown in cases. There are several kinds of Orchids which succeed admirably in these structures, and afford much additional interest; we allude to the various species of *Sophranites*, which are adapted for small blocks to be suspended from the roof; to several species of *Lycaste* and *Odontoglossum*; to the most showy kinds of *Stellis* and *Pleurothallis*, as well as some of the *Maxillarias* and *Cypripediums*.

"The groundwork of these cases should be composed of ornamental-foliated plants—plants with a robust constitution and somewhat stout or coriaceous leaves, examples of which may be found amongst Palms and the different species of *Dracæna*, *Croton*, *Agave*, *Yucca*, *Ficus*, and many other genera. Amongst these the plants in flower should be arranged with a view to give life to the picture. These latter must, however, be renewed as soon as the blooms are past. *Jardinettes* and vases for dinner-table decoration should be filled alternately with leafage and flowering plants to prevent sameness of appearance.

"It has occurred to us that many would be glad of a little timely advice as to the management of their open-air window plants and window boxes, and although these do not come exactly within the meaning of the heading of this chapter, we

shall be excused for devoting a little space to this object. Plants grown in pots and in boxes outside windows are in many instances miserable objects; on the other hand, many persons succeed in maintaining a gay and varied display in them nearly all the year round, which is ample proof that it is possible to do so if proper selections are made and sufficient care and attention are bestowed. Ivies of various kinds have a beautiful appearance when trained neatly round the window, and form an elegant framework for the plants, besides having a cheerful aspect during the dull winter months. During summer they may be removed if desirable, and such plants as *Pileogyne suavis* (German Ivy), *Cobæa scandens variegata*, *Hardenbergia monophylla*, and various other plants used in their place. One of the most beautiful window arrangements we ever saw was a framework of Ivy upon which was trained *Clematis Jackmanni*; another consisted of *Clematis lanuginosa candida* upon the same background. These and many other varieties of this genus cannot be surpassed for this purpose; we must, however, in passing remind our readers that they will require occasional applications of weak artificial manure to prevent them becoming exhausted—an occurrence which would only lead to disappointment and loss of time.

"In the summer season window boxes should never be without a few plants of *Mignonette*, as its delicate fragrance is not surpassed by that of any other flower. This can be easily accomplished by dropping a few seeds upon the soil every three or four weeks, so that young plants may take the place of older ones which may be robbing the other occupants of their space. One or two plants with ornamental leaves should be placed in each box, and the remaining space should be filled up with flowering plants according to the available supply. As the plants become shabby they should be removed to the store ground and their places be filled up by others. We may add that if the growth of spring bulbs is attempted a double set of boxes will be needed, so that the bulbs may be planted in autumn, covered with ashes or other protecting material, and not brought into position until tolerably advanced. This arrangement will allow the windows to be decorated with a few flowers and ornamental plants during even the depth of winter."

After making these copious extracts it is not necessary to add more than that the work is attractive, instructive, and entertaining throughout.

## WORSLEY HALL,

### THE FLOWER GARDEN AND PLEASURE GROUNDS.

THE pleasure grounds are quite sixty acres in extent, and are parted from the kitchen gardens by a belt of forest trees and an undergrowth of *Rhododendrons*, through which we pass by a shady walk. How often do we see plantations not far from princely mansions with an undergrowth of brambles, scrubby trees, and weeds; whereas by a very little attention and not much expense Laurels or *Rhododendrons* might be planted, which form a good cover for game and add greatly to the beauty and value of an estate. Skirting the pleasure grounds are noble bushes of *Rhododendrons* and Portugal Laurels, which form in certain positions sheltered nooks. On the closely shaven lawn are a few raised beds planted with succulents. One was very effective, and had for a centre *Sempervivum tabuleforme* and *S. californicum*, with an edging of *Mesembryanthemum cordifolium variegatum* planted at intervals with a large-foliated *Sempervivum*. In this portion of the grounds are some noble specimens of *Araucaria imbricata*. Here, too, did Her Majesty the Queen plant a *Wellingtonia gigantea*, and her eldest daughter, now Princess Frederick William of Prussia, an Oak; and right well has it taken to the soil, while the Californian monarch looks wretchedly out of place and in a dying condition, the same as it is to be found everywhere in the neighbourhood of large and smoky towns. Here also we find the rosery, and it is certainly placed in a position where Roses might be enjoyed, but it is not such as would be chosen by a rosarian who wished to grow fine flowers. It is quite surrounded by a tall hedge and overshadowed with lofty trees, which are near enough to send their fibrous roots into the Rose beds. The Rose bushes looked as well as could be expected under the circumstances.

From this point we very soon reach the terrace garden in front of the Hall, where the full extent of the grounds is taken in at one view. This portion is divided from the large geometrical garden by a substantial balustraded wall. A beautiful lake four or five acres in extent terminates the dressed ground. At the south-east side of the grounds, bounded by the aforesaid *Rhododendrons* and Laurels, we notice on the banks of the Duke's Canal the Queen's landing stage; beyond that the famous foundry of Nasmyth, where the steam hammer was first used. Further still in the distance is that characteristic

Fig. 80.—FLOWER GARDEN AT WORSLEY HALL.

feature in English landscape the tall square church tower—in this instance of Eccles church. More to the south and looking over the lake in the extreme distance are the Derbyshire hills, and between our present position and the hills a railway train is speeding to its destination, and we are told that it is now in the middle of the Chat Moss. More church spires and taller chimneys vomiting sulphurous smoke, which accounts for the stunted growth of many species of Conifers, are seen; and in the far distance, and when the sky is clear, are to be seen the hills of Wales and Shropshire.

Returning to the garden, which is best described as a series of terraces sloping from the Hall to the lake, and even beyond the Hall, as there are two terraces rising on the north side, which partly serve as a shelter from the wintry blast; five terraces more constitute that portion of the ground between us and the lake. This is a noble sheet of water with a pretty little island, which it is intended to connect with the mainland by an ornamental bridge.

The geometrical garden was laid out by Mr. Markham Nesfield, but the present plan is a modification of his. Portions of the attenuated scrollwork in imitation of Brussels carpets, which he was so fond of introducing into his designs, have been turfed over, and a much more simple and appropriate plan has been the result. Small beds and elaborate scrollwork designs are not in keeping with the surroundings at Worsley Hall. On this terrace there is also a very elegant fountain designed in bronze by Valdousé. It was exhibited and much admired in the first Great Exhibition of 1851. The central group is formed of storks, kingfishers, and Water Lilies. On the lowest terrace there are also flower-garden designs, with fountains in the centre and beds of the finer Rhododendrons and other shrubs. On the west side of the Hall is the croquet ground, which is surrounded on one side with beds of scrollwork in Box and spar, and on the other with a series of circular beds.

The carriage drive from the Hall to the lodge is through an avenue of Lime trees, which had been planted too close to the side; and although they are of considerable size Mr. Upjohn has successfully transplanted a number of them, removing them further from the verge. The whole of the pleasure grounds as well as the kitchen gardens are in excellent order, and reflect very great credit upon Mr. Upjohn and his staff of workmen.

A plan of one of the flower-garden designs is appended: it is laid down on gravel, the beds being surrounded by Box edging and relieved by grass. Both in design and planting it is very effective.—J. DOUGLAS.

## EARLY WRITERS ON ENGLISH GARDENING.

No. 18.

### WILLIAM CURTIS.

MR. CURTIS was the eldest son of Mr. John Curtis of Alton in Hampshire, a tanner. He was born in the year 1746. When about eight years of age he was placed under the care of Mr. Viandin, who at that time kept a very respectable school about a mile from that town. Mr. Curtis remained at this seminary under Mr. Viandin and his successor Mr. Ducker till about the age of fourteen, when, to his great regret (for he had now begun to relish and to know the value of classical acquisitions), he was taken away and bound apprentice to his grandfather, an apothecary at Alton.

It was during this period that Mr. Curtis was led to his first studies in botany. The house contiguous to that in which Mr. Curtis lived was the "Crown Inn." The ostler, Mr. John Lagg, a sober steady man, was a person of uncommonly strong sense, and, though an unlettered man, with the assistance of Gerard's and Parkinson's unwieldy volumes, had gained so complete a knowledge of plants that not one could be brought to him which he could not name without hesitation. This struck Mr. Curtis's young mind most forcibly, and brought into action those powers which have made him so famous. In a very short time his indefatigable zeal had made him practically acquainted with most of the wild plants of his neighbourhood, especially those which related to medicine.

But this first practical acquaintance with plants had been

gained under the direction of the laborious and obscure system of the old school. The Linnæan system began now to be much talked of. Mr. Curtis happened to meet with Berkenhout's botanical lexicon; and this was almost the only book on the theory of botany which he had been able to procure during his residence at Alton. His apprenticeship there now drawing to a conclusion, his friends thought it necessary that he should be settled in London.

He first lived with Mr. George Vaux, surgeon, in Pudding Lane, and afterwards with Mr. Thomas Talwin, apothecary of Gracechurch Street, to whose business he succeeded. During the period of his residing with these gentlemen Mr. Curtis attended St. Thomas's Hospital and the anatomical lectures there given by Mr. Else, as well as the lectures of Dr. George Fordyce, senior physician to that hospital. Dr. Fordyce, convinced of the necessity of botanical knowledge to medical students, was in the practice of accompanying his pupils into the fields and meadows near town, chiefly for the purpose of instructing them in the principles of the science of botany. On these occasions Mr. Curtis frequently had the honour of assisting the doctor in demonstrating the plants which occurred;

Fig. 91.—Mr. William Curtis.

frequently the talk of demonstration was confided wholly to Mr. Curtis. These instructions were gratuitous, and, no doubt, gave him that confidence of superiority which justly led him to the idea of imparting knowledge by the various modes of lecture and publication, which he afterwards so successfully pursued.

Mr. Curtis for some time gave public lectures in botany, taking his pupils with him into the fields and woods in the neighbourhood of London. Nothing could be more pleasant than these excursions. At dinner-time the plants collected in the walk were produced and demonstrated; but the demonstration was enlivened with all that fund of natural humour which was always uppermost in Mr. Curtis's disposition.

Mr. Curtis with great judgment had connected the study of entomology with that of botany, and accordingly about the year 1771 published his instructions for collecting and preserving insects; and in the year 1772 a translation of the "Fundamenta Entomologiæ" of Linnæus. He was now known to many gentlemen of the first abilities in the knowledge of natural history; among the rest to Mr. Alchorne of the Mint. This gentleman had officiated, *pro tempore*, as demonstrator of botany to the Society of Apothecaries on the resignation of Mr. Hudson, and conceiving that it would be both honourable and advantageous to Mr. Curtis to be placed in that situation, he recommended him in the handsomest

terms to the Society, and he was accordingly chosen to that office. He continued in this situation several years, but at length finding it interfered too much with his professional duties resigned it.

Before this resignation took place Mr. Curtis had become intimately acquainted with Thomas White, Esq., brother of the Rev. Gilbert White of Selborne, Hants. Mr. White was a gentleman of learning, extensive reading, and much science. In conjunction with him Mr. Curtis occupied a very small garden for the culture of British plants near the Grange Road, at the bottom of Bermondsey Street. It was here that Mr. Curtis first conceived the design of publishing his great work, the "Flora Londinensis," having the good fortune to meet with an artist of uncommon talent in Mr. Kilburn, and receiving from Mr. White, especially in his three first Fasciculi, much and most valuable assistance.

The Grange Road garden was soon found too small for Mr. Curtis's extensive ideas. He therefore took a larger piece of ground in Lambeth Marsh, where he soon collected the largest collection of British plants ever brought together into one place. But there was something ungenial in the air of this place, which made it extremely difficult to preserve sea plants and many of the rare annuals which are adapted to an elevated situation; an evil rendered worse every year by the increased number of buildings around. This led his active mind, ever anxious for improvement, to inquire for a more favourable soil and purer air. This at length he found at Brompton. Here he procured a spacious territory, in which he had the pleasure of seeing his wishes gratified to the utmost extent of reasonable expectation. Here he continued to his death.

Several years previous to this, Mr. Curtis finding it incompatible with the duties of his profession as an apothecary to give up so much of his time as he wished to his favourite pursuits, first took in a partner, and soon after declined the practice of physic altogether, devoting himself to the study of natural history. He had now nothing to depend upon for a livelihood but the precarious profits of his botanic garden and his publications. The "Flora Londinensis" was an object of universal admiration, and on this he bestowed unwearied care. But the sale of the work never equalled its unrivalled merit, the number of copies sold scarcely ever exceeded three hundred. This was owing partly to the work coming out (a great advantage to it in point of accuracy), so slowly; partly to its being but little known abroad in consequence of this slowness, and at length to the horrid revolution of France.

Mr. Curtis disdained to have the usual recourse to artifice and increased price to enable him to carry on the sale. But by a happy judgment, about the year 1787, he projected the plan of his "Botanical Magazine." What the sterling merit of his "Flora" could not accomplish, this comparatively speaking inferior performance procured him most readily. The nature of this publication had in it such a captivating appearance, was so easily purchaseable, and was executed with so much taste and accuracy, that it at once became popular; and from its unvaried continuance in excellence and popularity continued to be a mine of wealth to him to the very day of his death, contributing at the same time not a little to the increase of his botanical fame, from the number of original and excellent observations interspersed through the work.

The mode of publication adopted in the "Botanical Magazine" held out a tempting lure to similar productions. Hence, among others, the "English Botany" of Dr. Smith and Mr. Sowerby took its origin. Unfortunately Mr. Curtis considered the publication of this work as an act of hostility against himself, neither would he allow himself to be persuaded to the contrary. It was an unfortunate circumstance, and prevented him from communicating with Dr. Smith, a real friend to him, and even with the Linnean Society, of which he was one of the oldest members, and in which he had a very large number of his personal friends. No mischief arose from this untoward misconception, the interposition of friends at length softening, if not entirely healing, the rankling wound.

There was not a naturalist of any eminence who did not court his acquaintance. There never was a pleasanter companion than Mr. Curtis: he abounded in innocent mirth, and good humour ever floating uppermost gave a pleasant cast to everything he said or did. Few people have been known to form so correct an opinion of themselves as he. "I have no pretensions," said he, in the memoirs which he left with Dr. Sims, "to be considered as a man of letters or of great mental powers. I know myself and my imperfections. A consciousness of my inabilities makes me diffident, and produces in

me a shyness which some have been ready to construe into pride." He was sensible that his excellence consisted in his superior discernment when applied to objects of natural history: in that respect he had few equals. The following circumstance bears witness to the truth of this remark:—Mr. Curtis first discovered the membranous calyptra in Mosses, overlooked by Dillenius. To him we owe the discovery that the *Violas* and *Oxalis* produce seeds all the year through, though the latter produce no petals except in the spring, the former only sparingly in the autumn. The distinction between *Poa pratensis* and *trivialis* by the intrafoliaceous membrane is the result of Mr. Curtis's accurate discernment. Many others might be mentioned. From this mode of viewing objects other writers took the hint; and, undoubtedly, the science of botany was much improved by these and such like attentions.

In ornithology Mr. Curtis was no mean adept. Although his musical powers were by no means at all beyond the common level, yet in one respect he showed a most exact ear. No bird could utter a note, whether its usual one, or that of love, or that of fear and surprise, but he could from the sound determine from what species it proceeded.

Entomology was always a favourite study with him. Few men have observed more: it is only to be regretted that he committed so little to paper. He was so familiar with the motions of insects that he could almost always declare what was the intent of those busy and playful (as it should seem to ignorant observers), actions, in which they were so perpetually employed. He made a most notable discovery of the cause of what is called the honeydew on plants. From repeated observations he determined it to be no other than the excrement of aphides.

All Mr. Curtis's ideas were turned to the benefit of mankind. He was the first botanist of note in this country who applied botany to the purposes of agriculture. By perpetually cultivating plants he possessed advantages superior to any that had preceded him, and was thereby enabled to point out to the agriculturist the noxious as well as the useful qualities of plants, a branch of agriculture rarely attended to.

Although, as has been before stated, Mr. Curtis's education was very confined, he had acquired some taste for classic literature both ancient and modern, and somewhat of elegance and neatness pervaded whatever he took in hand. The form of his mind was portrayed in his garden, his library, his aviary, and even a dry catalogue of plants became from his pen an amusing and instructive little volume. His delicacy never forsook him, nor would he willingly adopt the coarse vulgar names of some of the elder botanists, though sanctioned by the authority of Linnaeus himself. In short, Mr. Curtis was an honest, laborious, worthy man, gentle, humane, kind to everybody, a pleasant companion, a good master, and a steady friend. His "Flora Londinensis" will be a *monumentum ære perennius*.

He departed this life, July 7th, 1799. The following is inscribed on his tomb:—

"While living herbs shall spring profusely wild,  
Or gardens cherish all that's blythe and gay,  
So long thy works shall please, dear Nature's child,  
So long thy mem'ry suffer no decay."

The remains of Mr. Curtis were deposited, at his own request, in Battersea churchyard, opposite the west entrance of the church; a place selected by him, probably from its being a pleasant place, adjoining the Thames, and the neighbourhood of frequent scenes of enjoyment in herborising excursions with his pupils, for which the weedy fields of Battersea were a peculiarly desirable spot.—(*Gentleman's Magazine*, &c.)

## PROFITABLE TIMBER TREES.

A CORRESPONDENT proposes to plant about ten acres of land on a hillside, the soil being clay on chalk. He wishes to plant this with trees, which must be cleared off in from twenty to thirty years, and asks which will in that time give him the greatest return by the sale of timber? "His proposition is to plant Larch 3 feet apart each way, and some quick-growing and more valuable timber at about 12 feet apart, such as Ash, Beech, Acacia, Chestnut, Lime, and Sycamore," which he assumes will become of more value in the time named than the Larch of the same age. He further propounds the following series of questions—"1, Are the trees mentioned such as you would recommend for a quick growth and value as timber, and would Black Poplar do with Larch or overgrow it? 2, Would 3 feet apart be too close, and do you consider it a suitable distance?

3, What preparation should the land have? I could not afford to trench it. 4, Is October and November a better time to plant than February or March? 5, Would the land pay for manuring before the planting is done? It has grown a crop of Barley and Potatoes this summer. 6, What would be the probable value of the timber per acre at the end of twenty-five years, including the thinnings previous to that time?" The matter of tree-planting is one of general importance, and the above questions in reference thereto are very pertinent; we therefore publish them with the following commentary from one who has had experience in tree-planting and the management of plantations.

I will consider the above questions seriatim, and first say that I do not agree with the proposition of planting such trees as Ash, Beech, Acacia, Chestnut, Limes, and Sycamore 12 feet apart, with Larches between them as nurses. I observe that your querist does not include Oak, he probably having in mind the adage that "Larch will buy a horse before Oak will buy a saddle." That I believe to be true, and not only so, but I am firm in the opinion that Larch where it grows well will buy a horse sooner than will any other timber tree. It may, however, not be unprofitable to notice briefly the characteristics of the trees mentioned by way of determining their adaptability or otherwise for the purpose named—i.e., of affording the greatest profit in, say, thirty years.

**ASH.**—A hardy tree of rapid growth in good and especially moist soils. The growth in a young state is useful for crates, hoops, hop poles, and fences, and when matured is in great request by wheelwrights for various purposes. On a chalk subsoil the young growth would probably be too slow to be profitable, and as the trees would not be matured in less than forty to fifty years the Ash must be ruled unsuitable for the present object.

**BEECH.**—Very hardy and grows freely, especially on the limestone and chalk, but the wood in a young state is proverbially not durable. When matured it is by its closeness valuable for tools and furniture; but as the Beech cannot with certainty be perfected in thirty years it also must be "out of court."

**ACACIA** (*Robinia pseudo-acacia*).—Hardy and a quick grower in a young state. When matured its timber is extremely durable, but the tree does not arrive at maturity in the time named. It is a handsome but not a profitable tree.

**CHESTNUT.**—Neither the Sweet nor the Horse Chestnut can be regarded as profitable trees, although they are quick growers in good soils.

**LIME.**—This is also a quick-growing, hardy, and handsome tree. Its wood is soft, and is useful for turning and for musical instruments. The Larch would buy a horse before the Lime would a donkey.

**SYCAMORE.**—This is a very hardy tree, and grows freely in almost all soils. When its wood is matured it is always in request, but in a young state it is comparatively valueless. For early profit it is greatly inferior to the Larch.

**BLACK POPLAR.**—This tree also is mentioned. It is the quickest-growing of all, and its timber is useful for many purposes, and is less inflammable than most wood. It spreads and overtops most trees, and in that respect is occasionally injurious to its neighbours. The wood yields no profit for many years, and in this respect is certainly inferior to Larch. Larch, therefore, I consider must be relied on to produce the greatest profit in the time stated, and thus question No. 1 is disposed of.

As to question No. 2—distance of planting—I regard 3 feet as being fully too close. The practice on the estate with which I have experience is to allow four thousand trees per acre, which is nearer 4 feet than 3 feet apart, and that practice has answered well.

3, Preparation of the land. This is an important matter. First see that it is well drained, and let me remark that in draining land for trees shallow drains are useless; to be effectual the main drains should be 4 feet deep. The ground cannot be trenched. The next best plan, and it would be very profitable, would be to have it deeply dragged with the steam cultivator, going over it several times. This would loosen the subsoil to a depth of 14 inches. A little first cost in this respect would be true economy. At any rate work the soil as deeply as possible, bringing it by repeated draggings into a free workable state, such as is necessary for a crop of Potatoes. That will compensate for manure, which answers question No. 5.

I will now take the question preceding—No. 4, as to time of

planting. Where the land is in a pliable state and rabbits do not abound I advocate planting in November, otherwise I would defer it until February or early in March. I have known thousands of trees which have been planted in November completely ruined by rabbits during a severe winter following, and the work of planting many acres has had to be done over again in the spring. Again, if the soil is of a very heavy nature it cannot, without much labour, be made sufficiently fine for placing round the roots of the trees immediately after the holes are dug for them, whereas if the holes are made early in the autumn the soil becomes ameliorated by the frost and air, and during the fine weather of early spring a portion at least of it crumbles down, enabling the planting to be well and expeditiously done. My advice, therefore, is in rabbit-infested districts to plant early in spring, and when the ground is heavy to make the holes for the trees in the autumn, planting afterwards when the weather is suitable and the soil has become in a useful measure pulverised. Having the land well drained and thoroughly working it are measures of the greatest importance in ensuring a quick and satisfactory growth and a profitable return on outlay. By adopting these means and planting Larch I have seen hundreds of acres of land that did not bring in a shilling a-year to the owner, brought into a condition so as to be regarded as satisfactorily lucrative, equalling in this respect the agricultural land under tillage on the best portions of the estate. If such results can be attained by planting trees on bad land, what may we expect from land that is in good cropping condition?

I now come to the last question, as to the probable value of timber per acre at the end of twenty-five years. It is impossible to answer that question, as so much depends on the progress which the trees make and the way in which they are managed. I can say that Larch plantations which thrive well and are judiciously managed will yield a clear profit of £3 per acre over any number of years sufficient for the trees to become matured.

Larch is the most profitable of all trees where quick returns are required. The trees are of rapid growth, and in a very few years (six to ten) the trees are of a sufficient size for many useful purposes, and the thinnings of well-grown trees of that age always sell readily. Larch possesses this advantage over almost all other trees, that the wood is valuable when in a quite young state. When used as stakes or poles—hop poles, no other are so endurable as Larch. In its larger stages when used for rails and fences, and even posts, no other timber is so good at its price and none, save Oak, and this must be matured, lasts so long. When still further advanced Larch is in continual request by railway companies for sleepers and by proprietors of mines for supports, and for general agricultural purposes; also for scaffolding it is the most useful of all timber. Its bark also is valuable, and is always saleable at remunerative prices for the tannin which it contains. A greater number of trees can be perfected on a given space than of any other kind of tree; in fact, it combines qualities, which are advantages to the grower, in a greater degree than does any other tree with which I am acquainted.

It will grow anywhere if well treated—that is, if the soil is well drained and kept free from stagnant water. It is not enough to drain at the first and suffer the drains to become choked afterwards. Already there has been too much money wasted in that kind of draining. The drains must be good and kept clear at their outlets, and then will the soil be kept in a healthy state, and the trees will continue to improve and prosper until they attain to maturity.

In making holes for trees do not be afraid of the spade. A large hole takes scarcely any more making than a small one, and when the spade is on the spot it is only the work of a moment to sink it into the bottom of each hole, loosening the soil thereby to a depth from the surface of 16 to 18 inches. Planting must also be carefully done, and the roots of the trees should not be exposed to the drying effects of the air a moment longer than is absolutely necessary.

Where winged game is required it is well to plant a Spruce Fir here and there, and especially at the margins of plantations, starting with the Spruce in the fourth row from the margin, and placing a tree in every fourth hole. Another row behind that and the same distance from it as the trees are apart, forms an evergreen fringe affording shelter and privacy to the "feathered friends" which are frequently so greatly valued and jealously preserved.

When plantations of Larch are formed solely for growing hop poles (which I am informed is lucrative) the trees are

planted as closely as 2 feet apart. For this purpose of growing Larch I have had no experience, my practice having been limited to plantations established for growing useful timber. The trees should be thinned so soon as there are signs of crowding and when the lower branches show evidence of decay—not waiting until decay has set in and the bottom branches perish, for then injury is done which is in all probability irreparable. On the other hand the trees must not be thinned too soon or too severely, or the upward growth will be less rapid and the poles less regular and less straight. There are thousands of acres of land which are now useless which might be rendered profitable by being planted with Larch and properly tended, and I am glad to see that attention is being given to a subject which is unquestionably of national importance.—A FORESTER.

### ROSE ELECTION.

THE poll will close on Wednesday, September 20th. Any Rose-growers wishing to record their opinions will kindly communicate their replies to me at once, as there is much to do before publishing, and I wish the result to appear if possible this month or the first issue in October. I repeat the questions.

1, Name the fifty best Roses in cultivation according to your judgment. Underline the best twenty of these.

2, What is the best stock for Roses?—JOSEPH HINTON, *Warminster*.

### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*LILIU PHILLIPINENSE*. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia. Flower white.—“It is a native of the Philippines, and was sent by Mr. Wallis to Messrs. Veitch, and first flowered by them in August, 1873. Whether it will prove hardy still remains to be seen, but the mountains in the Philippines are said to reach a height of 10,000 feet. Botanically it is interesting as showing the extreme development of the peculiarities that mark the Eulirion group.”—(*Bot. Mag.*, t. 6250.)

*LYCASTE LASIOGLOSSA*. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Flower yellow.—“*Lycaste lasioglossa*, so named from the hairy lip, is a native of Guatemala, from whence it was imported by Messrs. Veitch.”—(*Ibid.*, t. 6251.)

*BEGONIA DAVISII*. *Nat. ord.*, Begoniaceæ. *Linn.*, Monœcia Polyandria. Flowers scarlet.—“It was discovered in Peru, near Chupé, at an elevation of 10,000 feet, by Mr. Davis when collecting for Messrs. Veitch, and it flowered in their establishment in July of the present year.”—(*Ibid.*, t. 6252.)

*DRACENA FRUTICOSA*. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia. Flowers green.—“The plant has the general habit and lax leaves of the Mauritian and tropical African *D. reflexa*, Lam., but is more robust, with larger leaves and flowers, and a longer perianth tube. It flowered in the Palm house at Kew in April, 1862.”—(*Ibid.*, t. 6253.)

*ONCIDIUM STRAMINEUM*. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of the mountains of Mexico, and requires cool treatment.—“*O. stramineum* belongs to a small section of the genus, and according to Lindley is easily recognised by its rigid unspotted leaves, not keeled at the back; its flowers have a faint primrose odour. It first flowered at Kew in May, 1866.”—(*Ibid.*, t. 6254.)

PEACH—*Grosse Mignonne*.—“It is most desirable that this, one of the best of all our large mid-season Peaches, should be well known among cultivators, and so indeed it is, and fully appreciated by the most intelligent amongst them. A walk through many a country house would, however, prove that this knowledge, though widespread, is by no means universal. The fruit is of large size, roundish, somewhat flattened, with a deep suture at top; the skin, which is clothed with thin soft down, is of a pale straw-yellow, mottled with red towards the sunny side, which is of a deep crimson or brownish-red. The flesh is pale yellow, rayed with red at the stone, from which it parts freely, melting, very rich, juicy, and highly flavoured, surrounding a small slightly-pointed stone. It belongs to the group with large flowers and round glands, and is less subject to mildew than some other sorts otherwise of high repute.”—(*Florist and Pomologist*, 3 s., ix., 205.)

### DESTROYING WASPS' NESTS.

IN a recent issue of the *Journal of Horticulture* I notice one of your correspondents recommends growing Tomato plants in hothouses as a protection for Grapes against wasps. I have had

two such plants, but directly the Grapes became ripe the wasps commenced their attack. On reading the above suggestion I thought I would surround one of the finest bunches attacked by wasps with several branches of the Tomato plant, but as far as I could see it had no effect, except in making them more determined to carry off their prey. I may say that the best way to destroy wasps' nests in the easiest, cleanest, and most effective manner is to pour benzoline down their nest, and a lighted match being applied up go the vagabonds.—J. T.

### ORNAMENTAL AND USEFUL TREE-PLANTING.

No. 5.

WE turn next to the sub-genus of the *Abies* which is known by the name of *Picea*, and of which the best known species is the common Silver Fir, or *Picea pectinata*, which owes its introduction to this country to Serjeant Newdigate, its importer from Switzerland in 1603. Of slow and critical early growth, it makes up for this by rapid strides after 4 or 6 feet of growth; but it does far better in moderate shelter than as a tree in the open, yielding finer and more close-grained timber when grown *en masse*. It is observed by Grigor that it is unfitted for the elevations suitable to native Pine and Larch, and in its original haunts is not unfrequently associated with the Oak. At Long-leat there is a Silver Fir 125 feet high and 4 feet 6 inches round. Another, in Herefordshire, is more than 120 feet in height, and has a girth of 11 feet 9 inches at 5 feet from the ground; but few other such are to be found in the English counties. Its upper leaf is of a shining dark green, with two silver lines on each side of the midrib beneath. Like the common Silver in habit, though not in the glossy green of its shoots and foliage, the Californian *Picea grandis* claims a vacant space in plantation or pinetum, where it will weather the late frosts which check the early growth of many of the Silver Firs. Its forty years' experience of English soil promises a magnificent Conifer in the future, as it is said to reach 200 feet in its native country. An odd fifty is said to be added to this tale in California by the *P. amabilis*, of the same date upon English soil, and of bright green hue, with glaucous under foliage. But the most distinct, if not the hardiest, of Californian Silver Firs which we have naturalised is the *P. bracteata* (1857), a slender straight-stemmed tree, with bright green leaves above, and ribbed with two silver lines below. Its bracteæ, or leaves of inflorescence, are wedge-shaped and peculiar. Its habitat is in the limestone districts, into which, therefore, the owners of English chalk-lands should introduce it; and it has been observed that its tendency to start too early into growth, only to be checked by a late frost, may be corrected by planting in a north or west aspect.

But even the stoutest of new-world *Piceas* fails to match in constitution the Crimean *P. Nordmanniana*, introduced in 1845, and apparently unsusceptible of frost and indifferent as to soil. In forty years it has attained 38 feet at Dropmore, and in its own mountains its maximum is 100 feet. The secret of its unbroken vigour appears to lie in its not beginning to grow till the season is well advanced; but what is manifest is that it makes rapid growth, waxes a great and well-balanced tree in a few years, and is as ornamental in its dense clothing of light green foliage as it is useful (we are told) for its good and hard timber. Two other Silver Firs deserve mention—the *P. cephalonica* for its dagger-shaped foliage of dark shining green and regular tiers of branches, on which it stands nearly at right angles. Its stem is apt to be bulky in proportion to its height, and it thrives best near the seacoast. It is found in different mountain districts of Greece, but was introduced to England from Cephalaria in 1824. Not unlike it in its earlier stages of growth is the Spanish *P. Pinsapo* (1836), but the latter is broader in leaf and less particular as to soil and situation. It is a cylindrical tree in habit, with a sluggish leading shoot but vigorous laterals, which require space and elbow-room. Deservedly a favourite, it merits a place in the pinetum and the shrubberies, as witness the engraving at page 18 of Mongredien's “Trees and Shrubs.” The Indian *Pindrow* and *Webbiana* have their respective merits as ornamental *Piceas*, the former in its upright growth, the latter in its ultra-silvery underleaf. But these scarcely realise in little the descriptions that come of them from the Choir Mountains; and here, at least, they are not likely to make good or sound timber.

Before quitting the subject of the Fir tribes a passing tribute is due to the Larch, as of all Conifers that which has proved most useful and profitable to British planters. But the Larch

is so common, so remunerative, and, for its peculiarity as a deciduous Conifer, with the brightest of green leaves in early spring-tide, so memorable, that its merits will not brook epitomising. There are one or two of these, however, for which we must claim a word. Mr. Mongredien gives its height 80 to 100 feet; Grigor quotes Larch at Paradise, in Aberdeenshire, at 102 to 106 feet high; and we have seen Larch felled in the south of England 96 and 104 feet. A disposition to be sceptical, too, has in some periodicals lately cast a doubt on the fertilising effects of the Larch foliage annually shed. And yet what is more natural than that for a tree, whose native habitat is a rocky mountain slope, with a soil composed of *débris*, this sort of deposit should be a provision of nature, along with the percolation of moisture, supplying nourishment and forfending drought? The experience of Mr. Grigor on this subject carries great weight:—

"No tree," he writes, "is so valuable as the Larch in its fertilising effects, arising from the richness of its foliage, which it sheds annually. In a healthy wood the yearly deposit is very great. The leaves remain and consume on the spot where they drop, and when the influence of the air is admitted the space becomes clothed in a vivid green with many of the finest kinds of natural grasses, the pasture of which is highly reputed in dairy management. And in cases where woodland has been brought under grain crops, the roots have been found less difficult to remove than those of other trees, and the soil has been rendered more fertile than that which follows any other description of timber."—(*Grigor*, p. 233)

Again, it has been urged against the Larch, with some show of reason, that when leafless its contour and character in a plantation is the reverse of ornamental. In a plantation, granted; but in the open ground, where care and culture may coax it to show its capabilities, few trees are so strikingly picturesque in point of stem and lateral branches. Whether, as we have seen it proposed, it is safe to dock the top of a young Larch in the open ground, by way of making it throw its growth into side shoots, we dare not give an opinion; but certainly where accident has anticipated the experiment, the result is a remarkable stem clothed from bottom to top with graceful and pendulous branches.

A glance at their leading representatives must suffice for such other tribes of the natural order of Coniferae as the Cedars, Cypressess, and Junipers; as also for the new family, of which the Araucaria is chief, and that very old and indigenous kindred, though not strictly coniferous family, the Yews or Taxaceæ. All these make valuable contributions to modern parks or gardens. There is little need to dilate upon the Yew, whether in its familiar English form or in its fastigate Irish variety. Both are in their place in ancient churchyards, and the former doubtless adds a prestige to those spots of old England with which it has been connected since the Conquest; but except for the sake of sentiment, individual specimens add little to the greensward, though they are a thing of beauty and trimness when consolidated into a hedge, and have a weird solemn attraction where they arch their drooping branches so as to form a "ghost-walk." Although it were superfluous to allude to their importance to archers of the past and present, it may not be generally known that "a paling-post of Yew will outlast a post of iron." From the millenarian Yew to the comparatively recent Araucaria is a bold transition, but one suggested by the same inward sense that too many of these Chilian strangers about a place impart a formality and solemn aspect to be deprecated. None who have seen can easily forget the magnificent specimen at Dropmore, its height some 53 feet, its girth at 3 feet from the ground 6 feet 4 inches, and its spread of branches 28 feet in diameter. There are others doing well, if not so well, by the waterside in the same paradise; but the good taste of Mr. Frost, the veteran gardener whose judgment has satisfied so many successive masters, evidently recoils from undue multiplication of trees of so eccentric a character. Their *raison d'être* must be by way of contrast, here and there one in a mixed company; but least of all are they a success in an avenue, the fine Cedar of Lebanon avenue at Dropmore being no precedent for a similar use of Araucarias. Cedars, whether of Lebanon or of India, have an impressiveness; in the one case from the habit of growth and the horizontal display of branches, in the other from a weeping grace and a refreshing evergreen brightness. But all evergreens, except perhaps the Scots Pine (which is commonly bare of stem, and which deserves a connection with avenues by reason of the tradition that the oldest of them now in existence were originally planted in secret sympathy with the cause

of the exiled Stuarts), must fail to possess the charm of deciduous trees—Elms, Beeches, or Oaks, for the composition of an avenue, to wit, the different guise of the trees in winter and summer in and out of leaf.

As timber in this country, neither of the later introductions promises to attain a higher rank than the Cedar of Lebanon—a tolerable second-class; though were it not of a soft fibre this last, from the girth of its best samples at Strathfieldsaye, Sion House, and Shobdon, ought to take a higher place. The Cedar at Shobdon has a circumference of 29 feet 4 inches.—(*Quarterly Review*.)

## NOTES ON VILLA AND SUBURBAN GARDENING.

**THE GREENHOUSE.**—At this advanced season of the year it must be borne in mind that all the necessary means for ripening the growths of hardwooded plants as quickly as possible must be adopted, for if deferred much later not so good a chance of bloom can be secured; and as winter approaches those plants that are growing ought to have more air and exposure to harden and prepare them for the hardships of winter, which sometimes prove very destructive to them.

There is very little potting required after this time, excepting such plants as Cinerarias, and even these but once more, for too late potting often proves a failure. Calceolarias and Primulas, too, must now have special attention, as their roots ought to be in full action. Shift into larger pots the earliest plants of these as they become ready. All plants mentioned will be better for being fumigated at different periods; but this operation is better done as soon as an insect is discovered, for if fumigation is delayed after that there will not only be twice the trouble in destroying the insects, but there is great risk of the plants being thrown into a bad state of health. All fresh plants when introduced to the house should be examined at once and fumigated before they affect others. This is the way to keep up a healthy and clean lot of plants, for several smokings after the plants are injured by insects is so much labour thrown away.

Chrysanthemums may still be shifted into larger pots if not already done, and apply liquid manure to such as have their pots full of roots, and which it is intended not to shift again. They must all be staked and tied-out neatly, and if necessary many of them may have a top-dressing of rich soil. This is one very effectual means of keeping the foliage well on at the bottom of the plants, which is so desirable and ornamental.

Mignonette for pots should be sown immediately and placed in a cold frame near the glass, and when the plants appear give them plenty of air and light, and have them thinned out as soon as large enough and kept growing as fast as possible. Tree Mignonette, which is a most ornamental plant, should have its last shift before the month is out. This always requires to be sown early in May to produce good plants by autumn. Some sow the seed as early as March, and of course get larger plants and earlier bloom than the others; they will produce flowers through the winter; they are amongst the most ornamental, as well as being sweet-scented, plants in cultivation.

Pot the tuberous-rooted Tropæolums in pots according to their size. They seldom require large pots, but the soil must be good yet not particularly rich. Loam and peat in equal proportions, and sand of the best quality added, with charcoal broken very fine and mixed well with the whole, will be found suitable. Good drainage must be secured. These plants do not like being repotted; therefore all things must be considered beforehand in such a way as to carry them through their flowering period most successfully.

As the stock of Japan Lilies go out of flower, ripen them off by laying the pots on their sides for a time before putting them away for the winter. The soil must not be allowed to become too dry, as the roots are very fleshy and should be ripened off gradually.

The plants of Amaryllis, which are now becoming dormant, must have attention. It is not a bad plan to shake them out of the soil and repot at once—that is, if they are in need of it. Potting once in two years is sufficient provided every precaution is taken at potting time to have the pots well drained. If the plants do not require potting a top-dressing must be given them. Some people do not pot them so often as I state if the plants are doing well; but the rule is, if potting is not done, to look to the drainage and renew it yearly, and surface-dress with rich compost, and to be careful that the bulbs ripen-off very gradually and well.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

We have sown Cauliflowers for planting-out in hand-lights and in boxes for spring use. Sowing earlier than the first or second week in September causes the plants to button in March or April. We sow the seeds in rows with the winter Onions; a

few seeds are mixed with the Onion seeds, and the Cauliflower plants are drawn out before they do any harm. Those who had put out plants in July will find them producing now, and they will continue to do so up to the end of October, according to the weather or district, whether it is early or backward. The hoe should be kept at work amongst all crops in the early stages of their growth, and when the plants are dry at the roots the earth may be drawn up round them in such a way that a shallow basin is formed, and when water is applied this holds it and causes it to go well into the ground near the roots.

It will now be time to earth-up Cardoons. The usual method is to tie the large leaves lightly together with haybands. The soil should be well broken-up and placed close to the plants as high as the bands. Other growers say, "Never earth-up Cardoons, but blanch them by tying the leaves closely together and thatching them over thickly with straw." The object in view is to blanch the leaves, and the best method is that which accomplishes this without causing them to rot. They last through the winter months and must be protected from damp and frost.

Spinach is a useful vegetable for the winter months. That which was sown last month will now require attention. Stirring the ground between the rows with the Dutch hoe encourages the growth of the plants; these should also be thinned-out by hand, and any weeds growing amongst them should also be pulled out. There is some danger of the kitchen garden being neglected at this season from weeds growing on the walks and borders and fallen leaves littering on the ground. All these should be swept or raked-up, and the weeds should be hand-picked from the walks.

We are still planting-out Coleworts on vacant ground. The early plants are put out about a foot apart, but so late as this 10 inches apart is sufficient. We begin cutting Coleworts early in November, and they are in use until the Sprouting Broccoli comes-in in the spring. Sprouting Broccoli and White Broccoli should also be planted-out now for the latest crops. It does best to be planted on hard ground, but it ought to have been well trenched and manured for the previous crop. Broccoli is a very good successional crop to Strawberries. These may be hoed-up; the ground should then be raked clean, and if it is very hard the Broccoli plants may be let in with a crowbar.

Lettuce intended to come into use in the spring may now be planted on a warm border where the plants are to remain during the winter. Seeds sown at once will also produce plants that are more likely to stand through the winter than those sown in August. Lettuce being so much esteemed as a salad, different plans may be tried to keep-up a succession through the winter months. Good-sized plants put out in a frame now will be sure to come in useful in November and December, and if the weather is mild they will improve in condition even in January. Sow seeds to produce a supply of small salading in drills under a south wall, or in any sheltered position.

#### PINES.

Plants, mostly Queens, intended to be forced very early next year have now attained their full development, and the house where they are growing is kept well ventilated and a night temperature of from 60° to 65° is provided. The plants receive only sufficient water to keep them in a healthy growing condition. The bottom heat for such plants ought not to exceed 85°. The varieties Charlotte Rothschild and Smooth-leaved Cayenne, which are now ripening their fruit, require a rather high temperature—from 65° to 70° at night will be suitable—with a rather dry atmosphere, and as much ventilation without exposing the plants to currents of cold air as possible. Succession plants which were potted early in August, and which are intended to fruit next summer, may be pushed forward with a temperature of 70° at night, or if it is up to 75° in warm nights no harm will be done. Close the house early in the afternoon, so that the sun heat may be utilised to keep up the temperature. A little air may be admitted at the top of the house early in the morning, even if the weather is dull and cold. This is quite as necessary as if it was bright and warm. Fresh air is the life and health of plants, and the longer a circulation of it can be kept up the better for the plants.

Suckers intended to produce fruit in 1878 need not be grown in a high temperature; there will be plenty of time for them to grow during next season. They should not be allowed to suffer for want of water at the roots, neither must too much water be given them. Watering Pines at the roots is an operation requiring great care; one man ought to have the entire charge of the watering, and it ought not to be trusted into other hands.

#### MELONS AND CUCUMBERS.

Melons have certainly been of very poor quality this year, and it is unlikely that they will improve now, but all that is possible ought to be done to bring the fruit up to the best flavour possible. It is little use to expect good fruit from frames after this time, and Melons ripening in heated houses ought to be exposed to light and air as much as possible. Lateral growth ought not to be encouraged. If the trelliswork is already covered with leaves all growth should be cut off that is not required, and this ought to be done before it is too hard. When it is left too long the

wounds at this season do not heal readily and decay sets in. 65° at night is a good temperature, with as much ventilation as possible without exposing the plants to cutting winds. Fruit ripening in dung frames should not lie on the ground but be elevated a little from it, but not so much as to expose the fruit to the sun. It ought to be shaded by the leaves to prevent scalding. As the fruit approaches the ripening stage it ought to be more exposed to the light.

Cucumbers in dung frames also require much attention at this season; a lining of hot manure or any fermenting material that would throw the heat into the body of the soil will be of much service in causing the plants to make growth. The more rapid that Cucumber plants grow the better is the produce. The frame ought not to be allowed to become crowded with growths, as the fruit in that case does not set well, is often mis-shapen, and otherwise of inferior quality. After this time Cucumbers are of the best quality when grown in heated houses and trained to a trellis near the glass. Should the leaves become infested with red spider they ought to be syringed every morning with clear water that has been standing in pots over the pipes through the previous night. Mildew is easily destroyed (if it is not allowed to spread to a serious extent) by dusting the affected parts with flowers of sulphur. The old growths ought to be cut out as much as possible, training the young shoots in the place of them. The night temperature should be 70°.

#### GREENHOUSE AND CONSERVATORY.

There is generally a difficulty with us in keeping up the display of flowers from this time until the Chrysanthemums come into flower. Zonal Pelargoniums and Fuchsias are the best soft-wooded plants for flowering at this season; there is also a very great variety, both of colour and form of flower, to be obtained from them. Amongst Fuchsias there are not only new varieties of the old florists' type in abundance, but some very ornamental and desirable species have been recently introduced. A new species with deep rich crimson-coloured flowers was exhibited by Mr. Cannell last week, *F. Boliviana*; the same exhibitor also sent a distinct variety with sub-erect flowers, and a variety of the florist type with a tinge of orange in the corolla. Mr. Laing of Stanstead Park has a hybrid of the *F. fulgens* type; and the pretty little species from Australia introduced by Mr. Kinghorn of Richmond, *F. procumbens*, is well adapted for small baskets or vases. Where a large quantity of flowers is required at this season the Fuchsia and Zonal Pelargonium are of great value.

Some hardwooded plants which have made more and stronger growth than it was expected of them will still require to be repotted. This work must not be longer delayed. I well remember potting a number of hardwooded greenhouse plants in October. It was north of the Forth, where the sun does not have much power, and the plants did not root into the new material as was expected, the result being that some of them died during the winter. The others received a check, which they did not overcome for a season or two. Of course it was natural to suppose that this would be the case even if the watering had been done in the most careful manner. It was not possible to prevent the fresh soil from becoming sodden when there were not roots to absorb the moisture from it. The roots are sufficiently active at present to start into growth at once; but repotting ought to be seen to without delay. Some hardwooded plants are very liable to the attacks of mildew, others become infested with red spider. Both are insidious enemies, and must be watched for with the utmost vigilance. Some plants which are liable to the attacks of red spider are syringed every day; of these may be named the different species of *Boronia*, *Pimeleas*, and *Statice*. When mildew attacks a plant badly a good plan is to lay it on its side with a newspaper spread out under it, then thoroughly dust the plant with flowers of sulphur. Let it be turned over so that the upper and under sides of the leaves are quite powdered. When the operation is finished gently shake the plant to free it from superfluous sulphur, and that which falls on the paper can be saved and used at another time. Care must be taken to prevent a large portion of the sulphur from falling into the pot. Much of it sadly injures the roots of some plants.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

Dick Radclyffe & Co., 129, High Holborn, London.—*Catalogue of Bulbs, Seeds, and Horticultural Decorations.*  
Hooper & Co., Covent Garden Market, London.—*Catalogue of Bulbs, Spring Flowers, Seeds, and Fruit Trees.*  
Stephen Brown, Weston-super-Mare, Somerset.—*Autumn Catalogue of Bulbs and Flower Roots.*  
Barr & Sugden, 12, King Street, Covent Garden, London, W.C.—*Catalogue of Bulbs and Plants.*  
S. Dixon & Co., 34, Moorgate Street, City, London.—*Catalogue of Dutch and other Flower Roots.*  
Edmondson Brothers, 10, Dame Street, Dublin.—*Autumn Catalogue of Dutch Bulbs, Gladioli, &c.*  
James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Dutch Flower Roots, Seeds, and Garden Requisites.*

Messrs. Daniel Bros., The Royal Norfolk Seed Establishment, Norwich.—*Illustrated Catalogue of Dutch Flower Roots.*

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

IPSWICH. September 17th. Sec. Mr. W. B. Jeffries, Henley Road, Ipswich.  
NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.  
LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

ORNAMENTAL GRASS (*G. Diss.*).—Your specimen is *Stipa pennata*, Feather Grass. It is a perennial, native of Great Britain.

DWARF KIDNEY BEAN (*W. H. O.*).—It seems to be similar to the Dwarf White Dutch. Its pale colour is not a recommendation, for bright green is desired by cooks.

SEEDLING BEGONIAS (*J. P.*).—The flowers sent, which have been produced by plants raised from seed sown in February, are large in size and good in colour. If the plants possess good habits and are floriferous, the varieties are worthy of preservation and increase.

LOBELIAS FOR EARLY FLOWERING (*S. J.*).—Sow the seed at once in light soil, keeping moist, and place in a close frame. If you water the soil previous to sowing the seed, and cover with a square of glass, and keep dark for a week or until the seed germinates, you will not have occasion to cover the seed with soil or sand. The seedlings may remain in the pot or box throughout the winter, pricking them off early in spring. The plants will be some weeks earlier than plants from seed sown in spring.

ROSE SEED AND CUTTINGS (*J. Turtle*).—We do not know of any seedsman or florist who sells them. You must apply to your amateur friends. In propagating by seed Mr. Macintosh says—"The seed vessels should be left on the trees until they are perfectly ripened, at which time the skin of the hip or vessel becomes almost black. They should then be placed in small pots embedded in sand, and each sort kept separate, and buried underground till spring. About the beginning of February is a good time to prepare for sowing; at which time the seed pods should be taken out of the pots and rubbed between the hands until the seed becomes separated from the pulp and skin. They should then be sown in pots or pans, in light loamy soil, and, when watered, covered to the depth of half an inch with the same compost mixed with a little sand. They may then be placed in a cool pit or frame, or plunged at the bottom of a wall, and kept in a uniform state of moisture. The plants will appear during summer, and be fit for transplanting the following spring. Many of the seeds will not vegetate the first year, therefore those which remain dormant should be picked out when the young plants are removed and resown, when they will, for the most part, vegetate during the following season. Some of the autumnal varieties will flower the first year, but none of the summer sorts will do so till the second, third, or fourth year. The young plants require shading during hot sunshine, and a regular supply of water, as they are liable to suffer from an excess of the one or a deficiency of the other. As soon as the seedlings have formed their second leaves they are fit for transplanting; their removal, however, must take place with a due amount of care, lest the seeds just germinating be injured by the operation."

NEW BEGONIAS.—Messrs. E. & J. Perkins inform us that first certificates were awarded for Excellent and Majesticum by the Royal Horticultural Society. These fine plants and varieties were noticed in our report of the meeting.

DAHLIA EARL OF BEACONSFIELD was exhibited by Mr. G. Rawlings, Romford, and not by Mr. Turner, as inadvertently stated in our report of the Floral Committee's meeting. It had a first-class certificate awarded.

VINES NOT GROWING (*Ted*).—It is probably because the roots were not disentangled when they were planted. We advise you to disentangle the roots, plant afresh, and treat the vines according to instructions given in this Journal. Paraffin or boiled oil, either of them applied with a small brush, will destroy American blight.

STRAWBERRIES FOR SANDY SOIL (*Weston*).—It is unsuitable for Strawberries, and good fruit can only be obtained on it by careful watering and surface-mulching. Vicomtesse Hericart de Thury, Myatt's Eliza, President, Sir Charles Napier, Sir Joseph Paxton, and Dr. Hogg are as suitable as any.

IRISH PEACH APPLE (*Dorset*).—This is one of the most valuable of early dessert Apples, ripening in August. You should certainly add it to your collection. See "WILTSHIRE RECTOR'S" estimate of this Apple in another column.

PERENNIAL ASTERS (*Wimbledon*).—You can obtain plants from nurserymen and florists who deal in hardy flowers. Notes on their cultivation and a list of sorts are in N. 778, the issue of February 24th of the present year.

VARIOUS (*J. Rhodes*).—We should remove the surface soil and add fresh to the bronze Pelargoniums, and repot them when commencing fresh growth in the spring. Snowflake is a kidney Potato, but any tubers which are perfectly round would not, we think, be disqualified in the round classes. Red spider may be prevented by regularly syringing your Cucumbers next year. The Victoria and Quilled Asters are suitable for exhibition.

HEATING A SMALL GREENHOUSE (*S. S.*).—You do not state the size, construction, or any particulars as to site of your greenhouse. You will find what you require by consulting our advertising columns, selecting either a stove or hot-water apparatus as is most suitable to your requirements and circumstances.

LARGE GRAPES (*Amateur*).—The largest black Grape is Gros Colman, but it requires heat to produce it of good flavour; and the largest white Grape is Duke of Buccleuch, a very sweet and juicy variety, ripening within the same house as the Black Hamburg. Several cultivators, however, have failed to produce good crops of "the Duke," while others have succeeded well in growing it. We should be glad to have information from those who have grown this variety.

HYACINTHS FOR EXHIBITION (*West London*).—Some of the finest varieties are the following:—*Whites*: La Grandesse, L'Innocence, Mont Blanc, Paix de l'Europe, Alba maxima, and Madame Van der Hoop. *Blues*: King of the Blues, Argus, Baron Van Tuyl, Czar Peter, General Havelock, and Princess Mary of Cambridge. *Reds*: Garibaldi, Vurbaak, Prince Albert Victor, Lord Macanlay, General Feliassier, and Von Schiller. *Yellows*: Obelisque and Bird of Paradise.

TULIPS FOR EXHIBITION (*Idem*).—Chrysolora, Proserpine, Vermillion Brilliant, White Pottebakker, Keyserkroon, Joost Van Vondel, Queen of Violets, and Roi Pepin.

FRUIT TREES LUXURIANT (*T. S., Bradford*).—You may cut out at once all exuberant and crowded growths, not leaving them until the winter pruning. Possibly your trees may require root-pruning for cutting-back luxuriant shoots severely and leaving the roots unchecked, is only preparing for similar and possibly still stronger wood being produced next season.

PEACHES INSIPID (*Reader*).—It is not the characteristic of Peaches grown in pots and in the full sunshine under glass to be of inferior flavour, and 15 to 18-inch pots are quite large enough for the trees. We generally have them of superior flavour, but this season they are not so good as usual, but they are certainly as good as they are grown on the open walls or in Peach cases. We believe the feeding with manure water, and, perhaps, giving the trees too much of it, is the reason. We never give manure water, preferring to supply extra nourishment from surface-dressings. We also advise you to omit the bones in potting. Water must be given more sparingly when the fruit is swelling-off.

MANAGEMENT OF PINES (*An Older Subscriber*).—You will find full instructions by referring to "Doings of the Last Week" in our back numbers. You should now plunge the pots in a bottom heat of not more than 85°. Keep the plants moderately dry at the roots, with a night temperature of from 60° to 65°. Admit air as freely as possible, and let the atmosphere be rather dry. Watch for future information in the "Doings."

PEACH TREES ON BACK WALL OF VINERY (*W. Hartley*).—As you will have 6 feet width of border outside, the same inside width will be sufficient. This will give 7 feet 6 inches for the Peach trees. A 4½-inch wall set in mortar will not prevent the roots from going through it, but if it is well set in cement the object will be attained. We ought to inform you that you cannot grow Peaches successfully under the shade of Vines.

SEEDLING GERANIUMS (*H. Cannell*).—The flowers are very distinctly striped, but no one can give an opinion on their merits from single tips.

WINTERING GERANIUMS AND CALCEOLARIAS (*A Reader*).—We should not have put in the Calceolaria cuttings until the early part of October, for which your cold pit would answer admirably. There will not be any necessity to remove any of the dung and soil used for the Cucumbers, but seeing that the soil is in a thoroughly moist state, cover it with an inch of sand, and put in the cuttings in rows 2½ inches apart and 2 inches between the cuttings, giving a good watering after insertion. The lights may be put on, but we leave ours off until frost, it being important that the cuttings be kept cool. Keep off heavy rains, and give air whenever the weather is favourable. Protection should be given from frost; mats and straw placed over the lights and some litter placed against the sides will suffice, neither of which should be removed so long as frosts prevail, but in all mild weather the Calceolarias cannot have too much air. We should have the Geraniums potted or put into boxes so soon as rooted, and winter them in the house windows. It is very unlikely that you will succeed in wintering them in a frame. The cuttings may be put in rather thickly in the pots or boxes, and in spring be potted-off singly and grown-on in the frame after the Calceolarias are planted out, as they may be after the middle of March, affording them a slight protection from frosts.

WINTERING BEDDING PLANTS (*X. Y. Z.*).—You might be able to winter Calceolarias in a frame made out of the old window lights, but you have no chance of preserving Geraniums and Heliotropes over the winter with no room for them indoors. Surely you have windows. The plants taken up and potted would succeed admirably if kept rather dry, the large leaves being removed from the Geraniums. The Erythrina Cristagalli will require to be taken up after the first frost, and the top being cut away the roots may be kept in sand in a place safe from frost. Fuchsias, after their leaves have fallen, may be wintered in any place light or dark which is safe from frost; they require very little water when thus preserved.

MINERAL OIL STOVES (*T. F. K.*).—We have no experience of their use. Write to the vendor for references to those who have used them. One thing is certain, no fuel can be burned without injury to the plants in a greenhouse unless the fumes are conveyed by a chimney into the outer air.

WINTERING ECHEVERIAS (*Mr. Owen*).—They are half-hardy, requiring to be taken up before frost and potted in rather poor loamy soil, and kept rather dry over the winter in a light airy position in a greenhouse safe from frost, or they may be wintered safely in a room window.

DIELYTRA SPECTABILIS AND SPIREA JAPONICA (*Idem*).—Both succeed admirably grown in pots, and are very fine. Take up the plants after the foliage dies down and pot them, plunging the plants over the pots an inch or two in ashes, and remove to the greenhouse or house after Christmas.

LATE DESSERT APPLES (*Idem*).—Bradrick's Nonpareil, Court Pendu Plat, Lamb Abbey Pearmain, Reinette du Canada, Sykehouse Russet, and Sturmer Pippin.

NAME OF FIG (*W. K.*).—We could not name an imperfect fruit without the aid of leaves.

INSECTS ON PEACH TREES (*Idem*).—If the dirty-looking insect is aphid it may be destroyed by fumigating. You had better not burn sulphur on the gravel paths.

NAME OF TREE (*Schubert*).—We cannot name any plant from leaves only.

NAMES OF PLANTS (*F. E. H.*).—It is *Woodwardia radicans*, and is, perhaps, kept in a temperature unsuitable. We cannot name plants from leaves only. (*W. H. O.*)—*Asclepias curassavica*. (*Snagdragon*).—The blue flower is *Polemonium reptans*. We cannot name florist's varieties. (*E. O. T.*)—*Funkia ovata*. (*P. Edwards*).—Cannot name from fragment sent. (*W. D.*)—1, Perhaps *Costmary* (*Tanacetum Balsamita*); 3, *Sneezewort* (*Achillea Ptarmica*); 4, *Mentha rotundifolia*. Specimens bad. (*F. P.*)—*Lastrea dilatata*. (*Ecce*).—1, *Sedum spectabile*; 2, *Symphoricarpos racemosus*, St. Peter's-wort, and known also as the Snowberry. It is a hardy deciduous shrub from North America. Your post-box is simple and effectual, a pattern of its kind.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### THE PORTSMOUTH POULTRY SHOW.

WE mentioned a week or two back that the Portsmouth Committee were doing all in their power to make wrong right, and we wondered what shape the indulgence they asked for would take. Before the lines were printed almost the secret had transpired, and the "little indulgence from the exhibitors" is 10s. in the pound. We do not call it a little one, but a gigantic one, and one we hope exhibitors will not agree with at all. In the little epistle which accompanies the balance sheet the Committee generously state that "it would have been much more satisfactory to them could they have paid in full." We concur, and expect even now that many will insist upon full payment, notwithstanding the balance sheet and the £290 13s. 4d. We quite think the time has come to investigate the principles upon which these erring exhibitions work, and we hope exhibitors will themselves take up the subject, for after all the matter is only of importance to them. About this Show we have had letters from all sides speaking in the strongest terms, and we really do not wonder at the anger displayed in them.

The balance sheet is very mystifying, and we could ask copious questions about it. We are quite sure all will have asked themselves the same queries, but for the benefit of those who were not prizetakers we will ask them here. (1), In the expenditure column £54 we read has been spent in prize money. We ask, Was this paid in full, and why have some been paid and not others? (2), We read judges' fees and expenses came to £27 16s. as if they were paid, when we believe we are correct in stating that the expenses of one of the poultry judges had not been paid on September 1st. (3), Judges' dinner and refreshments came to £22 7s. 8d. Is it possible they can have partaken so heartily? or did they have a banquet? (4), Nine silver cups and hire of plate came to £25 12s. 6d. Does this include the cost of all the plate? If so, we know of one gentleman who has never received his cup, and we again ask, Why should some have done so and not others? (5), We find the balance to the bad is put down at £290 13s. 4d., but this £117 10s. 9d. was the debt of the past year, and it does seem monstrous to try and make exhibitors on this occasion pay debts contracted by the Committee in past times. It really looks as if this last event had been got up merely as a speculation, something like the Birmingham Summer Show affair, with a "sink or swim" sort of feeling. It surely was wrong for a show so much to the bad to incur the fresh risks of another exhibition, and having done so to try and get their exhibitors to make up their debts. We are sure the Committee will get no sympathy, for even on the day when the public had to pay 6s. each to go in and see the judging, not one of the officers seemed the least anxious for the welfare of their visitors, as nothing could draw out from them the winning numbers in the various classes, their thoughts seemingly being entirely concentrated upon the banquet which was to come off later on. We should be glad to hear what exhibitors mean to do in the matter. We will support them in every way, and we know of some who mean to put the matter into the County Court. Anyhow, we would beg that no one should agree to take less than their dues until matters have become more arranged, for we do not see why this Show, like the Aston Park *fiasco*, should get into the difficulty it has done and out again so easily. We are assured that some of the Committee are in a position to pay the debts, and we do not see why their supporters, who went to great expense in entrance fees and carriage, should only be the losers.

To give an idea of what fanciers think of this affair, we will quote from one or two letters. One exhibitor says it cost him £7 sending to and entering at the Show, and he writes, "It is quite time these wrong doings were put an end to—this last affair has made the cup run over." Another writes, "It is the coolest document I ever read. I have represented that cups are put down in the expenditure, and that I have never received mine. Could not you expose the proceedings in the Journal?" While another writes, "My reply to their disgraceful circular was that I had not the least intention of accepting 10s. in the pound. Had the Committee not guaranteed payment within fourteen days I should have acted very differently, but under the circumstances and owing to the incivility of the Secretary not replying to several letters I feel indisposed at this late date to

accept their offer. At any other show not casting abroad such 'baits' I should pity them, and accept such an offer." We could quote from many more, but we have shown the opinions of three of our largest exhibitors, and we believe nearly every other one agrees with them. We say, then, let the matter be clearly settled once for all, so as to know whether committees can do as Portsmouth wishes to do, and come out of the affair as pleasantly as they commenced it.—W.

## ABANDONMENT OF THE ALEXANDRA PALACE POULTRY AND PIGEON EXHIBITION.

YOU will doubtless have seen Mr. Tegetmeier's announcement of the abandonment of the Alexandra Show, but we feel that your readers and the whole of the breeders and exhibitors throughout the kingdom should be furnished with full particulars of this lamentable *fiasco*, in order that they may know where the real blame lies.

You are aware that we as Secretaries, with Mr. Tegetmeier as Treasurer, carried out the Poultry and Pigeon Show last October, and the Cat and Rabbit Show in the spring of the present year, and we flatter ourselves that the mode in which these two shows were conducted was such as to earn the approval of the bulk of our exhibitors, and we have reason to know that the authorities at the Palace were satisfied with our arrangements. It is also perfectly clear from the many and kind expressions of good will and promises of support we had received from exhibitors in every direction that the Show announced to take place in October would have proved a triumphant success, and we deeply regret that circumstances over which we had not the slightest control have prevented its being carried out.

In anticipation of the Show, and in connection therewith, so long ago as March last an interview took place between Mr. Tegetmeier and one of the chief members of the executive staff of the Palace, the result of which was that after corresponding with secretaries of some other shows, the date of the Alexandra Show was fixed and duly announced in the poultry papers, and from that time we have been actively engaged in the necessary arrangements for carrying out the Show, and that the authorities at the Palace were fully aware of our movements is evident from the fact that, in consequence of our having no permanent office in London, a large number of letters have during the last two or three months reached our hands through the Alexandra Palace, having been addressed to us there by the writers, and forwarded to us day by day by the Palace officials. Yet, in spite of all this, at the eleventh hour, when all our preliminary arrangements were completed, and without our having received the slightest previous intimation of even the probability of such a thing occurring, on the 25th August Mr. Tegetmeier received from the Palace a telegram to the following effect—"There will be no Poultry Show this year. See me as soon as possible." Of course no time was lost in placing ourselves in communication with the authorities at the Palace, as we could only imagine there must be some mistake, not thinking it possible that such a thing could happen. Nothing definite, however, could be done until the meeting of the Board of Directors on August 31st, but from what transpired during the interval we were justified in hoping that the catastrophe would be averted, and that the Show would yet take place. When the Board met, without affording us any satisfactory reason for their course of action, and entirely ignoring the arrangements entered into with their officials, they determined, owing, we believe, to some radical change in their policy, that no Shows whatever were to be held this year. It was in vain that it was represented to them that we had been at work for months on the Show, that we had incurred considerable expense and serious responsibilities, that we had engaged eight gentlemen from various parts of the country to act as Judges, that offices were rented for which we have now no use whatever, that our schedule was in type all ready for issue, that we had two or three thousand postage wrappers already addressed, besides a large quantity of stationery and envelopes stamped and printed for our use, and that as men of honour we should be seriously compromised if we were unable to keep faith with the public and those friends who had so kindly promised us their assistance and support. Nothing would move them for their determination. We offered to forego any pecuniary arrangement we had made with them, and to carry on the Show at our own personal risk and responsibility, and to submit to any sacrifice rather than suffer the Show to collapse. All this had no effect, and we are therefore in our defence compelled to lay before your readers this plain statement of facts, and of what we cannot help feeling to be very bad and disgraceful treatment, which is to us perfectly incomprehensible.

With regard to our legal position in the matter, of that for obvious reasons we say nothing, and only trust that our friends, among whom we hope are included all the fanciers in the kingdom, will absolve us from all blame in the matter, and give us credit for having done all in our power to avert the abandonment of that which we had hoped and had good reason to believe would have proved a most successful exhibition, the loss of

which must prove a great disappointment to many hundreds of fanciers and exhibitors. We beg to tender our sincere and hearty thanks to those amateurs and exhibitors who had so kindly promised cups, subscriptions, and entries, to whom we hope to write individually in the course of a few days.—P. H. JONES, W. J. NICHOLS, 37, Farringdon Street, London, E.C.

### POULTRY AND BEE NEWS AND QUERIES.

THE Committee of the Leghorn Club have sent us one of their little pamphlets containing their rules and the standard of excellence. The former seem very carefully made, and that on trimming, No. 5, is very sensible. We read, too, that they propose to have honorary members (confined to non-exhibitors of Leghorns), which are to be elected at the discretion of the Committee. We approve of this, and hope it may lead to the fanciers of other breeds also following the example of their Leghorn friends, and so starting a club for themselves. We have often noticed that many of the cocks of this breed are very high in tail, which detracts from the graceful carriage of the birds; but we read in this new standard of excellence that "a squirrel tail is a disqualification." From what we have seen this year of chickens of the two colours we think size and colour of the earlobes are two of the most necessary points to breed for.

There seems to have been a perfect *bouleversement* among old-fashioned poultry exhibitions. We learn with much regret that the Alexandra Palace Show will not come off, but we hope the Committee will look out some place in London and so be able to hold an exhibition later on. The old-established mother Show, Birmingham, has pushed on her dates two or three weeks, and the Show will this year be held in the middle of December. Mr. Cambridge has arranged to have his annual reunion on December 1st, 2nd, and 4th. We believe Salisbury intends to hold a county Show, and will probably step into the date vacated by Bristol; while Oxford, alone so far, is setting to work with a grander schedule than ever, for the last Wednesday and Thursday in October as usual. The Crystal Palace dates we have not heard, neither do we know if Mr. Jennison holds his meeting this year in the Belle Vue Gardens, Manchester.

The Weymouth prize money was paid within eight days of the closing of the Show. It is a pity Portsmouth and Bournemouth did not do as well. It makes exhibitors look askew at those "monthly" towns; but we knew Weymouth would be up to the mark from the business-like way they moved from the beginning.

We are again requested to state that the new Ipswich Show has no connection with the old one. By-the-by, we see the date of the latter is now changed to November 23rd, while the Judges of the former are announced as Messrs. Hewitt, Teebay, Hutton, and J. Martin.

We have been favoured with a proof copy of the Oxford schedule, and can thoroughly recommend all fanciers to send for a copy. We hope to review it later on. The Pigeon classes are very numerous, and we hear there are altogether fifty-six cups or pieces of plate to be awarded in prizes. The Judges are to be the same as those in former years.—W.

### DERBYSHIRE SHOW OF POULTRY, &c.

THE annual meeting of the Derbyshire Agricultural Society was held on the 5th and 6th inst. Poultry and Pigeons were placed under two large tents, plenty of room being left for the accommodation of visitors. The pens were of wood with wire fronts, but these were particularly clean and well whitewashed. The poultry were all young except the Selling class, which was for any age.

*Dorkings* were a good lot. First Dark Greys, but the cock a little short of colour; second Silvers, in which pen the pullet was a very good one. *Spanish*, first very good, rest moderate. In *Game* was one grand pen of Brown Reds, to which the cup was awarded; second Black Reds, the pullet not as good, but cock smart; third Black Reds, very young. Any other variety, first Piles and second Duckwings. With the exception of the winners the *Hamburghs* were poor, but the second-prize Gold-pencil pullet was particularly good, the cockerel poor. *Cochins*, Buff poor, but the others better, the cup going to a good pair of Partridge. *Brahmas*, Light, a moderate lot, the cup going to the first pen, but the cockerel is too thin-bodied, the Dark not being as evenly matched. Black *Hamburghs* won in the Variety class, with *Houdans* second. The Selling class was a good one, as may be seen when we say a highly commended pen of *Brahma* chickens was better than the winning pen in the *Brahma* class, the first being Black *Hamburghs*, second Partridge *Cochins*, and third Booted Bantams. *Ducks* in both classes were very good, but several pens looked too old for this season's hatch, and must have been sent in mistake. *Geese* very fine.

*Pigeons* had a few classes. Carriers a good entry, but only about four good birds. *Dragoons* bad except the winners.

*Tumblers* very good. First a capital Almond hen, second a cock, and very highly commended an Almond cock also. *Fantails* a very large and good class, the winners white. *Turbits*, a very pretty Silver hen first, and second also Silver. The Variety class good and large. First a Black Barb hen, second a Silver Owl, third a Black Barb cock, and extra third a Red Chequer Antwerp. The first in the Selling class was a good Silver *Dragon*, a Blue *Turbit* second, many others being noticed.

**POULTRY.**—*DORKINGS*.—1, F. S. Arkwright. 2, Hon. Mrs. Colville. 3, Dr. Snell. *SPANISH*.—1 and 2, S. W. Hallam. 3, W. Good. *GAME*.—Black or Brown-breasted Red.—1, T. B. Lowe. 2, T. Cook. 3, W. Cox. Any other variety. 1, G. Barnesby. 2, E. Winwood. 3, G. Lucas. *HAMBURGHS*.—Gold or Silver-pencilled.—1, G. Ashpole. 2, S. W. Hallam. 3, C. Pickering. Gold or Silver-spangled.—1, S. W. Hallam. 2, G. Meynell. 3, C. Pickering. *COCHINS*.—Buff or Cinnamon.—1, Rev. R. Feilden. 2, Mrs. Radford. 3, E. Toon. Any other variety.—1, Rev. R. Feilden. 2 and 3, Rev. L. Storer. *BRAHMA POOPAS*.—Light.—1, A. S. Webb. 2, F. Holbrook. 3, Dr. Snell. Dark.—1, E. Pritchard. 2 and 3, F. Holbrook. ANY OTHER VARIETY.—1, Rev. A. S. Webb. 2, Sherwin. 3, F. Holbrook. *CROSS-BRED*.—1, S. W. Hallam. 2, S. E. Vernon. *SELLING CLASS*.—1, D. Lewis. 2, Rev. R. Feilden. 3, F. Holbrook. *DUCKS*.—*HOUENS*.—1, Dr. Snell. 2, C. Pickering. 3, Sherwin. *AGLESBURY*.—1, Dr. Snell. 2, J. Denson. 3, W. H. Crewe. *GESE*.—1, Hon. Mrs. Colville. 2, Dr. Snell. 3, R. Johnson. *TURKEYS*.—1, W. Cox.

Holbrook. *TURBITS*.—1, H. Yardley. 2, J. Wood. ANY OTHER VARIETY.—1 and 3, H. Yardley. 2, H. Parker. Extra 3, G. Dumble. *SELLING CLASS*.—1, W. Woolley, jun. 2, J. Wood.

The Judges were the Rev. G. F. Hodgson and Mr. E. Hutton.

### BATH POULTRY SHOW.

THIS Exhibition was held in large tents in the College grounds on the 6th and 7th inst. The quality of the birds was very good, especially in the *Dorkings*, *Cochins*, and *French*. Rev. G. F. Hodgson awarded the poultry prizes, while Mr. Tegetmeier officiated over the Pigeons. We heard of very few complaints, although each Judge must have had his hands full.

In *Dorking* cockerels the first won the champion cock cup. He is a brave bird, with more growth in him yet, and very perfect in feet. The first pullet was very fine, large in frame, and very fair in colour. In Silver cockerels the first was very forward in plumage, and won easily; second went to a pretty White, good in colour but a little faulty in toes; while the third went to a fine young bird with much growth apparently in store. In pullets the winners were very forward and good in colour. In Buff *Cochin* cockerels the first-prize bird was large and well grown, but he was not quite our style for colour. In pullets the first was very large and well shown; she won the champion hen cup, and we think on the whole she deserved it. In White pullets the first was in deep moult, and her pen was full of feathers. We certainly preferred the third-prize bird. In cockerels the first was very bad in colour, and we did not like the award. The second will perhaps make up well, but he appeared to us to be knock-kneed. In Partridge pullets the first was well pencilled; the second very dark, but charming in shape and fluff. *Brahmas*, Dark, made only a moderate display. The cockerels were certainly poor, the first decidedly the best, but loose in comb. In pullets the first was the bird we saw in the Malmesbury sale class, and she is still in the same owner's hands. In Light cockerels the first was large, and must have been early. In pullets the first is the best bird we have yet seen; she is good in colour and points, and above all has large size. The second was also good and clear in hackles; the third large, but not so distinct in the neck markings. In *Hamburghs* the first cockerel in Pencils went to a pretty Silver, while in pullets a very good Golden was first, and the second almost her equal. The first Silver-spangled had a very good tail, and was generally well marked. The Blacks were very good, and we fancy the chickens have been so far more glossy than usual. In *Malays* the first cockerel was large and in light feather, while in pullets we liked the winner immensely. She is a perfect bird for style, and will make, we think, a very large hen. In the *Spanish* we liked the second pullet best. She had more quality in face, and seemed a smarter bird. In *Houdans* a wonderfully good bird won the cup. He was the Alford first-prize bird, and is of a good dark colour, with a beautiful leaf comb. The first pullet was a little too white in crest for our taste. In *Crêves* the first-prize cockerel was very lustrous and fairly large, while the same exhibitor's first pullet was very big indeed, but of not so good colour as the second. *Silkie*s formed a pretty collection, and found many admiring spectators. The first pair contained a full-crested cockerel, but we fear when he is older his comb will be red, and that he will be too large. In the Ornamental class *Sultans* won first, and Gold Pheasants the other two prizes. Of course *Sultans* are ornamental, but so are *Cochins*, and so are hosts of other breeds, and we do not see *Sultans* had any right to be in the class. In the Variety cockerel class a very beautiful White-crested Poland won first, and a nice Golden second, while in the next class the two varieties, both very good specimens of their kinds, changed places. *Leghorns* were rather disappointing; the first Whites were forward and clean. In Browns the first cockerel was a good colour, and so was the second pullet. In *Game Bantams* the winner was a stylish bird with neat head, and in the variety Bantam class a

### PARASITES IN BIRD CAGES.

IN order to protect our Canary birds from the little red parasite various means are employed, principal among which is the Persian insect powder, although I have never found this article of much use. I have now discovered another excellent remedy, which, if rightly applied, banishes the insects forthwith. This is a tea made from quassia. It is made by pouring one pint of boiling water over one-half ounce of quassia. With this tea the walls of the cages, nesting places, roosts, &c., should be thoroughly washed, letting the liquid run into all the cracks, however small. If this is done often no insects will ever appear.—W. G. TODD.—(*Pet Stock Bulletin*.)

### FEEDING-UP RESCUED BEES.

A CORRESPONDENT writes as follows—"I have two heavy straw hives filled with worker combs by swarms of this year, and I wish to drive these bees, extract the honey, add the combs to a partially-filled frame hive, return the driven bees to their straw hives, and so feed them as to induce them to refill their dwelling with worker combs. Can I be certain of attaining this latter purpose at this time of year by gentle continuous feeding?" To this letter I purpose to append a few thoughts which have been floating in my mind for some days, which may be suggestive to many bee-keepers, as well as to our correspondent in particular, at this time of year.

First an answer to the direct question must be given in the negative. Bees will not confine their attention at this time of year to the building of worker combs so as to fill an empty hive with them, because, come what will, they never breed in autumn as they do in spring and summer time unless fed with great continuity and liberality. Gentle continuous feeding will induce the queen to breed moderately, and the bees will supply her wants with sufficient worker comb, and no more. If the supply of food be liberal they will lengthen out their cells all round the centre breeding nest and seal it up; if very liberally fed they will breed drone comb quite as often as worker comb, and treat it in the same manner.

If our correspondent would add in each case to the two hives he is anxious to feed-up one or more lots of bees saved from among the surrounding cottage apiaries, the increased population thereby gained would induce a larger building of worker comb, as the queen would find so much more opportunity for laying in the increased space that would be heated by the presence of so many more bees, for more comb would be covered by them; but with merely the returned population of his two hives but little brood could come to maturity now that the nights are longer and colder. Anyhow, let him be careful, by narrowed entrances and proper shelter and warm covering, to maintain as high a temperature as possible within the hives.

It is to be hoped that many bee-keepers will be induced to follow his example as to the plundering of the swarms of this year. Indeed, it is only swarms of the current year that are at any time worth taking up; and be it remembered that these always have the old queens, which in not a few cases are all but superannuated. Old hives, heavy as they weigh, contain at least as much brood and pollen and dirt as they do honey, and the latter must needs become deteriorated in value during the process of extraction from the more or less blackened combs. Two-thirds of waste must in most cases be allowed in calculating profits with old hives. I prefer to let such remain from year to year till the combs become too old and contracted for profitable use.

By all means "add the worker combs to a partially-filled frame hive." I have been doing this very thing last week to a swarm of this spring in a Woodbury hive, from which I had taken several beautiful combs filled with honey. The combs were taken from a common straw skep, cut to shape and fitted into the frames with a few cross pieces of thin lath tacked over the comb to the frame sides. These will be removed in due time. For all Mr. Pettigrew's deprecatory observations touching these bar-frame hives, nobody who has given them a fair trial and has used them efficiently will be found to give them up, so easy is it to examine every comb and to adjust the combs to the wants of the hive and the aims of the bee-master. They are simplicity itself, and give the most perfect command of the apiary to an intelligent person. My Woodburies have narrow strips of wood, unfastened instead of secured top-boards. By removing these one after the other, only so much of the hive is exposed to view as is to be dealt with. A few whiffs of smoke

dislodge or quiet the exposed bees, which, however, are generally too astonished at the sudden invasion of light to move at all in any irritated manner. To remove a comb when properly made or adjusted within the frame is an easy matter, so also is it to replace it.

I cannot conclude without asking our correspondent why he does not make up all his hives as bar-frame hives, and give his bees to them instead of returning them to his straw skeps. There are plenty of valuable empty worker combs to be had for the asking among country bee-keepers. The adjustment of these in bar-frame hives would be far more profitable and satisfactory in every way than trying to fill his straw hives this autumn.—B. & W.

### COMPLETING UNFINISHED SUPERS.

YOUR correspondent "O. B.'s" remarks in page 225 have the direct tendency to mislead the young bee-keeper, the very thing he sets forth to avoid.

I am not aware that the common practice in large apiaries of transferring an uncompleted super from a newly swarmed to an unswarmed stock has as yet been called in question, and the bee-keeper would be young indeed who did not see the propriety of adopting it.

Your correspondent's stipulation of the transfer taking place "during the honey harvest" is beside the mark, as Mr. Pettigrew distinctly recommends, at page 19, his artificial super manufacture to be begun "at the end of the season."

Of administering feeding for the completion of supers at either period, my experience is simply nil; but the novice might be reminded that, however readily bees may step into the labours of their predecessors and complete the work in their unbroken combs during the honey flow at the end of the season when thieving is rife, the odour and leakage inseparable from the all-round-bleeding borders of each comb proposed to be inserted into the artificial supers, the robbers, "scenting the carrion from afar," would most probably vie with the inmates of the hive on which they were placed to appropriate the treasure trove. At all events I do think Mr. Hunter's detailed experience is more in keeping with the common practice of bees than Mr. Pettigrew's questionable theory.

In my remarks in last week's issue on "The Stewarton Hive and System," my strongest colony stocked with first cross Italians, by a typographical error is converted into "first-class" Italians.—A RENFREWSHIRE BEE-KEEPER.

### DO BEES GATHER HONEY OR MAKE IT?

PROF. RILEY, the entomologist, at a recent housekeepers' convention in St. Louis, stated that bees do not extract honey ready made from flowers, but make it. The nectar lying in the flowers, says the Professor, could never be manufactured into honey, no matter how manipulated by man; but it is taken up by the bees and passed through a state of semi-digestion and excretion, resulting in honey, yet still retaining in part the flavour or perfume of the flowers from which the nectar has been extracted, by which we determine one kind of honey from another. This view has since been corroborated by a chemist and botanist of Louisiana, who described the changes undergone by nectar in its elaboration into honey in the bee's stomach. At the same meeting Prof. Riley intimated in reply to the query, Do bees injure fruit? that they do, but only in seasons of severe drought and when urged by necessity. The fact, however, is no derogation to the usefulness of the insect, for its utility as a polleniser more than counterbalances all its depredations upon fruit.

### DUNDEE BEE AND HONEY EXHIBITION.

FOLLOWING the example of the Manchester Great Show in 1872, the Dundee authorities held a show of honey in connection with their horticultural exhibition on the 7th, 8th, and 9th inst. The Exhibition was held under the auspices of the East of Scotland Bee-keepers' Society, and it occupied one corner of the large Artillery Hall. In all there were 140 lots shown. For the largest and best harvest of super honey the produce of one hive this season, Mr. William Raitt, Liff, Secretary to the Society, carried off the first prize. The supers were five in number and weighed 103 lbs. of fine clean honey. The observatory hives, within which a swarm of Ligurian bees and their queen were to be seen, were objects of great interest to the many visitors which frequented this part of the Show. A great many specimens of bar-frames were filled with comb honey, and these with run honey in glass jars, and different forms of wax, constituted the exhibition. Subjoined is the prize list:—

Largest and Best Harvest of Super Honey, the produce of one hive.—1, W. Raitt, Liff, 103½ lbs.; 2, Robert Cowan, Brechin, 74½ lbs.; 3, John Lorrimer, Broughty Ferry, 59 lbs.  
 Heaviest and Best Single Super, the produce of one Hive.—1, R. Steele, Fowls, 49½ lbs.; 2, Mrs. Dick, Kerriemuir, 41 lbs.; 3, D. Robertson, Fettercairn.  
 Best Super in Wood, or Wood and Glass.—1, James Glen, Arbroath; 2, W. Raitt, Liff; 3, J. Strachan, Farnell.

Best Sectional Super over 2½ lbs., Combs separable, and not exceeding 4 lbs. each.—1. W. Raitt, Liff; 2. D. Ramsay, Biddovie; 3. J. Stewart, Arbroath.

Best Super in Glass.—1. W. Raitt, Liff; 2. A. Watson, Milnathort; 3. G. Paton, American Muir.

Best Super in Straw.—1. A. Watson; 2. T. Waters, Milnathort; 3. J. Alexander, Morgan Hospital.

Best Two Combs in Bar Frames.—1. A. Watson; 2. J. Davie, Waukmills, Arbroath.

Heaviest and Best Skep; must be free from brood, and obtained without destroying the Bees.—1. J. Christie, Waukmills, Arbroath; 2. R. M'Gregor, Inchmarlo.

Six lbs. of Run Honey in Show Glass.—1. Mrs. Stuart, Letham Mill, Arbroath; 2. T. Waters; 3. R. M'Gregor.

Two lbs. Wax.—1. W. Raitt, Liff; 2. J. White, Falkland; 3. J. Cannison. Messrs. Scrymgeour's Prize.—1. J. Stewart.

Bar-frame Hive complete, with Floor-board, Super, and Roof, price not over 20s.—1. C. N. Abbott, Hanwell, London; 2. R. Steele, Fowls.

Cheapest Bar-frame Hive, suitable for Cottagers, with Floor-board and Roof.—1. R. Steele; 2. C. N. Abbott.

Best and Neatest Observatory or Unicomb Hive, to be exhibited stocked with Bees.—1. J. Lorrimer, West Port, Dundee; 2. W. Urquhart, Rosebay, Broughty Ferry.

The most beautiful Ligerian Bees, to be exhibited with their Queen in Glass Hive.—Equal, J. Lorrimer and W. Raitt.

A Certificate of Merit was awarded by the Judges to E. Bailey, The Pillars, Dundee, for an excellent collection of Honey Exhibits.

The Judges were Mr. C. N. Abbott, Hanwell, London; and Mr. W. Duke, Newbarns, Kerriemuir.

An apianar of Maryland has secured a beautifully marked breed of bees which he names the Albino. The markings are these:—Beautiful yellow bands; from the bands to the end of the bee is quite white, or a bright silver colour; heads dark velvet colour, differing from the Italian.—(*Rural New Yorker.*)

### OUR LETTER BOX.

**HENS CEASING LAYING** (*Subscriber*).—Hens are now giving up laying and are in moult. At that season the comb shrivels and often turns black. The appearance may, however, be caused by something the birds have picked up. You do not state the nature of their run. If they have their liberty with grass, and the different foods; and medicines they find in it, then we cannot advise you; but if they are in confinement you will do well to give them lettuce especially if it has gone to seed, also grass and soil fresh dug and piled in a heap in their run. We should have liked to know their food. If you can get ground oats feed on them, slak'd morning and evening; give whole corn or kitchen and table scraps for the mid-day meal.

**INDIAN RUNNER DUCK** (*F. G. S. R.*).—We do not know the Duck you name; at least, not by the name you give it.

**FOWLS FOR WINTER LAYING** (*Old Subscriber*).—It is not the property of any particular breed to lay in the winter. It may be said, as a rule, that hens never do so lay. Pullets always do if they are of the proper age. Different breeds lay at different ages; thus Cochins and Brahmás lay before Dorkings and Spanish. Cochins and Brahmás are among the earliest layers. We expect them to lay at five months old; we have known them to begin earlier. They lay well, but become broody. Dorkings are good layers; they, however, want rather a larger run than you seem to have. The non-sitters are Spanish, Houdans, Crève-Cœurs, and Hamburgs. These seldom lay till they are six months old. The Spanish and Crève-Cœurs lay the largest eggs. You require eggs during six months, you must therefore have pullets of different ages, as you cannot expect to have birds laying through that period of time. We should be disposed to have Crève-Cœurs. You would want them five and six months old in October, and if they are wanted to lay at that time they should be on their walk at least a month previously. They require at that time of the year to be well fed, and will not lay regularly unless they are. Where it is wished to make the production of eggs a certainty during the winter months attention must be paid to the feeding. When snow is on the ground fowls should be fed from some vessel, as nothing tends to disturb the health of fowls more than to eat snow. For this reason it is well to sweep a place where the trough may stand. They can then pick up the scattered pieces without injury. They must be fed regularly.

**BLACK SPANISH AT WYMOUTH SHOW.**—Mrs. Allsopp writes to say that the cock in her pen of Spanish which were not noticed in the prize list had not his comb cut.

**FOWLS FOR TABLE USE** (*G. H.*).—Taken as table fowls, and compared one with the other, the Houdan would rank before the Brahma. It would, therefore, be better to use the Brahma cock and the Houdan hens. It is not, however, a judicious cross, as the Houdans are non-sitters. Dorking hens would make a much better cross. The last time we saw well-filled "Redcap" classes was many years ago at a show held in Sheffield. They were purely fancy birds, in no wise superior to other and better known breeds.

**SEBRIGHT BANTAMS** (*L. V. A.*).—The Sebright Bantam is a composite bird, and for this reason will sometimes throw back to its forefathers, many of which were single-combed birds. Many good breeders of these run them together and breed both colours. We have done it ourselves; the result has been to make the silver creamy in colour instead of dead white. As it is very necessary to introduce fresh blood continually, we recommend you to make your walk next year of the silver cock, two of the palest of his daughters, and two fresh silver hens. You should take care of the cock, as many of this breed are not stock-getters.

**SUNFLOWER SEED** (*H. J. B.*).—Extract the seed when ripe and scatter it before the fowls.

**DEPRIVING BEES OF THEIR HONEY** (*B. S.*).—You will succeed next time, and need no more information as to driving bees. After well smoking the bees carry the hive further from the stand—as far as you like—and there drive them. If the cloth is properly rolled round the junction of the top and bottom hives not a bee will molest you. Drum constantly for twenty minutes, and you will then find almost all the bees in the top hive. Kill all that remain with powder or sulphur. You will thus safely get the honey and save the bees. One successful effort by yourself will make you quite master of the work of driving. All you seem to lack are courage and confidence.

**WINTERING BEES IN GLASS SHADE** (*T. White*).—It is possible to winter bees in your large glass shade, 18 by 16 inches. The bees in it now have

either been a very late or small swarm, for according to your account they have built one comb only down one side. You should put a wooden ladder from bottom to top in the centre of the shade. Put (units) another to those already at work, and give them 20 lbs. of good sugar syrup, from which they will build several combs for honey and brood. Please to remember that unless the bees hatch several combs of brood in autumn they will die off in winter or in early spring. Your glass shade makes a handsome crystal palace for bees, and the satisfaction of having wintered bees in it will be an ample reward for the special attention now necessary. Keep the palace well covered at all times.

**BEE-KEEPING** (*Phonetic*).—Apply to Neighbour & Co., Regent Street, London, for Payne's improved cottage hive. Your better way will be to purchase a hive of bees, either now or in spring, rather than a swarm. If you buy one now it should have food enough in it to keep the bees all winter. Write to Mr. Jas Hale, Kedington, Haverhill, Suffolk, or to Mr. A. Pettigrew, Sale, Cheshire.

**PRESERVING KIDNEY BEANS** (*F. A.*).—We have known them kept quite fresh until March, and in one or two instances until beans came in again. The process was simply gathering the pods when of a size fit for use, on a dry day, and during dry weather if possible. A thin layer was then placed at the bottom of a stone jar, then a thin layer of fine salt so as to cover them, and on this a layer of beans, then salt, and so on until the jar was full. We cannot say how much salt was used, but we think that it was equal to one-fourth of the bulk of the beans.

**INDIAN CORN COOKING.**—"S. V. B. D." wishes for a recipe.

### REMARKS.

6th.—Very wet night and morning, but a very pleasant day afterwards.

7th.—Fine early, but rain soon after 9 A.M.; showery day; distant thunder between 1 and 3 P.M.; fine night.

8th.—A fine fresh (but for the time of the year) cold day.

9th.—Fair early, but rain before 8 A.M.; a showery day, the rain at times heavy and the sun at times very bright.

10th.—Fine morning; dull forenoon; fine afternoon and evening, and starlit night.

11th.—Fair but showery-looking all day; fine night.

12th.—Rainy morning, but fine soon after 10 A.M., and so continuing all day. A very pleasant day.

Mean temperatures about 2° lower than during the previous week. Rain very frequent.—G. J. SYMONS.

### COVENT GARDEN MARKET.—SEPTEMBER 13.

THE market continues thinly supplied with nearly all classes of goods with the exception of Apples, there being a larger quantity arriving than was anticipated, but prices remain much the same, business being generally very quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 66.0°; and its night temperature 44.3°.

## ROSES IN AN EXPOSED SITUATION.

ROSES in beds or borders are very ornamental; they are also the most esteemed of cut flowers. National indeed is the Rose, for it is everybody's flower, and its enjoyment is not restricted by its costliness of production. Brawny hands, hardened by toil in factory, workshop, mine, or other occupation, prompted by the mind of their possessors who, residing in street or alley without a yard of ground to cultivate, and employ their leisure hours pleasantly and profitably, pluck, when opportunity offers, the Rose of the wilderness—the Dog Rose, proud to possess in the button-hole so primitive a representative of the national emblem, prizing the “blushing bud” as highly as the most enthusiastic rosarian its most improved and noblest flower.

Though we should hail a legislative enactment prohibiting houses in towns without frontal gardens, and houses in rural districts without garden ground adjoining sufficient to produce a supply of vegetable diet, to say nothing of fruit and flowers, fostering as they do home tastes, and affording healthy employment and profitable relaxation, yet we cannot but look upon the apologies for lawns in towns and the providing of large garden plots for those who must labour almost from daylight until dark as other than mistakes; the former is a misappropriation, and the latter converts relaxation into labour. Moderate-sized gardens have a much better chance of being well kept and profitably cultivated than large gardens; and if larger plots are needed to supply the requirements of any, their wants will be better met by allotments.

But what has that to do with Roses in exposed situations? Much; for no exposure is so draughty and trying as that of street gardens. The winds sweep up them, and by being direct in their course form eddies or whirls that batter or twist everything in the way of vegetation. It is hard to tell whether smoke, dust, confined space, or wind are the greatest hindrances to gardening in towns. Walls are all very well as shelter, but unless they are clothed with verdure are very unsightly, and do not “sift” the wind as a “living” wall—a hedge of some kind. Beech may be named as forming a good wind-screen, and it does fairly in towns. Hornbeam, however, does better, and better still Thorn. Those are, of course, deciduous. Ivy will cover a wall or any fence, only train it up, and Clematises appearing upon its surface are simply charming. The best of all shrubs for standing smoke are Rhododendrons, and where the soil is unfavourable to their growth Aucubas may be planted, but they are not nearly so satisfactory as Rhododendrons. In a fairly sheltered town garden Roses may be grown tolerably well, selection being made of the vigorous hardy-constitutioned kinds. It is more easy, certainly, to grow Roses in an exposed situation in the country than in a town garden. I find, however, that in town or country the cultivator must be prepared for “cross currents”—

the wind does not always blow straight—success in most instances being alloyed with failure. I have grown Roses in smoke at a similar altitude for about the same length of time that I have striven to grow them in an exposed situation in the country with results that can only be set down as a mixture of failure and success. I have looked around me, and I find it is much the same in the case of others under similar circumstances.

I was told the other day that my Roses looked as if they wanted “more shelter. Why not give them it—a hedge of Yew or similar wind-screen?” We are seeking to afford the requisite shelter, not to anything in particular, but to everything in general, by planting groups of trees and shrubs, mostly evergreen, and these are disposed in the natural or picturesque style, all the lines being curves and all the figures irregular. To introduce a hedge with either curved or straight outline would be to make a penfold quite out of harmony with the surroundings. Instead, therefore, of forming fields by enclosing an open space with a hedge I have introduced groups of Roses to harmonise with the irregularity of the groups of trees and evergreens. So far as groups of shrubs can afford shelter to associated groups of Roses it is given, but this is of a different character to that afforded by a continuous line or hedge. Our exposure is to the west and north-west; the winds from those quarters sweep over mile after mile of moor, aglow now (early September) with the rosy-purple blooms of Ling (*Calluna vulgaris*); whilst from south-east to north-east the winds reach us after lashing the North Sea into foam as merciless and unrelenting in their attacks as the Norsemen of old, and far more fleet, scaling our height of over 500 feet with an impetuosity that tries severely the resistance of the obstacle opposed to their course.

As might be expected standard Roses are not suited for such a situation; they do not look well, and, what is of more consequence, do not thrive. Standards may do in sheltered situations in soils that suit the Briar, but in a cold exposed situation they are unsatisfactory and expensive to maintain. Rose bushes on tall stems may have originated in the idea of having the flowers produced on a level with the eye, so that the fragrance of the flowers may be inhaled without stooping. A Rose to be seen in all its glory does not want to be on a level with the eye, but beneath it; its fragrance if not worth stooping for is not worth having. Standard Roses in little circles on lawns are inappropriate—a fritting away of the beauty of a lawn and making it appear smaller than it really is. It would contribute immensely to the effect were scattered Rose bushes collected into a bed or border, where they would also be more enjoyable from the advantages of admitting comparison by the varieties being adjudicated upon in juxtaposition, instead of inferential derivations being drawn from isolated subjects.

Notwithstanding the effectiveness of Roses in the mass as compared with solitary specimens they must be of one variety in each mass; for the pinks, roses, crimson, reds, whites, and yellows vary so much in tint and are so dissimilar in habit that when an attempt is made at assorting

them into groups of pink, &c., in variety the result ends in incongruity. These remarks must be taken as not applying to lines of one kind in borders, or beds of one kind in a bed; the effect of these will be equal to that of any other mode, but the varieties in such arrangements must be few and distinct.

Roses must also be tastefully grouped in rooms. It has been said they never look so well as in heaps. I doubt it. A number of insignificant blooms in quantity may hide their defects; but singly every quality of the blooms is presented. In the heap any quantity will pass muster. A few good blooms interspersed make gorgeous an otherwise very indifferent lot; whereas in singles nothing short of good blooms are available. The former plan is the easiest, and if any doubt exist upon this head take a vase that will hold, say, three dozen blooms, and have the same number of small glasses somewhat larger than a penny ink-bottle, each to be filled with a specimen Rose, and you may find, as I have, what an easy matter it is to fill the vase, and what a difficulty there is in finding three dozen specimen blooms every other day of a creditable character.

A word as to garden *versus* exhibition Roses. I find all really good garden Roses are those appearing in the winning stands at shows, with the exception of a few of doubtful hardiness, and some that require walls. A Rose is not fit for a garden unless suited for exhibition. There are as good hardy Roses as those of doubtful constitutions; but some have a mania for everything that is tender, and requires a wall or glass to grow it, not for its merits but on account of the greater difficulty of production. This is also encouraged by judges, who often countenance rarity instead of quality.

The Briar here in the open presents a stunted growth. It is only when sheltered that it draws up long enough to form a stem. These stocks are planted thickly for trade purposes, the stems not being subjected to the drying influences of the atmosphere until given the cultivator's distance. By exposure to sun the stem may dry before the head is of a size to protect it, the stem in its habitat being protected by its own or surrounding growth, and this exposure of stem may account for the many deaths resulting, not so much of the Roses as of the Briars. It is not solely due to the tenderness of the Rose, though that in a severe weather may be a sufficient cause of loss, but the sap for some untold reason refuses to ascend the stock, as is evidenced by want of growth on the stems; and the presence after its death of numerous suckers springing from the roots is proof conclusive that nature, distorted as it may be, will in the long-run assert its supremacy. The only Roses which the Briar appears to suit are the vigorous spreading growers; but neither as dwarfs, quarter, half, or full standards does the Briar answer with me as a stock, standards of any height not being suitable for any exposed situation. I must, however, in justice to the Briar say that a few dozen plants alleged to be on Manetti, but which were on Briar roots, which had been cut into lengths of 3 or 4 inches and worked, and planted so that the junctions were covered at least 3 inches with soil, have done well. They, however, send up suckers, it being the nature of the Briar to put out strong young growths from the roots annually.

The plants for an exposed position are dwarfs. Upon their own roots only a few of the most vigorous succeed, and these do not give blooms equalling those afforded by the Manetti, which are planted so that the junction is 3 inches beneath the surface, it being remarkable what a few plants root from that part of the scion which is buried, and what few suckers are produced. The ground for them was trenched two spits deep; the subsoil being unfavourable and full of oxide of iron, it was not thought desirable to bring more up. The soil is of a semi-peaty description, admirably suited to American plants, and naturally grows Heather in three species—Whins where dry, and a few Bilberries, and, where wet, Sedges. Poor stuff! In trenching the turf went to the bottom, and upon this was given a coating of farmyard manure 6 inches thick in its fresh state, and then the bottom spit was brought to the top, a like dressing of manure being placed on the top and mixed with the top spit. Spring had come in before planting could be done, and I cut hard back at the close of April, the Roses having begun to grow. I like to have the shoots start from near the ground, below it when possible. They grew away finely, but the hares soon found out the daintiness of the tender shoots, and ate them off to very near their origin. Wire netting had to be brought into requisition, the plants having scarcely a leaf on them at Whitsuntide. It was clear the hares had only caused more shoots to come in place of

those removed, and we had lots of Roses in late summer and autumn.

In December the soil was mulched, or rather covered up with litter. I had anticipated the appearance of the litter would have prompted an order to take it away, and the Roses also if they would not do without it; but whether the perfume of the Roses had been so enduring as to prevent any odour arising from the litter, or their colour still filling the eye so as to hide the unsightliness of the straw I am not in a position to state, but the order did not come, and I have gone to the extent of summer mulching, which has not been taken objection to. Had I had my own way I certainly should have gone to the extent of a rosery—hid the noblest of flowers behind a hedge; but the fact was, they as shrubs must take their position as such or not at all. It is only just to say that they attract much attention and elicit great admiration. I mention this as an encouragement to others similarly circumstanced—not to let a difficulty, often imaginary, stand in the way, for though the result may not equal others more favourably circumstanced, every effort is attended with more or less of success, generally measured by the enthusiasm of the cultivator for the subject which he labours to perfect.

The roughest of the winter covering is removed in early spring, and comes in admirably for mixing with fresher hotbed material, and the shoot is pointed-in after pruning, which has often been done too early, as when done in February and early in March the shoots have not unfrequently been much damaged by frost in April, and I do not now prune until the early part of that month if the season be forward, and not until the middle or end if the season be late, the growths upon the shoots being often considerable before pruning is done. By late pruning damage is escaped from spring frosts, and the bloom though later is certainly finer. The plants are gone over occasionally through the summer, removing any past flower trusses, and cutting-back any long non-flowering shoots to the height of the plants generally, and these not unfrequently afford shoots giving bloom without interfering with the buds at the base of the shoots. In the matter of pruning, the weak and old shoots are cut clean away, the endeavour being to originate strong vigorous shoots. The pruning is also close—each strong shoot being cut to three or four eyes, and the moderately vigorous to two or three.

All that the plants are allowed beyond the covering-up in winter is in a dry summer a mulching of short litter after the first moist weather in June, weeds being kept under, and if no mulching be given—which is not always the case, the weather being moist and the growth free—the surface is kept from cracking by stirring the surface. No watering is given overhead or to the roots. There is no aphid and no mildew. We commenced with many kinds, but each year has considerably reduced their number; their place has been taken by such as succeeded, and which were free in growth and flower, and have proved suitable for an exposed situation. I have placed those following in the order of merit.

*Hybrid Perpetual*.—John Hopper, Baroness de Rothschild, Alfred Colomb, Charles Lefebvre, Sénateur Vaisse, Capitaine Christy, Edward Morren, Madame Victor Verdier, Dupuy-Jamain, Thyra Hammerick, Countess of Oxford, La France, Madame Clert, Paul Neron, Prince Paul Demidoff, Duke of Edinburgh, Antoine Ducher, Madame Lacharme, Thomas Methven, Comtesse de Chabillant, Prince Camille de Rohan, Maréchal Vaillant, Claude Levet, Pierre Seletzki, and Olga Mariz, small but a finely-formed flower.

*Perpetual Moss*.—Madame Moreau and Salet.

*Bourbon*.—Louis Margottin, Sir Joseph Paxton, and Baron Gonella.

*China*.—Cramoisie Supérieure and Mrs. Bosanquet.

*Tea-scented*.—Gloire de Dijon—this and the first twelve are much the best; Gloire de Bordeaux.

*Noisette*.—Rêve d'Or, magnificent foliage, but blooms sparingly, but well worth a place where leaves are in request.

There are, of course, many others that are vigorous growers, but the flowers do not open, notably Perle des Blanchés and Princess Christian, Perfection de Lyon being most refractory in that respect.—G. ABBEY.

## PEACHES IN ORCHARD HOUSES.

THESE are now so plentiful that anything relating to them interests many. On p. 245, in reply to "READER," some observations are made on the comparative flavour of fruit under glass and on the open wall. I believe it depends on the season, but

in no season have I ever tasted a Noblesse Peach grown under glass equal to one ripened in a fine season on the open wall. Peaches in pots require, no doubt, constant attention as to water, and any error here may deteriorate the fruit; but I believe the real cause of inferiority is the difficulty with which the actinic (not the luminous) rays of light pass through glass. The fact of such inferiority was noticed by Andrew Knight, and he constructed a Peach house expressly to allow two sets of trees to receive in their turn the direct rays of the sun without the intervention of glass. In his case the trees were planted out.

In the answer above referred to manure water is not recommended. I find rotten hay a good covering for the surface, and the roots seem to like it much. This is refreshed with weak liquid manure, which is discontinued as soon as the fruit is fully swollen. If used with moderation it seems useful.

Why are bones prohibited? If fresh they are of course objectionable, but when decayed and in a porous condition roots penetrate them readily. They seem beneficial both mechanically and chemically.—G. S.

### BEDDING-OUT PLANTS.

I AM almost entirely in accord with the article on bedding-out plants which was extracted from "The Gardener," and appeared on page 217 of the *Journal of Horticulture*. There is no reason why, when there is room and a proper situation, that persons should not grow more herbaceous and perennial plants; but each year more and more convinces me of the difficulty of keeping beds of perennials tidy and gay for any length of time, and that it would not do to have mixed perennial borders, instead of bedded-out plants, in any formal garden close to a house where it is to be daily seen from the windows. There is no reason why choice half-hardy plants should be anyway inferior to choice perennials, and there can be no doubt that those plants which have been generally selected for bedding purposes are more lasting and give more continuance of bloom than almost any other kind of plants. If persons are content to see constantly under their windows or on their parterres (a word which, by the way, I hate—why not say gardens or lawns?) a geometrical bedded-out garden cut out of coloured foliage, presenting day by day the same features, except when it may have been newly cut or clipped, then of course there is no necessity for flowering plants, and both perennials and half-hardy flowering plants may go to the wall. I have no fear, however, that lovers of flowers will long be content with the sort of thing I saw in front of a ducal mansion in the south of England—a dead flat without a flower, and a badly laid-out carpet of Sedums, Alternantheras, *et id genus omne*. English people are essentially lovers of flowers, and while foliage may help to diversify and adorn, foliaged plants will not for long be allowed to cover the whole of a bedded garden.

Neither, again, do I see the wisdom of growing every kind of perennial, be it high or be it low, be it alpine or be it herbaceous, merely because it is a perennial and hardy. No doubt many of our most beautiful plants, as Phloxes and Delphiniums, Sweet Williams, &c., are perennials; no flowers, perhaps, when massed produced finer effects in the distance than Phloxes and Foxgloves and Antirrhinums; but then, with some few exceptions, their season is but short, and something must be put to supply their place, or else there is a blank. If we try to make a perennial border with low-growing flowers in front it will be found that nearly, if not all, are spring plants, as Arabis, Aubrietia, Myosotis, Auriculas, Polyanthus, Anemone, Pansies, &c., and if the front of the border is gay with them in May and June, what is to supply their places in July and August, unless annuals are pricked-in amongst them to the detriment of the other plants another year? Again, if the back row is gay with Sweet Williams and Snapdragon in July, what is to supply their place in August should the summer be dry? Phloxes seem to me among the most valuable of perennials, to say nothing of Gladioli, Liliums, &c., but under no circumstances does it appear to me that a mixed perennial border can supply the place of a bedded-out garden, where flowers as flowers strictly predominate. If proper care is taken in the selection of sorts and arrangement of colours there need be no undue glare or formality.

The mistake too often made is to substitute quantity for quality, or to repeat over and over again the same Geranium, or same Calceolaria or Lobelia, simply because it seems to thrive or propagate easily. I have, for instance, on a sloping bank in my garden twenty beds of Geraniums, ten of which

are pinks and ten scarlets. Many persons would have repeated the same pink—say, perhaps, Christine, and the same scarlet, perhaps Vesuvius, for the whole of the twenty beds. I have carefully avoided having two alike. I have selected ten pinks, five of them with a lilac tinge, and five of a true pink in different shades, and ten scarlets, five of which are crimson in tone and five vermilion; but there are sufficient diversities in the tones and habit of growth, size of truss, colour of foliage, &c., to help to prevent monotony and to add to the interest, not merely by comparing the different varieties, but also by blending the shades of colour. Again, I find by experience that large trusses are far more effective than small, even though there may be three times the number of smaller trusses, and that those that throw-up a quantity of small trusses as Vesuvius, never last. Others, again, like Jean Sisley, will not stand sun or drought.

I have the following beds in the bank this year:—Mrs. Fytche, John Gibbons, Florence Durand, Rev. J. F. Atkinson, Mrs. Holden, Bayard, Amaranth, Star of Fire, Mrs. Augusta Miles, Le Grand, Mrs. Lowe, Mrs. Whiteley, Mrs. Musters, Sir J. Outram, Contessa Quarto, Vesta, Amaranth No. 2, Corsair, Rose Rendatler, and Mrs. Vincent. This is the order in which they are planted. Amongst these John Gibbons, Rev. J. F. Atkinson, and Mrs. Whiteley are new varieties of Mr. Pearson's; the first two of strong growth with enormous trusses and large individual flowers, one a true scarlet the other a crimson, and both very effective. Mrs. Whiteley is rather like Jean Sisley but a better flower, and does not drop its petals in the sun. Most of the others will be known to many of your readers. Among the scarlets Star of Fire and Corsair still keep-up their character; and among the crimsons Bayard and Sir James Outram. There is no light pink which has yet with me surpassed Mrs. Lowe; and among deep pinks Mrs. Fytche, Mrs. Holden, and Augusta Miles are particularly fine. Florence Durand always does well towards the latter end of the season, but Amaranth is invariably good among the lilac shades, and equally good is Mrs. Musters. Another lilac which I have bedded this year for the first time is Mrs. J. F. Fenn, and this year it surpasses both Amaranth and Mrs. Musters, and is one of the largest-trussed Geraniums I ever saw, and at the same time a free bloomer with a good stiff flower stalk. The same trusses have continued in bloom for more than ten weeks, so that trusses which were on the plants when bedded-out in the end of May were still giving flowers in August.

In a large oval bed round which I have trial sorts of Geraniums, I have twelve newer kinds this year. Lucy Bosworth, a pink, is beautiful in pots, but does not promise to bed so well as some others. The same may be said of Lady Byron. Mrs. Huish, one of the old Lord Palmerston type of colour with larger trusses and brighter flowers, has been very promising. In another bed Frank Miles with enormous trusses has had a very massive appearance. Lady Stanhope and Sir H. Stanhope have also done well. The first is an admirable pot plant. Among older sorts, Arthur Pearson, Rose Bradwardine, and Lady Kirkland have still held their own; and last, but not least, except in stature, Violet Hill Nosegay has been as good as ever with me in a row under the windows of my house, where almost every other Geranium would have gone to seed or else grown too grossly.

Among tricolors William Sandy has been the best, and Macbeth next to it. Lady Callum, Edith Pearson, Sophia Dumaresque, and Sophia Cusack have all done well. I will pursue my remarks in another number.—C. P. P.

### POT VINES IN THE OPEN AIR.

It is a very common practice to remove Vines growing in pots from a close warm house into the open air in autumn. Places in which Vines are growing throughout the summer are often wanted for other plants when the cold days and nights set in, and the idea seems somewhat general that any kind of treatment will suit young Vines after the wood is fully developed. This is a great mistake. The future success of a young Vine does not depend so much on its great thickness as being thoroughly well ripened, and placing the Vines in the open air is certainly not the surest way of securing this. They may not be "tucked up against an open wall" until the wood is brown to near the point; but it is very well known that Vines assume a brown hue long before the wood is hard and ripe, and while the leaves are quite green. Vines of this description must be checked severely when taken from a close atmosphere and exposed to all weathers in the open air.

I have seen young Vines placed outside in September when the wood was a dappled green and brown colour, and the leaves quite fresh and green; but these were soon tattered and discoloured with the wind, and when the canes came to be planted they were no riper than when they were first placed outside. The very best of treatment will not ensure success with Vines like these, in fact I believe many failures with young Vines might be traced to this very cause.

\* No young Vine should ever be placed outside in autumn as long as there is an inch of unripened wood about it, and every leaf has fallen through maturity. They will then withstand a great amount of cold and exposure without injury so long as the roots are protected from excessive wet. There is another operation often practised on young Vines, which I question very much the advantage of, and that is pulling the principal leaves off with the hand before the foliage shows any signs of dropping. This must severely check the development of the buds, and cause the wood to shrivel and go to rest prematurely.—VITIS.

### THE AUTUMN PRUNING OF FRUIT TREES.

A NEIGHBOUR who has read my notes on this subject in your last issue of the Journal (page 230) reminds me that I have made what in his opinion is an important omission. The point which is left unnoticed is the second growth, which he considers would result should a long mild autumn succeed the pruning in September which I advocated. As it has occurred to me that others may be of the same opinion as my neighbour, and may consequently hesitate to thin-out their overcrowded trees until they are divested of their foliage, I will not wait for public interrogation, but will anticipate inquiries by further recording my experience on the after-growth resulting from pruning, not in autumn only but also in summer and winter.

My friend is quite right that if a long moist autumn succeeds the September pruning a second growth might issue from the terminal buds, although in practice I have not found it to be so. It is as well to remember that the pruning which is especially beneficial in September is the total thinning-out of superfluous branches and shoots rather than the extensive shortening of growing parts. When the leaves are on the trees the requisite amount of thinning has not to be done by guess-work, but the operator can tell exactly which branches to remove, so that the foliage of those remaining may have light and air.

Now in the case of the branches thus removed they are generally cut where the wood is two or more years old and which contains few if any prominent buds, and the arrested sap is generally appropriated by the foliage remaining on the other branches; and the latent buds near the points from which the branches have been severed remain in a dormant state, at any rate until the succeeding spring, when they will frequently push into growth. Occasionally they commence growing in the autumn, and, if they do, all that is required is to rub them, not cut them off. This second growth is, however, precisely what follows after winter pruning. Fresh growth issues on the moving of the sap in spring, and is soon hidden in a great measure by the surrounding foliage then quickly expanding, and thus has pruning not unfrequently resulted in making the trees thicker than before. Unless fruit trees are looked over in the spring and summer following their winter's pruning, and the young clusters of shoots are rubbed off the snags and branches where such growth is not required, the results of the pruning are in a few years rendered nugatory if not indeed in some cases pernicious.

In respect also to early summer pruning, the second growth issuing is too often left untouched until the winter pruning; and probably at the present moment—in fact I am sure that it is so—there are many trees which cannot sufficiently mature the fruit-bearing wood in consequence of the shade and active sap-movement caused by a mass of sappy "second growth." This second growth should be removed at once in order that the leaves at the base of the shoots and surrounding the spurs can have the light which is so necessary in rendering the trees fruitful.

I have never hesitated towards the end of the summer to remove what I considered superfluous shoots and branches from Peach and Nectarine trees both on walls and in houses, and I have freely and beneficially adopted the practice with trees of Apples, Pears, Plums, and Cherries, which are growing as pyramids and standards. I have always found the wounds heal better when made at that time than at any other, and it is

certain that the trees have been greatly benefited by the full exposure of their foliage to light and air.

Let pruning be done whenever it may—in summer, winter, or autumn, it is very necessary that the trees be examined a few months afterwards in order that the succeeding growths which issue from near the parts which have been cut be rubbed off where not required, or thinned-out and pinched where it is desirable to form spurs and retain foliage. Pruning is only half done when the knife is put in one's pocket—that is, the benefits which are expected from it are only half provided for, and to complete the work careful attention must be given, and given in time, in removing or assisting the growths succeeding. I have thus endeavoured to supply the omissions pointed out to me by my critical neighbour, and anyone having a knowledge of trees will see that the matter now alluded to is important and worthy of attention.

An intelligent use of the knife at the present time in removing superfluous branches cannot fail to be beneficial to the trees, following the practice by subsequently rubbing-off or pinching the after-growth, or the trees will in a very short time become thicker than before and less fruitful in character.—A NORTHERN GARDENER.

### OUR NATIONAL EMBLEMATIC PLANTS.

SOME notes on these were in this Journal a few weeks since, and I hoped to see others, but as they have not appeared I copy the following from a MS. volume. Many centuries before the wars which

"Sent, between the red Rose and the white,  
A thousand souls to death and deadly night,"

the flower had been famous in our island, and its emblem was and is the *Rosa anglica alba*, the white English Rose. Some writers have thought that the name Albion was applied to our island on account of the white Roses it produced.

The Thistle is the emblem plant of Scotland, and if the tradition was founded on fact it is the Stemless Thistle, *Cnicus acaulis*. According to that tradition the Norsemen would have surprised the Scotch clans in a night attack if one of their spies had not uttered a loud imprecation upon treading barefooted upon one of these Thistles. The clans dubbed the plant "The Scotch Thistle," and it was accepted as a representative plant, and the appropriate complimentary motto attached, *Nemo me impune lacesset*—No one injures me with impunity.

It is doubtful what plant was first adopted for Ireland's national plant. Shamrock is a corruption of the Irish "Seamrog," which is applied to many plants, as the Wood Sorrel, purple Clover, Speedwell, and Pimpernel.

The Irish are said to have adopted the Shamrock as a badge when converted to Christianity in the year 433 by St. Patrick. They adopted it because he used the three-leafed plant as an illustration of the Trinity.

St. Patrick probably held up *Oxalis acetosella*. Clover was not introduced into Ireland until centuries after him, and the plant he held up was eaten by the Irish, which points to the *Oxalis*.

Why or when the Welsh adopted the Leek as their national emblem is not known. None of their early bards mention it.

The Tudor colours were green and white, and these were well represented by the Welshmen of Henry VII.'s body guard wearing a Leek in their caps at the battle of Bosworth. There is in Wales a tradition that the Saxons attacked the Britons on St. David's-day and put Leeks in their caps as a distinguishing badge, but the Britons proving victorious transferred the Leeks into their own caps from the caps of those they had slain or taken prisoners. Among the Harleian MSS. is a poem referring to this event, and adding—

"Next to the lion and the unicorn  
The Leek's the fairest emblem that is worn."

Some authorities state that the Leek has become the national plant of Wales because its farmers from time immemorial, when they aid each other in ploughing, according to a custom termed *Cymbortha*, bring nothing but Leeks for their sustenance, all other requirements being supplied by the farmer they are helping.—G.

### MUSA ENSETE.

To grow this monstrous-leaved plant to perfection it must be planted out. I saw a couple of it the other day at the Duke of St. Alban's place, Bestwood Park, Nottingham. Twelve

months ago they were small plants in pots about 3 feet high. They were then planted out in a bed in the large conservatory, and the leaves now extend to a height of about 24 feet. They are two of the finest specimens in the conservatory. The substance they are growing in is nothing but pure loam, and Mr. Edmonds, the gardener, attributes their rapid growth to the great quantities of water with which they have been supplied throughout the summer.—VISITOR.

#### ASSOCIATION OF PLANTS, BIRDS, AND INSECTS.

At the recent meeting of the British Association Mr. A. R. Wallace delivered a lecture, from which the following is extracted:—

Ever since Mr. Darwin showed the immense importance of insects in the fertilisation of flowers great attention has been paid to the subject, and the relation of these two very different classes of natural objects has been found to be more universal and more complex than could have been anticipated. Whole genera and families of plants have been so modified as first to attract and then to be fertilised by certain groups of insects, and this special adaptation seems in many cases to have determined the more or less wide range of the plants in question. It is also known that some species of plants can be fertilised only by particular species of insects, and the absence of these from any particular locality would necessarily prevent the continued existence of the plant in that area. Here, I believe, will be found the clue to much of the peculiarity of the floras of oceanic islands, since the methods by which these have been stocked with plants and insects will be often quite different. Many seeds are, no doubt, carried by oceanic currents, others probably by aquatic birds. Mr. H. N. Moseley informs me that the albatrosses, gulls, puffins, tropic birds, and many others nest inland, often amidst dense vegetation, and he believes they often carry seeds attached to their feathers from island to island for great distances. In the tropics they often nest on the mountains far inland, and may thus aid in the distribution even of mountain plants. Insects, on the other hand, are mostly conveyed by aerial currents, especially by violent gales; and it may thus often happen that totally unrelated plants and insects may be brought together, in which case the former must often perish for want of suitable insects to fertilise them. This will, I think, account for the strangely fragmentary nature of these insular floras, and the great differences that often exist between those which are situated in the same ocean, as well as for the preponderance of certain orders and genera.

The unusual proportion of Ferns is a general feature of insular as compared with continental floras; but it has, I believe, been generally attributed to favourable conditions, especially to equable climate and perennial moisture. In this respect, however, Tahiti can hardly differ greatly from many other islands which yet have no such vast preponderance of Ferns. This is a question which cannot be decided by mere lists of species, since it is probable that in Tahiti they are less numerous than in some other islands where they form a far less conspicuous feature in the vegetation. The island most comparable with Tahiti in that respect is Juan Fernandez.

Now, as far as we know, the extreme entomological poverty of Juan Fernandez agrees closely with that of Tahiti; and there are probably no other portions of the globe equally favoured in soil and climate and with an equally luxuriant vegetation where insect life is so scantily developed. It is curious, therefore, to find that these two islands also agree in the wonderful predominance of Ferns over the flowering plants—in individuals even more than in species, and there is no difficulty in connecting the two facts. The excessive minuteness and great abundance of Fern spores causes them to be far more easily distributed by winds than the seeds of flowering plants, and they are thus always ready to occupy any vacant places in suitable localities, and to compete with the less vigorous flowering plants. But where insects are so scarce all plants which require insect fertilisation, whether constantly to enable them to produce seed at all, or occasionally to keep up their constitutional vigour by crossing, must be at a great disadvantage; and thus the scanty flora which oceanic islands must always possess, peopled as they usually are by waifs and strays from other lands, is rendered still more scanty by the weeding-out of all such as depend largely on insect fertilisation for their full development. It seems probable, therefore, that the preponderance of Ferns in islands (considered in mass of individuals rather in number of species) is

largely due to the absence of competing phænogamous plants; that this is in great part due to the scarcity of insects. In other oceanic islands, such as New Zealand and the Galapagos, where Ferns, although tolerably abundant, form no such predominant feature in the vegetation, but where the scarcity of flower-haunting insects is almost equally marked, we find a great preponderance of small, green, or otherwise inconspicuous flowers, indicating that only such plants have been enabled to flourish there as are independent of insect fertilisation. In the Galapagos—which are perhaps even more deficient in flying insects than Juan Fernandez—this is so striking a feature that Mr. Darwin speaks of the vegetation as consisting in great part of “wretched-looking weeds,” and states that “it was some time before he discovered that almost every plant was in flower at the time of his visit.” He also says he “did not see one beautiful flower” in the islands. It appears, however, that Compositæ, Leguminosæ, Rubiacæ, and Solanacæ form a large proportion of the flowering plants, and as these are orders which usually require insect fertilisation, we must suppose either that they have become modified so as to be self-fertilised, or that they are fertilised by the visits of the minute Dipteræ and Hymenopteræ, which are the only insects recorded from these islands.

In Juan Fernandez, on the other hand, there is no such total deficiency of showy flowers. I am informed by Mr. Moseley that a variety of the Magnoliaceæ *Winter's Bark* abounds, and has showy white flowers, and that a Bignoniaceæ shrub with abundance of dark blue flowers was also plentiful; while a white-flowered Liliaceæ plant formed large patches on the hillsides. Besides these there were two species of woody Compositæ with conspicuous heads of yellow blossoms, and a species of white-flowered Myrtle also abundant; so that, on the whole, flowers formed a rather conspicuous feature in the aspect of the vegetation of Juan Fernandez. But this fact—which at first sight seems entirely at variance with the view we are upholding of the important relation between its distribution of insects and plants—is well explained by the existence of two species of humming birds in Juan Fernandez, which in their visits to these large and showy flowers fertilise them as effectually as bees, moths, or butterflies.

This leads to the observation that many other groups of birds also, no doubt, aid in the fertilisation of flowers. I have often observed the beaks and faces of the brush-tongued lorises of the Moluccas covered with pollen; and Mr. Moseley noted the same fact in a species of *Artamus*, or swallow-shrike, shot at Cape York, showing that this genus also frequents flowers and aids in their fertilisation. It must also be remembered, as Mr. Moseley has suggested to me, that a flower which had acquired a brilliant colour to attract insects might, on transference to another country and becoming so modified as to be capable of self fertilisation, retain the coloured petals for an indefinite period. Such is probably the explanation of the *Pelargonium* of Kerguelen's Land, which forms masses of bright colour near the shore during the flowering season; while most of the other plants of the island have colourless flowers in accordance with the almost total absence of winged insects. The researches of Dr. Herman Müller have shown us by what minute modifications of structure or of function many flowers are adapted for partial insect and self fertilisation in varying degrees, so that we have no difficulty in understanding how, as the insects diminish and finally disappear, self fertilisation may have become the rule, while the large and showy corollas remain to tell us plainly of a once different state of things.

As the sweet odours of flowers are known to act in combination with their colours as an attraction to insects, it might be anticipated that where colour was deficient scent would be so also. On applying to my friend Dr. Hooker for information as to New Zealand plants, he informed me that this was certainly the case, and that the New Zealand flora is, speaking generally, as strikingly deficient in sweet odours as in conspicuous colours. Whether this peculiarity occurs in other islands I have not been able to obtain information, but we may certainly expect it to be so in such a marked instance as that of the Galapagos flora.

#### PETROLEUM VERSUS AMERICAN BLIGHT.

THANKS for the information derived from a perusal of your Journal, I have been able to almost entirely get rid of that pest to my Apple trees, American blight. Last year the trees were completely covered, but after the fall of the leaf I had

them carefully dressed with petroleum, which was applied to the affected parts with a paint brush. Contact with the petroleum seemed to destroy the insects, and I was in hopes they had entirely disappeared. This summer, however, there have been signs of them again, but whenever the blight makes its appearance an application of the brush dipped in petroleum at once extinguishes it. The contact of the oil with the leaves and fruit buds apparently does no injury, and I see that with a little patience and perseverance my trees, which were in a fair way for being ruined, can be preserved.—E. B.

### WOODEN FENCES FOR FRUIT TREES.

THE construction of fences for enclosing small gardens has not hitherto received that attention which it merits. The primary object is of course to define the boundaries of the garden, to exclude intruders, and in towns to obtain as much privacy as may be. The more important points of shelter and warmth, bearing as they do more upon the future than the

posts and rails, and nailing some boards upon them—precisely what is done in many instances. But it should not be forgotten that when trees are found to require the protection of some such weather-screen as this its shelter should be as perfect as possible—there must be no cracks or openings to give admission to the cold blasts of spring; and yet I have seen fences with Peaches and Nectarines trained upon them that had a clear space of half an inch or more from top to bottom between every two boards, which had evidently shrunk after they were nailed upon the rails. It may be that in some instances unseasoned timber has been used and there has been a proportionate shrinkage, for all boards when thus fully exposed are quite certain to contract with heat and expand with cold in some degree; so that the use of the very best seasoned crown memel battens will only afford a modification of the evil if the same faulty method of construction is followed.

The plan which I have found to answer best is not to plough a groove along the edges of the boards and tongue them together with thin strips of deal, but to make a lap or shoulder along

Fig. 32

immediate present, are apparently not much thought of, most fences being deficient in this respect. "W. W.," however, is evidently fully alive to the value of fence surfaces for the culture of delicate fruits as well as for the shelter which a good fence affords; for in his letter of inquiry about their construction he not inaptly terms them wooden walls. I have seen many of them, but never one that was not faulty in some respect or other. It is therefore my purpose in replying to our correspondent to explain fully the details of a really good fruit-tree fence both as to its materials and construction.

The most important points to secure are utility blended with durability, and lightness so far as is compatible with strength—really a plain boarded surface without a single open joint or fissure, fastened securely upon a strong frame of timber. This to the superficial observer would appear a very simple matter—just the putting-up of a certain number of ordinary

the edges, letting the boards overlap each other, and driving the nails through both laps as shown at A, fig. 34, thus effectually preventing any openings at the joints. Fig. 32 represents a very strong boarded fence for fruit trees, designed to meet the requirements of "W. W." and others requiring a high fence or screen. The upright posts should be of oak and 6 inches square in the sawn part A, the rough part B being left as large as possible. This part, being buried in the earth, will soon decay if it is not previously dressed with some preservative. Steeping in tar is an excellent plan, but as that may prove a somewhat troublesome and nasty operation to many, I may append the valuable receipt of a paint for this purpose which Dr. Hogg gives us in his useful "Year-Book":—"Take boiled linseed oil, and stir-in pulverised charcoal to the consistency of paint. Put a coat of this over the timber, and the exclusion of damp will be perfect. Basswood posts have been

taken up after having been set seven years that were as sound when taken up as when first put into the ground. Time and weather seemed to have no effect on them. The posts should be well seasoned before the oil and charcoal are applied, and the paint should be thoroughly dry before they are put in the ground." The braces c, and the whole of the other timber-spars, coping, and other boards, should all be of the best seasoned crown memel deal; the braces being 4 inches square, the spars 2 inches by 1 inch, and the boards 8 inches wide by 1 inch thick, the laps or shoulders along the edges being half an inch in depth, so that each board would do 7 inches of the fencing. The nails should be  $2\frac{1}{2}$  inches long of the sort technically called fine-clasp, which may be made to turn at the tip and clinch upon the board, and not cut-clasp, which are so brittle that the ends break off if one attempts to clinch them. The boards in every fence, however small it may be, should

Fig. 33.

be fixed vertically as in fig. 32, and not horizontally, in order that no moisture may accumulate in the joints. The single course of brickwork, e, is also strongly recommended for all fences to preserve the bottoms of the boards and to exclude vermin. The coping, 15 inches wide, should be made to go over the plate on the top of the fence, and be supported upon iron brackets screwed upon the fence for that purpose; and there should be an iron bolt or rivet (see A, fig. 33), passing through the end of each bracket and the coping near its front edge to prevent warping, which will otherwise always occur when the sun is powerful.

Fig. 34.

There are many opinions as to the colour which such fences should be painted, many insisting that a black surface is preferable to all others, from the great power which all substances of that colour have of absorbing and radiating the rays of the sun. It should not be forgotten, however, that when walls and fences become clothed with the foliage of the trees trained upon them, so little of the surface is left exposed to the direct action of the sun that the colour becomes quite immaterial. One may therefore very safely conclude to consult one's own taste as to colour, laying most stress upon the painting being thoroughly well done, in order that it may serve its legitimate purpose of a preservative of the body which it covers.

It must not be forgotten that so high a fence as the one figured runs great risk of being blown down if exposed to high winds. There are two ways of making it firm: one by putting stays behind it aboveground; and the other and more generally preferable plan is to put in rough spurs below ground, strutting to the front and back of the fence posts. If these

spurs are large, long, and well rammed about with stiff clay, the fence will brave the roughest wind and the objectionable stays are avoided.—EDWARD LUCKHURST.

### APPLES.

"WILTSHIRE RECTOR" mentions the Hawthornden as bearing good crops this year where all others are failures. I have noticed the same thing in previous years; in fact, it is a kind that rarely fails totally. I always depend on Hawthorndens as early Apples for market purposes, gathering the best fruit first in preference to Keswick Codlin, as the latter are inferior in size. In consequence of this early gathering many of them would come from the tree with the wood attached. I have an idea that by annual spur-thinning I have gained a more regular succession of fruit. Be that as it may, I believe the Hawthornden to be one of the most useful Apples grown, and were I planting an orchard I should use this kind largely. The Keswick Codlin I do not like, it shrinks so much in cooking, and is not nearly so saleable as many others.

I can recommend Domino as a good Apple and very precocious in bearing. I have not heard any other name for it. It can be obtained at any nurseries in the midland counties. But the handsomest crop I ever saw on a young tree was Pike's Pearmain, a splendid Apple. Another good sort for kitchen use, a very free bearer and large size, is the Greasy Coat. I never knew it by any other name, but I do not know any autumn Apple to surpass it.

I seldom see the Scarlet Nonpareil mentioned as a table Apple, to my taste it is perfection.—J. J., Lancashire.

### ELECTION OF ROSES.

AND dost thou think that I be such a gaby that I will tell ye all what Roses I tak to be best? Not I. I be no such a fule as that comes to. I dinna moind naming a two or three which I consider reglar stunners, but unless I be paid weel for it no more will I impart. I doant moind ever telling anything oi knaws for a consideration, but withoot sich a stipulation oi no tells moy moind. Nay, nay, lads; fair play's a jowell, and nowt for nowt, is my twae mottoes.

In this part of t' countrie mony of your fair-weather sailors, your delicate sensitive articles, just turn up their eens and dee as soon as a wee flake of snaw or a sleet comes, or a pinch of frost tak hold on em. But best of all by a long chalk is that reglar stunner the Jeneral. Eh, lads, but he's a moighti fine chap; his colour is loike our Betsy's after she has had twae or three good turns at kiss i' the ring. Some call him Jacqueminot and some Jack, but oi knaws him best by t' name of Jeneral. They tells me that he's been a rare profligate parent, the sire of mony a grand Rose, too numerous to enumerate onless for a consideration. Foremost and grundeest amongst his sons is the Dook of Edingburgh, and I hears that no end of marquises and dooks and lords are descended fra him. He, maybe, is a troife thin and fluffly at toimes, but that is when he has not been pruned enuff; for "spare t' rod and spoil t' chield" is moighty true about the Jeneral. After him cums yon famous variety, that like England's flag has stnd the battle and the breese for twenty years or more, auld John Hupper. I was right capped when furst I saw a posy made up of that Rose. Nae thinness or weakness of constitution about auld John. Ivery pital croudged on to its nabor; of a foine deep rose colour, someat loike our untsman's coit when its a leetle the war for wear, but not near so many spots in it. Folk say that this ere Rose is loike the coit, and is not what it ance was, which they say is deterioriated, or sum sich grund word, but wi' me here in t' north it niver fails to plaize.

Next in moi esteemation cums Gloiry of my John. They calls him a Tea Rose I beleeve, but whoy or wherefore I canna tell, for he's as strang and as erect as Gog and Magog or any ither friend of theirs. Put him where ye wull, and he'll cloimb and grow till he's that gross that you have to cut him doon lest he pull your huse doon. Another friend of moine is a youngster of great promise. I do not venture to prophesie that he'll lick or surpass the ither ones I've named, but he'll run em varry clase. Then thers that Edward Moorhen. I knaws that he hes mony detractors and such loike, but properly treated and in a sootable soil he'll flourish loike a green Baiy tree. I'd loike to poise the chaps as says he'll not open, for he wull as weel as ony o' the best. Among the loights thers that ere French Madame Rothschild, which canna be beat here or

elsewhere according to my judgement. It has, however, one grand defect which I've observed the new sorts lately sent out from France generally have, and that is want of perfume. It has no more smell than an artificial one in a glass case, but in colour and form 'tis often like a Camellia. 'Tis a good autumn variety also, which many aren't.

As for them beautiful Teas which I have seen at shows, I can do nowt w' em in this climate unless I have a hoose to grow em in; and this I cannot have, for there's little to earn and money to keep. A friend of mine who has a wee bit of a stroocture nor bigger than a henhouse grows in it wonderfu Salamanders and Bulgaviles and Enoch's Amazons and sich like—[We presume our correspondent means Allamandas, Bougainvilleas, and Eucharis amazonica.—Eds.]—never looks at a Tea Rose. I says to him, says I, "Friend Manchester, whoy doant ye turn your annds to Tea Roses, sich as we seed those southron chaps shaw at t' Cristal Palace, when me and Betsy and your missus went by cheap trip to Lunnon, sich as Maria bran boots, Sovereign's Delight, and Catherine Mermaid—[Here we suppose Marie Van Houtte, Souvenir d'Elise, and Catherine Mermet are alluded to.—Eds.]—and Clath of Goold. Them's the stuff to coltivate; foine they be, and grander than they stoave plants." But he wulln't agree. And noo I've tauld ye all I mane to, onless, as I've said afore, you mak it warth me whole.—YORKSHIRE TYKE.

## THE WESTMINSTER AQUARIUM AND SUMMER AND WINTER GARDEN.

I VERY much regret to inform you that the large fruit show which was arranged for the 4th and 5th of October next will not take place, owing to a change in the directorate. This has only come to my knowledge this afternoon, and I have therefore taken the earliest opportunity of letting the exhibitors know this by advertisement and otherwise. No one can regret this more than I do, for I feel sure it will be a great disappointment to many who will have made considerable preparations for it, and I confidently looked forward to seeing at Westminster in October one of the largest and best fruit shows ever held in London.

I have no doubt the flower and fruit shows will be again held at Westminster next year. I did my very best to make them a success this year, and I hope to have the pleasure of again meeting all the exhibitors who so well supported me with their grand exhibits of flowers and fruit, and I take this opportunity of thanking them all for the assistances they gave me.—JOHN WILLS, Royal Exotic Nursery, South Kensington.

## FILBERTS.

WE, in common with other editors, observe that topics seem at times to be epidemic; many letters reach us asking for information on one and the same subject. Just now the Filbert is brought before us by several correspondents, and one from Kent, we think, could tell us more than we can tell her. The following notes include the information required by all our querists, and we are indebted for them to Phillips's "Companion for the Orchard" and Dr. Hogg's "Fruit Manual."

"Filberts were originally brought out of Pontus into Nalolia and Greece, and were, therefore, called Pontic Nuts; from thence they were procured by the Romans, and brought into Italy, where they acquired the name of Abellan, or Avellan Nuts, from Abella or Avella, a town of Campania, where the best were cultivated (*Pliny*, b. xv. c. 22), and from thence arose the French name Aveline.

"When first known in this country they were called Nuts with Full Beards, to distinguish them from the common Hazel nut, as it will be observed that the husk or covering of this nut resembles a man's full beard; this was first corrupted into Filbeard and Filberd, and from thence into Filbert.

"These nuts still continue to be cultivated in the neighbourhood of Avelino, and, according to Mr. Swinburn's account, the whole face of the neighbouring valley is covered with them, and which in good years brings in a profit of 60,000 ducats (£11,250).

"The inhabitants of Avelino refresh the roots of these trees with new earth, and prune off the straggling shoots with great attention. Evelyn tells us in his 'Sylva,' that his family name was derived from Avelin—I find (says he) some ancient records and deeds in my custody, where my ancestors' names were written Avelan, alias Evelyn, generally."

"Frizzled Filbert (Frizzled Nut; Cape Nut).—Husk hairy,

twice as long as the nut, deeply frizzled, and spreading open at the mouth. Nut small, oblong, and flattened. Shell thick. Kernel full. This is rather a late variety. The tree is an excellent bearer, and the nuts are produced in clusters.

"Lambert's Filbert (Kentish Cob; Filbert Cob).—Husk nearly smooth, longer than the nut, and very slightly cut round the margin. Nut large, oblong, and somewhat compressed. Shell pretty thick, of a brown colour. Kernel full, and very richly flavoured. This is perhaps the best of all the nuts. The tree is a most abundant bearer; some of the nuts are upwards of an inch in length, and they have, with care, been kept for four years. It is only after being kept for some time that their full richness of flavour is obtained.

"I am not aware whether this was raised or only introduced by Mr. Aylmer Bourke Lambert, of Boynton, Wiltshire; but it is through him that it first was brought to the notice of the Horticultural Society about the year 1812. It is improperly called Kentish Cob, for the true Cobs are roundish thick-shelled nuts, and it is not many years since it was grown in the orchards of that county, the only varieties previously cultivated being the Red and White Filberts. As an evidence that it is of comparatively recent introduction it is not mentioned by Forsyth or Rogers.

"Purple Filbert (Purple-leaved).—This differs from the Red Filbert in having the leaves of a dark blood-red colour, like those of the Purple Beech. The fruit is similar to, and quite as good as, that of the Red Filbert, and is of a deep purple colour. It is, therefore, not only valuable as an ornamental shrub, but produces excellent fruit.

"Red Filbert (Red Hazel).—Husk hairy, longer than the nut. Nut of medium size, ovate. Shell thick. Kernel full, covered with a red skin.

"White Filbert (Wrotham Park).—Husk hairy, longer than the nut, round the apex of which it is contracted. Nut medium-sized, ovate. Shell thick. Kernel full, and covered with a white skin."

## EARLY ROSE POTATO.

"MARKET GARDENER" need not be afraid to advocate the planting of Early Rose Potato in rich or even wet garden ground, for it succeeds admirably. My soil is about as retentive of moisture and as rich as it can possibly be, and having grown Early Rose for years I can testify that the more I know of it the better I like it. The crop this season is simply prodigious, and the quality unsurpassable. Let me recommend those who now abuse it to try it again. Plant early, dig early, consume early; and when they have finished and have to take to other Potatoes I think they will have to admit that Early Rose is equal to any, and the best early Potato grown. But it will not keep. Eat as you dig if possible, but if you must lift and store do not let the tubers lie exposed to the air a moment longer than necessary. Put them away fresh as they come from the earth into layers of dry soil or sand, and use them before you commence other sorts.

Late Rose seems to be the same Potato, with good keeping qualities. It ripens about a month later than the other, and is a most valuable variety. It does with me as to cropping and quality quite as well as its early sister.

Snowflake is also first-rate here, and very handsome. In fact in this locality the Americans are fast driving all other Potatoes out of the fields and gardens. While on the exhibition table no others appear to have a chance against them.—R. W. BEACHEY.

THIS Potato has been with me this season, as "A MARKET GROWER" describes, "of unsurpassable quality, and even preferable as a 'floury' or 'mealy' Potato to several of our standard varieties. It has been condemned here in previous seasons, and our soil is of a sandy poor nature, but the excessive drought and heat, in my opinion, have had more to do with improving its quality than anything else. Although not a reliable variety as a table Potato, it is nevertheless useful for the kitchen, being both early and prolific.—J. W. MOORMAN.

## BOTANICAL NAMES.

Most horticulturists, probably, have been asked the name of a plant by some visitor. The answer being given, the reply is, "Who can recollect such long words? Why not give the plant an English name?" And who can understand the English name when it comes? More Englishmen will understand

what plant is meant by *Salvia patens* than by *Eglantine*, *Harebell*, or *Culverkeys*, all of which have lately been made subjects of inquiry.

I was led into this train of thought by reading the "Aspects of Nature" in p. 188. In my younger days I rambled much over the three kingdoms botanising, and met, no doubt, many Rambling Widows, but I do not recognise the plant so named, which the authoress found at Broadstairs. Perhaps you will favour your readers with the name, not in plain English, but in plain Latin, and then they can refer to any botanical catalogue for particulars of the plant.—G. S.

[It is desirable to state both the botanical name and the popular name of a plant. Probably "Rambling Widow" is the *Ramping Fumitory*, *Fumaria capreolata*.]

### NEW BOOK.

*The Grape Vine.* By JOSEPH MEREDITH. London: George Philip, Son, & Nephew, 32, Fleet Street.

MR. MEREDITH has been such a successful grower of Grapes that a record of his practice cannot but be useful and reliable. This practice he now places before the public in a small and handsome volume. We have glanced through this volume, and, as we anticipated, have found nothing particularly new or startling. Mr. Meredith has achieved success in culture by the adoption of means which are at the command of a majority of Grape-growers. Attention to small details, and an intelligent appreciation of the nature of the Vine and its requirements during its different stages of growth, are the principal elements which have contributed to the success of which this little book is the outcome.

The volume contains figures of vineries, with hints on construction, heating, and the general management of the Vine under different systems of culture. The chapters are short and plainly written. Their nature will be best understood from a few extracts. On border-making Mr. Meredith states—

"The deeper the borders are made, the more care is necessary in forming them. Where there is plenty of good composition to be had, and other necessary materials for drainage, a border may be made to the depth of 5 or 6 feet with advantage. As a rule, I recommend borders to be made about 3 feet deep. Shallow borders I do not advise, as they are apt to get too dry. Where hot-water pipes or fermenting materials are used in chambers or vaults underneath the Vine borders they require careful watching, as they sometimes get very dry, especially when hot-water pipes are applied. They do not require watering so often where the fermenting materials are made use of for bottom heat.

"Where it is convenient, I recommend the construction of Vine borders nearly altogether above the level of the garden walks. They may adjoin the range of vineries, and be made to assume a terrace-like appearance, more especially in cold and damp situations. I have done this many times, and with great success. The majority of Vine borders are on a level with the walks, while many are even below it; in the latter case they form a sort of cesspool for draining the land around them. Where the substratum is a cold, wet swamp, the houses and borders should not be on a low level. Where the formation is chalk or gravel, the borders may be made about three parts below the level of the walks, which will prevent evaporation going on too rapidly."

On the packing of Grapes for long journeys the author writes—

"There are several ways of packing Grapes for travelling. I recommend that very large bunches should be packed in very dry sweet wheat bran. Smaller bunches may be packed in stiff cartridge paper, as closely as possible without squeezing the berries. After tying each bunch neatly, pack the bunch or bunches tight together in a box with clean, dry, chopped wheat straw, taking care to fill up every crevice, which may be done with the fingers; and before putting the lid on, the chopped straw should be gently pressed down, so that if the box does happen to get knocked about on the journey the Grapes will not often get injured, and will arrive at their journey's end with nearly all the bloom on."

On the destruction of insects the following practice is detailed. For destroying red spider—

"As soon as the Grapes have nearly finished stoning, I mix unslaked lime with sulphur of the best quality and water, in the following proportions:—One medium-sized lump of lime to a bucketful of water and 2 lbs. of sulphur; stir and mix it all together, making it the thickness of paint; then with a whitewash brush paint about two-thirds of the surface of the hot-water pipes or flues. I have adopted another plan with success—viz., pouring cold water on the pipes and flues, and then dredging

them with as much powdered sulphur as can be made to stick on the pipes, but only a slight scattering on the flues. Care must be taken that the flues are not made too hot, as they are liable to set the sulphur on fire, which would destroy both fruit and foliage. Choose a still night for the operation. If the atmosphere is moist and dull, so much the better; the fumes then stay longer in the house, and are, therefore, more dense. I advise to begin about four o'clock in the afternoon to push on the fire, getting the pipes very hot by the time the sun has gone down, so as to raise the temperature the first night to 85° at eleven or twelve o'clock at night; but this temperature must not be exceeded. Examine the leaves carefully next morning with a magnifying glass. This will enable you to find out whether the spiders are destroyed or not; if not, repeat the process the following evening, raising the temperature, however, to 90°. If the enemy still remains, try again the third evening, keeping the temperature the same; and if these directions have been adhered to, it will be found that few insects will remain alive. The temperature must be carefully watched, so that it does not get higher than 90°."

For the destruction of thrips sponging the foliage with soft soap and tobacco water, also fumigating, is recommended. In this chapter appears the following—

"Some gardeners, in order to get rid of this pest, begin, after the Vines are pruned, to strip off all the bark; and I have seen some go so far as also to scrape the Vines, which I consider a most unnatural operation. Besides this, I have seen a mixture applied, in which soft soap and turpentine predominated. I have also known inexperienced people dress the Vines all over with linseed oil, the consequence being that the oil penetrated the stems until it almost killed them; and four or five years were spent in the endeavour to bring the Vines round again into a state of fruitfulness, with no result. In my opinion, the bark ought not to be stripped off, nor should the stems be afterwards scraped. It will be easily understood that the scorching rays of the sun act very powerfully on Vines deprived of bark—in fact, the bark is their natural clothing. Loose bark hanging a foot or two from the stem may, of course, be cut off; but the Vine should not be scraped nor the bark peeled off, as is often done. Notice how noble our forest trees look with their beautiful bark, protecting the rising and descending sap. I have seen horses eating the bark off trees, but as soon as the bark is removed the tree begins to die."

For killing mealy bug the author states briefly that—

"If spirits of naphtha be applied carefully with a fine camel's-hair brush, the least touch will kill the insect. After using the spirits I recommend sponging the plant with a little soft soap and water. If these precautions are repeated once a week or fortnight, as may seem necessary, it may be kept under control. I would also advise to give the house containing the fruit or plants a good cleansing once a year at least, and a coat of paint, or two coats if necessary."

The volume closes with a calendar of operations for every month in the year, which is similar, however, to the advice which is given weekly in the columns of the gardening press. It is a useful book, but not superior to others on the same subject already in circulation, and the question arises, Was another volume on the "Grape Vine" wanted? We leave that question for the public to answer. The extracts given will enable them to judge of the book, and it only remains to say that it contains about ninety pages of widely printed matter, printed well it must be added, on stout toned paper, each page having an ornamental border of Vines, shadowing the appearance of too many Vines now growing in having all the bunches at the top of the rods.

### STOCKS FOR ROSES.

MUCH has been written about Rose stocks. I find by experience that a stock which does well in one locality will not flourish in another; and if an amateur intends to exhibit blooms well during most seasons he must have Roses on different stocks. Seasons have great influence over stocks, and in one season we find the Briar and the next the Manetti stock superior.

As a rule mildew does not attack the Rose on the Briar so soon as on the Manetti, nor do late spring frosts nip the Rose so severely on the Briar as on the Manetti. Cultivated Briars are useful for all the thin-skinned varieties, but all the thick-skinned varieties, as a rule, flourish as well on the Manetti as any other stock, and no stock can furnish sap so quickly as the Manetti when the season suits it. No Roses are so grand as those that come from the Manetti for fullness, colour, freshness, and perfection of form.

It is a great mistake to discard a stock which is proved use

ful for the sake of something new. I have known, for instance, "old hands" dig up good established plants to plant others on a new stock, and afterwards regret committing the error. The seedling Briar is a good stock for some varieties and some seasons, but I have seen Roses exhibited on this stock as dull-looking this season as blooms from other stocks.

For hardy Tea Roses one of the best stocks is the cultivated Briar, either dwarfs or low Briars of 18 inches above ground. This is a grand stock, and if I was only allowed one stock for all Roses, places, and purposes I should select the cultivated Briar young and healthy. I do not know anything to surpass it. It grows Roses of sterling quality, and is worthy of recommendation.—H. MERRYWEATHER, *Southwell*.

### COMMELINA TUBEROSA.

THE Spiderworts have many representatives, widely diverse in their habits, character, and appearance, as may be expected when we note the great geographical range of their habitats. They are found in North and South America, in India, Australia, and in the territory of the Cape of Good Hope. There

Fig. 35.—*Commelina tuberosa*.

are annuals, herbaceous perennials, and stove, greenhouse, and hardy trailers. The fleshy roots or rhizomes of some of the species are eatable when cooked. Kämpfer has stated that ultramarine is prepared from the beautiful blue flowers of *C. communis*.

The tubercles of the species figured abound in starch. It is, however, as an ornamental plant that it is primarily noticed. Its flowers are of a rich blue, and the habit of the plant is pleasing. Being a native of Mexico it is strictly speaking a stove plant, but it flourishes well in the garden during the summer. In the autumn the roots should be taken up and stored like Dahlias. This species only grows about a foot in height, and is not seen so frequently as its merits deserve. Tubers are generally ready for sale towards the end of October, and should be stored in sand, starting them in spring in heat, subsequently hardening the plants and planting them out; or they may be allowed to flower in the pots. The flowers continue long in beauty, and are useful for cutting, their rich colour being always admired. Plants may also be raised from seed.

The genus was named in honour of the Dutch botanists J. and G. Commelin. *C. tuberosa* was introduced in 1732, and flowered in the garden of Dr. Sherrard at Eltham in that year.—W. J. S.

### LILIUM AURATUM.

IN your number published on the 7th inst. you remarked on the *Lilium auratum*, showing the great advantage planting-out has over pot culture. I have seen it grown well in pots, but to see it in perfection planting-out is decidedly the best mode

of culture. It is perfectly hardy, and after planting little care is given. Digging about the plants I have never done, as I consider it would be injurious.

Four years ago I made a large *Rhododendron* bed; this I had trenched 2½ feet deep, filling it with sandy loam and peat, and among it a quantity of white sand. This mixture Mr. Waterer of Knap Hill assured me, when I wrote for the plants, would suit them well, and it has proved so. When he replied to my order he said, "Why not plant among them some *Lilium auratum*?" I adopted the suggestion, and the first year after planting they made a good display, and every year increasing in strength and numbers of flowers, and some among them of the most beautiful varieties. The bulbs have never been removed since, and they are liberally watered in dry weather. This year they commenced blooming about the middle of July, and in August they were very grand. One clump more than 7 feet high had 121 blooms on it; many had thirty, forty, and more. Being different varieties their blooming has continued, and at the present time (September 11th) they are still very beautiful, some stems having twenty, thirty, and forty blooms on, and they perfume the air all round.—T. CLEMENTS, *Pains Hill*.

### SEASIDE PLANTS ON THE LANCASHIRE COAST.

ALONG the whole Lancashire coast the gales beat with considerable severity; and at the watering places, such as Fleetwood, Blackpool, and Lytham, lodging-house proprietors, who vie with each other in trying to make their gardens and house fronts attractive by planting shrubs and climbers, have evidently a difficulty in selecting proper subjects for the purpose. At Lytham, which presents a long frontage of handsome villas to the wide estuary of the Kiddle, up which the tide rushes about as rapidly as it does up the Solway, and often accompanied by a gale, the effects of the blast upon the different kinds of trees and shrubs are very apparent. Deciduous trees, such as the Elm, Beech, Laburnum, Plane, Hazel, &c., make some growth annually, but their appearance is completely spoilt by the blast soon after they come into leaf. At present (the second week in August) they are as brown and withered-looking as if a black frost had passed over them, and they have been in this state during the most of the summer, we understand; and this state of things is not confined to the beach, for inside the town, within the shelter of the houses, they are little better. There is only one notable exception among the deciduous class, and that is the common Willow. In the apparently dry sandy soil it grows amazingly, and is always green and luxuriant close to the sea, and is in consequence extensively planted for sheltering purposes. In the extensive Lowther Gardens, presented to the town by Colonel Clifton of Clifton Hall, it is employed almost exclusively for sheltering the more tender subjects, being used as the background everywhere. It gives rather a sameness of aspect to the grounds, but the sweeping lines of Willows have nevertheless a highly ornamental effect, and we were never so much impressed with its value as an ornamental tree before.

It is amongst the evergreens, however, that we find the most suitable subjects. Sweet Bays, Golden Hollies, Arbutus, Laurustinus, Evergreen Oaks, and Aucubas, are everywhere the most telling objects on the beach, and they seem to suffer but little; in fact, the Bays and Laurustinus thrive and grow to tree-like dimensions. The Laurel does not seem to like the sea breeze, but the Laurustinus is an excellent substitute. Among climbers the Ivy and Passiflora cærulea are the best. The last is growing on some of the house fronts within fifty or sixty paces of high-water mark as rampantly as a hardy Clematis, and is fairly smothered with flowers; we never saw it in such luxuriance before. The Fuchsia, both hardy and tender varieties, grows well during the summer, but is invariably cut down to the ground by frosts in winter. On the Isle of Man, about fifty miles distant, and almost within sight, it grows 20 feet high, and is nearly evergreen. Only the other day we noticed there in a Fuchsia hedge limbs nearly as thick as one's leg, with great spreading branches hanging over into the highway; so much for the difference of climate.—J. S. (in *The Gardener*).

DAHLIAS.—In our report of the Horticultural Meeting at South Kensington on the 6th inst. it appears as if the twelve very fine Dahlias which are named were included in Mr.

Turner's collections, whereas they were exhibited by Mr. G. Smith, and a vote of thanks given for them.

### THE DROUGHT—ITS LESSONS.

THE degree of hardness of any plant can only correctly be ascertained when it is in full health and when it grows in a soil and situation to which its nature is suited. Insufficient knowledge of these is the cause of the conflicting statements which are published respecting the same plant in isothermal sections.

The effects of drought are frequently mistaken for those of cold. Deprived of moisture a plant is deprived of food, and thus half starved; though lingering through the summer it succumbs to the severity of winter. Excessive richness as well as excessive poverty of soil may cause the death of plants during winter by inducing a superabundant exhaustive growth which they can neither mature nor support.

But we have trees and shrubs, herbaceous plants and annuals, that are adapted to every variety of soil and condition of weather, and it is a knowledge of such adaptation that enables some, let the season be what it may, to preserve their gardens in comparative beauty.

The present summer, the hottest and driest we have ever experienced, has wrought great mischief in those grounds wherein such relations have been entirely ignored, and only those who presume to believe that a liberal and prompt expenditure of money can be made fully as effectual in the reparation of damages as horticultural observation and study, will fail to be instructed by its lessons.

It is true the present season has been exceptional and severe droughts local, but it is just these exceptional seasons that we should provide against in the selection and distribution of our so-called hardy plants. Let extremes of heat or cold, wet or drought, occur but once in ten years, it suffices to kill or sadly disfigure the beautiful forms of many trees and shrubs that under our care have grown to full maturity, and that constitute, it may be, those very objects of our grounds to which we have become most attached. In many affairs of life we may be guided by rules—in this phase of horticulture we should be guided by exceptions.

While now we see plants green and vigorous growing in sandy soils or high dry situations, whether in private grounds, in woods, or fields, we may safely conclude that the same varieties are as well adapted to the highest driest parts of our own grounds, and that after cultivating them for years they will not in their mature beauty be destroyed by drought, either directly or by being so weakened as not to be able to endure the cold of the ensuing winter. So likewise, when we see plants suffering in such situations, we may be sure that they are not adapted to each other in any other locality. This is but one of the lessons of the drought; but it is well worth the learning, and requires but little inconvenience or effort.

To apply these remarks to floriculture, we have found that many plants that it has been deemed necessary to water daily during the dry hot weather of other summers, have fared just as well during the present drought without being watered at all. We may point out especially *Plumbago capensis*, that though placed in the upper tier of a rockwork exposed to the sun nearly all day and never watered, has bloomed more profusely than ever before, while the foliage is perfectly green and healthy. Had we watered this plant as in previous seasons, the impression could not be avoided that its preservation was due to the water and not to any special adaptation of the plant to the driest of situations. Thus we are enabled to add one of the most charming of plants to the scanty list of those which are perfectly adapted to rockeries.

The *Eucalyptus globulus*, seeds of which were sown last December 3rd, is now 3 feet high and of about the same breadth, with widely-spreading branches, and opposite, nearly sessile leaves that, in those two respects, recall the Honey-suckle. Though this has received no water, there is not one discoloured leaf upon our several specimens, and the glaucous bloom that covers the young wood and leaves gives it a most refreshing appearance. The new shoots are furrowed and sharply four-angled. These furrows and angles gradually disappear until the ripened wood is as smooth and round as a ring. The bluish-green bloom of the new shoots is readily rubbed off with the hand, and should it be moistened with perspiration, it instantly presents the appearance of being suffused in blood. No insect has disturbed our plants, and we should think that the *Eucalyptus globulus*, cut back from year

to year, would become a favourite among tender subtropical plants, particularly where the plot is located in a dry situation.

As enduring drought remarkably well, though worthy of general cultivation for other reasons, we call attention to *Plumbago Larpentæ*. This is an old hardy half-herbaceous shrub, which is as distinct from *P. capensis* as two plants of the same genus can be. Its habit is compact, leaves small, spatulate, and flowers of a deep violet in dense heads. The flowers are the size of the *Verbena* and, like them, salver-shaped. There is but one thing that mars its beauty—viz., the flowers do not open simultaneously, and they persist after their beauty has faded and form no very bright surrounding to those blooming after. Its hardness, compactness, endurance of drought, and possession of a colour with which our gardens are never surfeited, are, however, characteristics that may commend its use to all, if not for the showiest of our borders, at least for those parts most liable to suffer from drought.

Among Vines less commonly cultivated that thrive in dry places is the Mountain Fringe, *Adumia cirrhosa*. The leaflets of this Vine are peculiar, bearing no petiolar attachment and being every one of a different shape. Common in our western woods, where it is found mostly in wet places, a dry position is the last thought of. It is a biennial, and its growth the first season bears no resemblance to a Vine, but rather to a Fern, having thrice-pinnate leaves and variously lobed little leaflets. Beside *Plumbago capensis* in the rockery it flourishes finely.

All of us know of the Matrimony Vine (*Lycium vulgare* or *barbarum*), and many readers will exclaim, "We know enough of it!" It should, indeed, be excluded from companionship with all other plants on account of its spreading roots, which take possession of the ground and throw up suckers for an unwarrantable distance. But it is a gem in its place. Planted under the eaves of houses, at the base of old stumps and rocks, upon sandy banks, or in those out-of-the-way corners which it is desirable to fill with verdure that will require little or no care—nothing is better. A single specimen of this shrub, for it is not a Vine, grows in our own grounds close to a brick foundation, entirely exposed to the sun from morning till night, without having received one drop of water for three months or more. It is cut back every spring, so that with the bushy form thus forced—the drooping branches and its contrast of small and large leaves—so entirely is it the right plant in the right place, that from despising it as it was once grown among other things, we now prize the Matrimony Vine as all of us finally prize plants that fully respond to all that is asked of them.

A sickly plant, however rare or costly, is far from ornamental, and grounds which are planted without regard to adaptation of soil and situation will fail to realise the expectations of the most tasteful arrangement.

Taste alone may correctly point out where trees and shrubs should be planted, either as single specimens or in groups; where the flower borders and beds should be located; where the lawn should be unbroken in its velvety green; where vistas should exist to lend the charm of mystery and picturesqueness to all. But a knowledge of the conditions under which plants alone can mature their fulness of beauty is indispensable to the development and permanence of the design.

A part of this may be learned by an observance of the effects of droughts.—(*Rural New Yorker*.)

### PRESERVATION OF WOODWORK.

ALL country residents, and especially gardeners and farmers, have to expose woodwork in some form to alternate states of wetness and dryness. To preserve it as long as possible is of importance, and many processes have been recommended. We knew the posts of two field gates inserted at the same time. The ends of two were charred before being buried, the ends of the other two were tarred. The charred posts were still firm for years after the others had been renewed.

The *English Mechanic* states that in a paper communicated to a meeting of engineers of the "Verein Deutscher Eisenbahnverwaltungen," M. Fünk furnishes some data on the subject, which are of considerable practical interest.

"According to observations which were made partly on the Cologne-Minden line and partly on the Hanoverian State railways, pine sleepers impregnated with chloride of zinc require, after twenty-one years' use, an exchange to the extent of 31 per cent.; beech sleepers impregnated with creosote, after twenty-

two years' use, an exchange of 46 per cent.; oak sleepers impregnated with chloride of zinc, after the same period, an exchange of 20.7 per cent. In all the cases observed the conditions were very favourable, the bedding material being good and pure and perfectly permeable. Specimens cut from sleepers which after the times indicated still remained on the line, showed perfectly sound surfaces of cross section.

"Along with these results obtained on German railways with impregnated wooden sleepers, M. Huber communicates in an Austrian journal the results of observations made for a number of years back on the Kaiser Ferdinands Nordbahn in Austria. The amount of renewal necessary was: In unimpregnated oak sleepers, after twelve years' use, 74.48 per cent.; in oak sleepers impregnated with chloride of zinc, after seven years, 3.29 per cent.; in oak sleepers impregnated with tar-oil containing creosote, after six years, 0.09 per cent.; in pine sleepers impregnated with chloride of zinc, after seven years, 4.46 per cent.

"The impregnated pine sleepers were placed in 1869 at the stations of the Mährisch-Schlesischen Nordbahn. Since the years 1869-70 there have been laid on the Kaiser Ferdinands Nordbahn only oak sleepers, which were impregnated either with chloride of zinc or with tar-oil containing creosote."

### WIMBLEDON HOUSE.—No. 1.

THE RESIDENCE OF SIR HENRY W. PEEK, BART., M.P.

FEW public men have a higher reputation for diligence in business and for the active support given to every good work than Sir Henry Peek. His name is familiar to all who are interested in the social amelioration of the country, for there are few organisations for the public good which do not have the benefit of his patronage and assistance. As in general so also in local measures having a beneficial tendency Sir Henry Peek can, amid his parliamentary and other duties, find time to preside at meetings for the advancement of, and distribute prizes which are offered for the encouragement of cottage gardening, and he is ever ready to foster and promote a taste for those wholesome pursuits which are to be found in a garden however small it may be. Besides a disposition to support any measure having for its object the increase of knowledge on matters pertaining to gardening, he, with the aid of Lady Peek, is assiduous in inculcating lessons of humanity in the animal world.

As proof of Sir Henry's readiness to aid in the works mentioned may be cited his recent distribution of prizes on an extensive scale for cottage gardening on the Shaftesbury Park estate, where small gardens are numerous, and are managed with great taste; and, as the character of a man is perhaps best seen in small things, we may note also the privilege which Sir Henry affords to the gardeners of the district of meeting once a fortnight during the long winter evenings in the young men's rooms at his gardens, where the men not only have the advantage of profitable and congenial discussion, but are further generously supplied with an ample social meal to render their enjoyment complete. This act of kindness—which should be, and doubtless is, highly appreciated—dates not from yesterday, for the meetings have been established for some years, and from them has sprung the more extensive Gardeners' Society which has been frequently mentioned in these pages. The public Society has not been instituted to supplant the private gatherings, but, on the contrary, there is every probability of the latter being better attended than before, in consequence of the impetus that has been given by the larger meetings to the promotion of unity amongst gardeners and the discussion of subjects with which they are connected. The resuscitation of these useful meetings is in a great measure due to the energy of Sir Henry's head gardener, Mr. Ollerhead, who has zealously endeavoured to render them successful, so that they may in the fullest manner possible answer the purpose for which they were established.

Sir Henry Peek is also a patron of horticulture on an extensive scale and in its higher branches. When we find a gentleman expending £30,000 in the erection of glass structures, a gardener's cottage, young men's rooms, stabling, and other adjuncts of his estate which are under the control of the gardener, it is sufficient evidence that the practice of the art of gardening is not neglected. On that point, however, judgment shall not be deduced from inference, but we will look at things as they are and note the garden, its condition and management, and thus decide how far such are worthy of a liberal owner and the comparatively young manager now in charge. It may, how-

ever, be mentioned that if Mr. Ollerhead is young in years for such a position, his practice has been derived from good gardens in England and Scotland, and "four years at Trentham," if coupled with intelligence and activity, must always weigh heavily in the scale of a man's qualifications.

Wimbledon House—its grounds and gardens—have, it appears, long enjoyed the fostering care of owners having horticultural tastes and inclinations. This place is figured and described in London's "Villa Gardener," from which the following extract is taken:—"This estate, which once belonged to the celebrated Bond Hopkins, Esq., and was laid out for him about the middle of the last century, consists of about 100 acres of table land, slightly varied on the surface, not by undulations, bold swells, deep valleys, or precipitous declivities, but by unconnected hollows or large gullies—of little beauty in themselves, but capable of producing considerable effect when filled with water, as the principal one now is. The chief merit of the place as a suburban residence consists in its completeness, the whole lying compactly within a ring fence, and there being a most commodious mansion with complete domestic offices, a park, a farm (including a dairy and a poultry-yard), a kitchen garden, and a flower garden; the latter, perhaps, unrivalled in the neighbourhood of London for the number of species and varieties of herbaceous plants that it contains. Mrs. Marryatt (the successor of Mr. Hopkins, and the predecessor of the present owner) has long been an enthusiastic admirer of flowers, and especially of such as are sufficiently hardy to make a display in the flower garden. She also maintains a good collection of greenhouse and hothouse plants; and many of these, as well as hardy plants, have flowered at Wimbledon House for the first time in England. Among the more beautiful and remarkable greenhouse plants which have flowered for the first time at Wimbledon is the *Tasconia pinatistipula*, one of the most elegant, and at the same time singular, of climbing shrubs." In addition to the plant above named may now be seen in the aquatic house the original plant of *Tabernaemontana coronaria*, which was introduced from the East Indies in 1770.

Mr. Bond Hopkins sold Wimbledon House to Mons. de Calonne, then a French political refugee. The estate was subsequently purchased by the Right Hon. Earl Gower, afterwards Marquis of Stafford. The Marquis sold it in 1798 to Sir Stephen Lushington. In 1810 it became the retreat of Louis Joseph de Bourbon Prince of Conde, who married while in England the Princess Dowager de Monaco, who died at Wimbledon in 1813. After writing the life of his illustrious ancestor, the great Conde, the Prince died in Paris in 1818, his son modestly refusing to take the title, as considering himself unworthy to succeed his father, "who so long commanded the French nobility in their glorious exertions to defend the cause of monarchy." In 1815 the estate became the property of Joseph Marryatt, Esq., who died in 1824. His widow Mrs. Marryatt, F.H.S., continued to reside here until 1854, and devoted much of her time and money to the formation and cultivation of her beautiful gardens, and in introducing new and rare trees and plants. After the death of Mrs. Marryatt (who was the mother of our celebrated novelist Capt. Marryatt), the estate was in Chancery for two years, when it was purchased by the present proprietor, who has not been less liberal in effecting improvements than his predecessors.

A lofty and substantial brick wall very nearly encircles the estate; it was a costly fence no doubt, but certainly it is a permanent one. Within the wall are large trees, notably Elms, which, however, have been denuded of their branches as a precaution against accidents. Other trees which are especially remarkable are Evergreen Oaks. With these the place abounds, many of them having attained to gigantic timber trees. There are also good examples of the English Oak, picturesque groves of Beeches, and venerable Cedars and Yews. The soil appears to be a light loam, and within 2 feet from the surface is gravel, the bed of which is many feet in thickness. In this soil the trees named have grown freely, and apparently will continue to do for years to come, for they are in perfect health.

The park is surrounded by an enjoyable walk, which is completely embowered in foliage, principally from the Evergreen Oaks. The undergrowth of these trees is principally of *Rhododendrons*, which grow luxuriantly, the dark foliage of these evergreens being relieved here and there by a variegated Holly. Across the walk at intervals are formed rough arches of masonry after the manner of ancient ruins. Through openings in the trees are afforded picturesque glimpses of hill and vale, water

and trees; and the visitor, instead of having his standpoint almost within cannon shot of London, may imagine himself as being a hundred miles distant from any "murky town." This marginal walk conducts us from the house to the deer park, a small enclosure stocked with handsome specimens of fleet and timid animals. In this enclosure is a Cork Tree (*Quercus suber*) 50 feet high, and a trunk girthing 9 feet.

From this park we reach the lake. At its end is an island on which, nestling amongst the trees, is an "old ruin," which the "guide," with an air of delicious nonchalance, suggested "might have had something to do with the monks," but after a glance at the arches, &c., he received a reply, "and it might not." It appears, however, that it was used as a Catholic chapel by the Prince of Conde. The dimensions of the ruin are 20 feet by 12 feet inside measure. The lake is also in a great measure artificial. It is about seven acres in extent, and is highly ornamental both by its form and surroundings and

the great variety of fancy waterfowls which adorn its surface. This lake has been formed by holding up the water in one of large gullies. The embankment is rather a formidable affair, exceeding 100 yards in length, and is of great substance. Its slope to the lower ground is very deep, and is planted with trees, and between these and the water is a broad velvety promenade of perfectly kept lawn. No part of the grounds is more attractive than this cool and secluded retreat. By the margin of this lake is a remarkable example of an Ivy-clad Oak. This tree, roughly girthed, measures 27 feet round its stem at 4 feet from the ground, and resembles a gigantic Ivy bush, for not only is every branch of the tree densely enveloped with Ivy, but it towers aloft far above the Oak in massive clusters. The Oak is so completely hidden that only two tiny sprays of it are to be seen, and these are perfectly healthy. In striking contrast to the dark drapery of this venerable monarch is a contiguous specimen of *Catalpa syriaca* with cheerful, large, light

Fig. 36.—WIMBLETON HOUSE—THE FLOWER GARDEN.

green foliage. This also is a large tree, and is rendered the more ornamental by its thousands of seed pods, almost exactly resembling those of *Vanilla aromatica*. The *Catalpa* is a noble tree, hardy, distinct, and attractive, and it is a little surprising that it is not more freely planted in pleasure grounds. The golden-leaved variety of it is very conspicuous; young plants may now be seen doing good service in Battersea Park.

Passing by other lakes and other islands we arrive at a grotto which the "guide" might well have suggested that it "might have had something to do with the elves and fairies." This is a small but wonderful work of art, and in its construction and ornamentation much patience, taste, and labour have been exercised. Tens of thousands of shells adorn its roof and clothe the stalactitic protuberances which descend from it. The sides are rugged and made to form miniature caverns, out of one of which a crocodile protrudes its ugly head. Mirrors are placed in corners to resemble water, and in the subdued light—for light is admitted only by the door—the effect produced is such as to startle the visitor seeing it for the first time, and to extort from him the spontaneous exclamation, "How very singular and beautiful it is!" It is worthy of note and inspection.

From this point we return homewards through a grove of Wellingtonias alternately planted with Evergreen Oaks, the latter having been raised from acorns gathered and sown by

Sir Henry Peek. The Wellingtonias are large and healthy specimens, and similarly fine are other Conifers in this grove, such as *Thuja borealis*, *Cupressus*, and *Biotas*. In all probability several of these handsome shrubs will be removed to Sir Henry Peek's new residence which is now being erected in Devonshire. We have now completed the circle of this ornamental park, all round which the walks, grass verges, and lawns are well kept, and arrive at the gardens.

The first department to notice is the flower garden. This is of considerable size, and is perfectly unlike the modern flower gardens which are laid out in the present day. There are no formal designs described on geometrical principles, no spar, no Box edging, no unbroken glare of colour, no sameness to tire, no crowding to incommode. This garden was originally formed by Mrs. Marryatt, and happily it has been preserved in its integrity, and has not been defaced by "improvements" destroying its original character. Slight additions and alterations have been made, but they have been made with good judgment and taste. The modern has been blended with the ancient, the present added to the past, but in such a manner as to be subservient to the original plan—if plan it is—and not overpowering it by a violent display of the floral fashion of the hour. No small moral courage would be requisite to form a flower garden after this style now-a-days, but where such a garden exists it would be little short of

sacrilege to destroy it, and the taste prompting any radical alteration would be taste gone mad. It is a most enjoyable garden—a lawn with trees, shrubs, and flowers, a garden where at all times there is something to attract, and most times from which a posy may be gathered—a “posy of sweet-smelling flowers,” which many flower gardens of the “latest fashion” cannot supply.

A long natural hollow appears to have been selected for this garden. It is bounded on the north side by a splendid range of glass structures and a broad terrace walk, and on the south by Rhododendrons and a corresponding walk. At the west is a wall covered with Ivy and climbers, and at its foot a border of herbaceous plants, and on the east is the park. A walk traverses the entire length of the garden along the centre of the hollow, and there is also a cross walk. In the centre of the garden is a fountain partly surrounded by handsome specimens of Irish Yews, and similar specimens are growing at intervals along both sides of the walks. Entering the garden by the long walk we pass a pair of statues—the Regent Murray and Jeannie Deans. In other parts of the grounds statues of the other characters immortalised in the Waverley Novels are appropriately placed. At some distance from and on each side of the long walk are Roses trained to flat hurdles, which were designed by Mr. Ollerhead and which answer their purpose admirably. The garden is also in a great part surrounded by a lofty festoon of climbing Roses. Other festoons of Roses there are on the lawn, in one place encircling Lady Peck's herbaceous garden—a circle with eight beds converging to the centre, which are planted with old-fashioned herbaceous and alpine plants. Another and a larger example of festooning is known as the Rosery, a temple-like arrangement of climbers with Roses trying to grow in the central bed. Roses cannot well flourish when thus covered and confined; never mind, the rosery is an “established institution” of the place, and is wisely preserved for its original purpose.

On the lawn, at irregular intervals, are trees, and shrubs, and bushes which are not usually met with in such a position. Conspicuous is a splendid example of the deciduous Cypress (*Taxodium distichum*), quite a timber tree, but extremely attractive by its light green pinnate foliage. This is sometimes called *Taxodium pinnatum*, or *Cupressus disticha*. *T. pinnatum* is, however, a Mexican species, which is too tender for the English climate. *Taxodium distichum* is a very hardy and a highly ornamental tree, especially when it attains to the size of the Wimbledon specimen, which is 55 feet high, with a stem 10 feet in circumference. A deciduous Cypress is mentioned in Miller's “Gardeners' Dictionary,” which was published in 1724, as growing in the garden of Sir Abraham Junssens at Wimbledon, and as being then 30 feet in height and bearing cones. Sir Henry Peck's tree is evidently very old, but can scarcely be regarded as the tree referred to by Miller; it may be, however, the proceeds of a cone from that noteworthy specimen. Another very fine tree in this flower garden is the Twisted-leaved Willow (*Salix Babylonia crispata*), the Ring-leaved Willow. This is commonly regarded as a species under the name of *S. annularis*. This distinct variety was introduced to this country by a Mr. Vernon, a merchant at Aleppo, who afterwards retired to live at Twickenham, where the original tree was growing in 1749. This Willow is most distinct by its pendulous branchlets and convoluted foliage, and is highly ornamental. The tree in this garden is about the same height as the *Taxodium* referred to. Of lower stature, yet of large size, is *Magnolia conspicua*, and which is a splendid object in the twilight in spring, when its large white flowers appear in the distance as if floating in the air; near it is also a fine example of *M. glauca*, which is producing at the present time a few stray wax-like flowers. *Arbutus Andrachne* is also noticeable, a finer specimen being seldom met with. There is also a very old *Araucaria* divested of its lower branches, and cones of Yews “tipped with gold,” the golden variety having been grafted on the green. The Smoke, Gauze, or Wig Tree, *Rhus Cotinus*, is also represented by a large bush covered with panicles of feathery flower stalks. This distinct and ornamental deciduous shrub is not sufficiently planted. Noticeable also is an extraordinary specimen of *Cydonia japonica*. This is growing on the lawn in the form of a dense globular bush, which cannot be much less than 20 feet in diameter. Each spring it is laden with its brilliant blossoms, and then presents a gorgeous appearance. We pause also to admire a fine clump of *Cotoneaster microphylla* covered with berries; there are also some very old specimens of *Andromedas*. A bush of Ivy on the lawn, com-

mon though it may be, is attractive by its close shrub-like growth. There are also arcades of Ivy here and there of tree-like magnitude through which the visitors pass and also admire. A much less common shrub is also here, the *Comptonia asplenifolia*, sometimes called the Sweet Fern from the odour of its finely cut foliage. It belongs to the Myricaceæ or Sweet Gale family, and was named in honour of Bishop Compton, who was a great patron of horticulture. It is a North American deciduous shrub growing about 4 feet high, and is hardy, elegant, and sweet.

The above are a few of the trees and shrubs which adorn this fine old flower garden, and scattered about amongst them are large round beds of subtropical plants and flowers. There are beds of Maize, *Solanums*, *Cannas*, *Yuccas*, and such flowers as Cloves, *Delphiniums*, *Lirises*, *Petunias*, *Zinnias*, and even a bed of one of the Club Mosses, which Mr. Ollerhead states has been established by a better man than himself; for after trying all ways and periods he cannot successfully transplant it, which is somewhat unfortunate, as the hot summer has injured one portion of the bed. There is also a piece of water surrounded by rockwork and Ferns, and occupied by Water Lilies and small fancy waterfowl, and an alpine cone planted with *Cerastium*, &c., in one of the corners of the garden.

An arrangement such as described may be considered sombre, but this is obviated by a series of beds near the sides of the walks; the beds being occupied with the ordinary bedding-out plants, such as *Geraniums*, *Calceolarias*, *Coleuses*, *Centaureas*, &c., and their effect is enhanced by the bold background of the other occupants of the lawn. The *Calceolarias* have been splendid and grew luxuriantly during the hot weather. Previously to planting them the soil was removed to the depth of a foot, when a good layer of cow dung was put in and the soil placed over it. This sustained the plants and prevented the “disease” attacking them. Altogether the garden is sufficiently bright, and is particularly enjoyable by its varied attractions—a garden wherein one may wander day by day and always find something fresh, and at no time can it be considered as tame and unsightly.

But there is still a little more for those of modern tastes. At the sides of the southern terrace walk, which is divided from the flower garden proper by Rhododendrons, is a lawn, and on this lawn are a few large raised beds planted in the carpet-pattern style. These are well filled, and the designs are pleasing; yet good though they are of their kind, they look puny in comparison with the freer, bolder, easier mode of decoration beyond the shrubs. On this terrace is a rustic seat canopied with *Sophora japonica pendula*, and from this seat the view across the flower garden—the fine trees, the towering Yews, the glimpses of flowers, with the noble range of houses with a central dome as the boundary—is strikingly beautiful.

From the south-west corner of the flower garden an avenue of Elms shows the way to the manseion; a portion of this avenue is seen in the accompanying engraving, which gives a characteristic view of this excellent and ably-managed flower garden.—J. W.

### BRAZILIAN FLOWERS.

MR. T. W. HINCHLIFF, F.R.G.S., President of the Alpine Club, has recently published a “Narrative of Wanderings Around the World,” in which is given a marvellous account of the floral treasures discovered in the wilds of Brazil. The gentleman is an ardent botanist, and during the three-months stay at Palmeiras made a large collection of interesting and beautiful plants, many of which were new to science. He speaks in terms of excusable enthusiasm of “*Fuchsias* 50 or 60 feet in height, blooming from top to bottom;” of large bushes of *Abutilon venosum*, “hanging its orange bells with crimson streaks over the placid waters, close to the huge *Daturas* with their hundreds of white trumpet-shaped and sweet-scented blossoms, some of which I have found to be 16 inches in length.”

Within a day's walk from Palmeiras Mr. Hinchliff and his party gathered 250 species of Ferns, on every excursion discovering new ones to add to the list. Among them were two species of the *Lygodium*, or climbing Fern, and the rare *Hemidictyon marginatum*, “with pale-green fronds, 11 feet high, and broad pinnae, as delicate as silver paper.” In the forests each tree supports a vast variety of parasitical plants. “Orchids and Ferns; huge *Arums* with shield-like leaves, large enough to cover a man; brilliant red and yellow *Bromelias* and *Tillandsias*; epiphytes and parasites of all de-

scriptions; rope plants, creepers, trailers, climbers, mosses—all live together like a happy family far beyond the reach of man. . . . I have even seen a tall white *Amaryllis* in full blossom growing on the bough of a *Jiquitiba* nearly 100 feet above the ground." Mr. Hinchliff was told by a French botanist that a fortnight could be occupied in studying the plants on one of these gigantic trees which fall to the earth from time to time.

In the gardens of Brazil Mr. Hinchliff saw *Camellias* 15 feet high, and large enough to climb into to pluck the topmost blossoms; and *Poinsettias*, "not in the little plants which often ornament our London dinner-tables, but grown into very large bushes, on which I have found the crimson star of their floral bracts to be 2 feet in diameter." A profusion of other cultivated flowers growing in extraordinary luxuriance are mentioned by the author.

### NOTES AND GLEANINGS.

A REPETITION of the experiment of last year of an INTERNATIONAL POTATO EXHIBITION will be held in the Alexandra Palace, Muswell Hill, on Thursday and Friday, September 28th and 29th. The prizes offered amount to upwards of £140, the result of the subscriptions of the promoters, aided by a grant of £40 from the Alexandra Palace Company. The entries promise a fine display, and it is expected that fully three thousand dishes will be staged.

— LAST year we were highly favoured with FRUIT SHOWS, but this year we have now little to expect. The "International" last year at the Alexandra Palace was an excellent exhibition, and very good was the show at the Crystal Palace, while the display at South Kensington was extensive and superior. This year no show is announced at the Alexandra Palace; the schedule of the Crystal Palace show is a small one; the Royal Horticultural Society's show has collapsed, and in consequence the fruit-growing public was looking forward to the October display at the Royal Aquarium, but which is now abrogated. An announcement in our advertising columns conveys this information, which will certainly be unwelcome news to many, and a letter from the horticultural superintendent regrets it—a regret which not only many intending exhibitors will join, but which those who are interested in fruit-growing will share. We can only hope for better things next year—more fruit to show, and better facilities and encouragement for showing it.

— WE learn that the POTATO DISEASE is arriving in London, and in a form that should put purchasers on their guard, and prevent them making hasty purchases of cheap lots of tubers. It is well known by those having experience with large quantities of Potatoes, that tubers which appear sound when taken up will in the course of a week, more or less, often show the disease unmistakably, especially if they are stored in large quantities. Such is the case at present, and hurried consignments and quick sales may turn out anything but good bargains to the purchasers. The comparative lightness of the Potato crops is a sufficient guarantee that sales at cheap rates will not be forced if the produce is known to be sound and of good keeping quality. Tubers which have been hurried into railway trucks and heaped at the depôts in large quantities must be regarded with suspicion if offered at anything less than the full market value of sound produce. We are informed of more than one cheap bargain which has turned out dear to the purchaser, for in ten days after the purchase many of the tubers have been found to be affected with the disease, although they were apparently sound at the time of purchase. We have before known the disease to partake of the same peculiar and delusive character, and to a greater degree than we trust is the case at the present time.

— A VISITOR writes as follows on the planting-out of *ADIANTUM FARLEYENSE*:—"At Shipley Hall, the residence of A. M. Mundy, Esq., in Derbyshire, there is a large intermediate house planted as a rustic or natural fernery. There are scores of varieties of all the finest Ferns growing luxuriantly in it, but the most effective of all are the plants here and there of *Adiantum farleyense*. This variety is planted-out like the rest, and its large beautiful green fronds drooping over the miniature ledges of rock produce an effect which I never saw equalled with any other Fern."

— ONE of the most attractive shrubs recently introduced is *WEIGELA AMABILIS LOOYMANSI AUREA*. It is so named after Messrs. Looymans & Sons, nurserymen, Oudenbosch, Holland.

The flowers are crimson and white and attractive, but the foliage entitles it to its distinctive name "golden," for the leaves are totally yellow. The colour is stated to be but slightly altered by exposure to either sunshine or shade. A coloured drawing of the leaves and flowers is in the "Revue l'Horticulture Belge" for August.

— THE twenty-first annual EXHIBITION OF FRUIT AND CUT FLOWERS commences at the Crystal Palace to-day and continues throughout the week. Considering that it is likely to be the only fruit show held in London and its vicinity during the present autumn, the limited nature of the schedule and the small amounts offered as prizes are matters which will be generally regretted. The highest prize is £5 for ten dishes of fruit, £3 being offered as the premier award for a collection of six dishes. Other prizes in the fruit classes vary from £1 10s. to 5s. Small prizes are offered for cut flowers, and there are five classes for cottagers' vegetables. A "crush" is not anticipated.

— FROM many correspondents we have accounts of the extreme RAPIDITY OF GROWTH OF MANY AUTUMN CROPS, such as Coleworts, Spinach, Cauliflowers, Turnips, &c.; Celery, Brussels Sprouts, and the various kinds of Kales are also improving in a very satisfactory manner, and if the autumn should continue lengthy and the weather mild the scarcity of a supply of vegetables during the winter is not likely to be so great as was at one time anticipated. Weeds also grow apace, and it is as well to bear in mind that the means of checking their growth will also at the same time further the activity of the useful crops, which in the absence of hoeings and a regular moving of the surface of the soil, are deprived of much support. That vegetables can be cheap is, we fear, impossible, yet by good cultural attention the supply in most gardens will, we trust, be equal to the demand of the owners and their cooks. Dewy nights, manure water, and surface-stirrings work wonders in improving the autumn crops and preventing a scarcity of vegetables.

— WE have again visited Cleveland House to note the lasting qualities of the CARPET BEDDING which is there carried out in such perfection by Mr. Legg. Hundreds of visitors have been to criticise and admire, for none that we can hear of have been disappointed. The few who have the opportunity of seeing these beds and who have not done so, have yet time to take a lesson. If they cannot see the beds in their zenith of beauty, they may see carpet bedding as probably they have never seen it before; and if there are some who cannot admire the "style," they will yet admit the skill which is evidenced in the arrangement and finish of the beds. The gardens, we may remind our readers, are open on the afternoons of Tuesdays and Fridays, and unless frosts occur the beds will remain gay throughout the present month. They are decidedly more lasting in beauty than are beds of flowers, for while the *Geraniums*, &c., are now uninviting, the carpet beds are highly attractive. In the houses, too, there are a few plants worth looking at. Nowhere can finer, if as fine, *Crotons* be seen, and *Dipladenia Brearleyana* has now fifty flowers expanded, some of them being of a rich crimson colour and of the size and texture of *Allamandas*. This, the finest of all *Dipladenias*, was introduced by Mr. Bull, and no one has grown it better than Mr. Legg. In the stove the *Nepenthes* are attractive, one plant of *N. Rafflesiana* having nearly forty pitchers and a number of others showing. In the vineries the first crop of *Muscat of Alexandras* averages 15 to 20 lbs. per rod; the bunches are well filled, but the berries are rather small, the crop being fully too heavy. All the canes will be cut-down to the base of the rafters, others of remarkable growth being trained between them for the next year's supply. It remains to be seen how the heavy crop of this year will affect the growth of the Vines next year after the rods have been cut down. One Vine is cropped with a vengeance, it showed ninety bunches, and fifty were allowed to remain, but the Grapes are small.

— A CORRESPONDENT writes on the scarcity of TEA-SCENTED ROSES which has been recently alluded to, that the quickest mode of propagating them is to strike cuttings of the young wood in heat in spring, after the manner of striking *Verbenas*, subsequently hardening the Roses off and planting them in good soil, and in the following year dwarf flowering plants are produced of the best quality. Tea Roses, he adds, "may be thus increased by thousands and the scarcity be averted." While admitting the usefulness of the above hint, we do not suppose that the scarcity of Tea Roses is due to failures in

propagation so much as to the continual losses occurring by severe weather after the plants have become established.

— A WEEK or two ago we referred to some exceedingly fine COCKSCOMBS which had been grown by Mr. Hawes, gardener to Mrs. Rhodes, Henerton, near Henley-on-Thames. The heads were stated to measure from 20 to 30 inches in diameter. We are informed that some of the "combs" exceed the last-mentioned size, the largest of them being 31½ inches across. This is the largest size which we remember to have seen recorded. The colour of these heads we are also informed is extremely rich.

— A GARDENER, writing from Lincolnshire, states that amongst a large number of varieties of Potatoes which he has had growing side by side, the AMERICAN BREADFRUIT has proved the best both in respect of cropping and quality. The Rector of Woodstock is also found to be exceedingly good; but the palm of supremacy is awarded to Breadfruit. American Potatoes are unusually good this year, the hot season having suited them. An exceptional season and a specially favoured garden are not sufficient to test the merits of a Potato; a variety to be of real worth must be good over an average of seasons and in soils of various characters. We have known Early Rose, for instance, to be of splendid quality, while produce from the same stock of seed and growing in a different soil has been quite uneatable. It will be well if the American varieties are becoming acclimatised to England, for there is no question as to the superior cropping qualities of some of them, and of the handsome appearance of their tubers.

— A CALIFORNIAN botanist has sent to the *Rural Press* an account of the results of a careful measurement of the famous BIG TREES OF CALIFORNIA. The "Father of the Forest" has been said to have sprung from the earth soon after the Deluge, but the rings in his shattered trunk show that his full age at base is probably 1500 years. His alleged 40 feet diameter proves to be only 18 feet, measured at 6 feet from the roots. This correspondent adds—"One oft-repeated story is true, however, that of a passage through a part of his body large enough to admit horsemen. This passage, burnt out of his heart, commences at a point 66 feet from the roots, and extends 120 feet, coming out where was once a knot-hole, now enlarged by relic-seekers to a wide doorway. I saw several ladies ride horses of medium size through this wooden tunnel, and one day while passing, riding one of my horses and leading the other packed with bulky specimens, I turned into the cavity and rode safely through. The ceiling overhead is 4 feet to 6 feet thick, so the grand promenade for visitors above is perfectly safe." He mentions another monster tree, the stump of which he measured with his tape-line, "held at the other end by a Puritan master builder from Boston," and the longest diameter, including bark, at 5 feet from the base, was found to exceed 27 feet. He says also:—"The South Park Grove contains about five hundred trees, some of them of the largest class. One, the home of 'Trapper Smith,' is a vast swollen trunk at the base, 90 feet in circuit and 30 feet in diameter. The 'Livery Stable,' which has received twenty-two horses at a time into its hollow base, is 84 feet in circuit. A fallen tree is 15 feet in diameter 20 feet from the roots. A cavity is burnt in it sufficient to comfortably shelter twenty-five or thirty horses, or to afford the passage of a Concord coach and its four-horse team for over 200 feet. These dimensions do not materially differ from some published statements, but counts and estimates of the rings reveal only 1200 to 1500 in number. Other groves visited afforded corroborative evidence that, though the dimensions, being easily determined, are often given accurately, the age has been generally grossly exaggerated."

— TO CRYSTALLISE GRASSES.—The long feathery Grasses are best for this purpose. They must be thoroughly dry, formed in the desired shape, and fastened securely before being put in the bath. To make the solution, take 1 lb. of the best alum, pound it quite fine, and dissolve it in a quart of clear water over a slow fire, but do not let it boil. Take a deep jar and suspend the bouquet in it by a string from a stick laid across the jar. When the solution is milkwarm pour it over the Grasses, cover it up, and set it away for twenty-four hours. Then take them out carefully, and let them hang several hours in the sun till all the water is drained away. Then set them away, and do not move them for two or three days, when they will be entirely dry. If dried rapidly near the fire they will look as if powdered with snow. For blue crystals use a saturated solution of sulphate of copper in

hot water. For yellow use the yellow prussiate of potash; for ruby use the red prussiate of potash. These crystallised bouquets should be kept under glass shades or their beauty will soon fade.

— THE importance of planting TIMBER TREES has recently engaged public attention, not only in England, but in America, and for the encouragement of tree planting in Canada the *Toronto Globe* says—"The importance of replacing by fresh efforts extinct forests, or those which are in process of gradual removal, is receiving official consideration. The act of the Dominion parliament passed last session grants an additional quarter section, on payment of a trifling fee, to every settler on Dominion lands who plants thirty-two acres in successive annual instalments." In England also the systematic planting and intelligent management of plantations would be of great public benefit.

## ORNAMENTAL AND USEFUL TREE-PLANTING.

No. 6.

FOR ornament and eye-service we cannot overlook the Cyresses, Thujas, and Junipers, though British experience of them as timber is absolutely nil. The traditions of the growth, durability, and soundness of the upright Cypress (*Cupressus sempervirens*) in its southern home are founded on its having had a soil and climate less humid and drier than our own, where after three centuries of acclimatisation it does not reach half the height it attains in Italy, and is still chiefly valued as a fastigate tree, of kindred merits with the Lombardy Poplar. Hardier and kinder with us is the glaucous *C. Lawsoniana*, a hardy, rapid, graceful grower, which deserves Mongredien's praise, as "one of the most beautiful trees of a beautiful tribe." Its burden of pea-sized cones, which have a glaucous bloom when young, enhances the beauty of its foliage and graceful aspiring habit, in which last feature it differs from a somewhat earlier importation from the same country (California)—viz., *C. macrocarpa*, which is rather horizontal than vertical, and is apt to suffer from the lodgment of snow on its brittle rival leaders. Still *C. macrocarpa* is worth a place for its grass-green foliage, in which, as in other points, it is a greater contrast to Lawson's Cypress than the hardy Cypress from Nootka Sound. (*C. macrocarpa* was introduced in 1847, Nutskaensis in 1850, and *Lawsoniana* in 1852. —Mongredien, pp. 79–81.) Of the Thujas, all of which are hardy North Americans, the most graceful, compact and well-clothed is *T. Menziesii* or *Lobbii*, though *Thuja gigantea* is very distinct in its flat glossy branchlets. Our last special word must be devoted to the Sequoias or Redwoods, in which genus the *S. sempervirens*, a feathery, airy, and Fir-like Californian giant, introduced to this country in 1843, deserves more notice than the prominence and pretensions of its sister *S. gigantea* (more familiarly known as the Wellingtonia) allow it to enjoy. Its rapid growth (in its own country to the height of 300 feet) is often with us retarded by the loss of its leading shoots, but in a sheltered yet airy site, with a deep and porous soil of average quality, it should prove a valuable pyramidal tree. The specimen of it at Kew is a little over 40 feet; but at Whitfield Park, in Herefordshire, a group planted in 1851 were 45 feet high in 1868, at which time they were growing at least 3 feet in a year. Of shining dark green foliage and red-barked, their aspect is very striking, and their growth in moderate shelter is far more rapid than that of the Wellingtonia or the Larch. The frosts and the west winds are the Sequoia's chief peril. But the Sequoia sempervirens cannot expect to hold its own in comparison with a tree of which the traveller says that "if it were set by itself in a plain it would show like the Eddystone lighthouse." The so-called Wellingtonia, or Mammoth Tree as the Americans have dubbed it, was discovered in 1850 in the grove of Calaveras in Upper California; since which it has been found in seven or eight other groups in the groves of the Sierra Nevada. In one of these, the Mariposa group, many trees are 90 feet in girth and 300 feet in height; whilst a broken specimen in the Calaveras Grove (18 feet in diameter at the point of fracture, 300 feet from the ground), is calculated to have stood 450 feet high in its full growth. By counting the concentric rings it is reckoned to be 1100 years old: and it may be that our remote descendants may see veritable Mammoth Trees of marvellous age and stature in this country to which it was introduced by Mr. W. Lobb in 1852, and in which it is quite hardy, though a little apt to get its glaucous-green foliage embrowned by severe winters. By common consent no English park or pleasure of any size allows itself to be

without it; and we learn from the "Heatherside Manual" that there is an avenue of Wellingtonias upwards of a mile in length, with each tree healthy and vigorous, at the Company's nurseries at Bagshot.

The voids best filled with what Mason in his "English Garden" (ii., 175) designates as "all the stately progeny of Pines," the soils and situations they affect, and other such-like information, an amateur planter must, after all, ascertain in those visits to his sylvan nurseries which, if he be in earnest, will be no more intermittent than a tender parent's interest in his living offspring. One thing is certain, he must not "coddle" them. Books and practice alike enforce that Conifers only need to be high and dry in a pure air, and being anything but gross feeders, enjoy their natural health without asking for a rich soil. But it is interesting, in connection with this, to note the facts relative to the causes of Dropmore's success as a home of Conifers, and to see how far elsewhere kindred causes are leading to like results. The natural soil at Dropmore was poor and barren, at all events in that portion of the demesne with which we are concerned. It owes its transformation and wonderful tree-growths to the care of one man, its "genius loci" in the best of senses, Mr. Frost. From the time, half a century ago, when he received commission from Lord Grenville to "make his desert smile," he has never failed to bestow special pains on preparing stations for the Conifers before planting, and, after they have been planted, on maintaining a system of surface-dressing every autumn. However liberal the additional food annually bestowed, it is found "that the plants root right into it," and so teach a lesson to planters generally of the practical utilisation of road-scrappings, which make a capital surface-dressing, and which, nevertheless, the road surveyors not seldom find it hard to get carted from the roadsides. No one who has visited Dropmore under good Mr. Frost's intelligent escort can miss the clue to successful Conifer-growing contained in his two precautions; and we seem to see in the instance of Mr. Bassett's Pinetum and Plantations, a mile to the north of Leighton Buzzard, Beds, a similar though not identical process in the utilisation of waste and sandy ground. The subsoil there is, no doubt, richer; but the surface soil is a thin mixture of sand and vegetable matter, which has to be trenched two spits deep. The mode of planting specimen Conifers here is quite novel, and as follows: "When it is determined where a permanent specimen is to be placed, the ordinary trees of the plantation are cleared away, the ground is trenched 20 inches deep, and formed into an elevated circular platform 1 foot higher than the surrounding surface, with a slight rim, a little elevated to prevent the rain which falls on the surface from running off, and in diameter according to the vigour or nature of the ground to be planted. A platform 6 feet across is sufficient at first for the moderate-growing kinds; but for the more vigorous and robust-growing kinds a table of 10 feet is requisite, leaving the trench open round the outside to receive the fallen leaves; afterwards, as the roots are found to reach the outside, which generally takes place in from two to three years, another addition is made of from 3 to 4 feet all round." If in this case the *modus operandi* is different to that at Dropmore, it is because at the latter the subsoil is less available; the trenching, the elevation, and the addition to the platform from time to time, are seemingly applications of one and the same principle.

It remains to be considered, as a practical conclusion of the above survey of our arboricultural taste and triumphs, whether more might not be done, both publicly and privately, to extend, popularise, and turn to wider national account so valuable a possession. If, as was said in the outset, trees are a special passion with Englishmen, the future of our woodlands and forests demands that an interest in their culture and conservation should be spread far and wide among our countrymen, and rise superior to utilitarian calculations or the selfish pleadings of private interest. To such an end nothing could be more conducive than the opening of private and public parks, pineta, and ornamental plantations, to the view of the working class, under proper limits and restrictions, and a collateral resort to lectures by competent persons on the subject of their contents and products. As education becomes more widely diffused, it is not unreasonable to hope that the number of artisans and labourers will increase who will feel a quickened interest in the varieties and distinctions of deciduous and evergreen trees, which many of them already know in part; and such an interest would be cheaply fostered were every proprietor of rare and diverse tree collections to have his specimens legibly labelled, as is done so well at Victoria Park,

Bath, and in other public parks we need not mention. A diffusion of knowledge of trees and shrubs so simply facilitated might not only substitute an intelligent recreation for the grovelling pastimes which disgrace too many of our operatives, but might also lead, in their measure and within their means, to the embellishment and more cherishing of their homes. It would have the advantage of enlisting conservators for the arboreta and pineta of their betters; and the problem would not be so hard of solution, how far it is safe to remove the railings and fences of urban parks and gardens. The greatest possible credit is due to the proprietor of the Plantation near Leighton Buzzard, above referred to, for having had sufficient confidence in the wayfaring public to plant that part of his estate through which the high-road runs, for a considerable distance, with corresponding pairs on either side of *Picea nobilis*, *grandis*, *amabilis*, *magnifica*, *Lowiana*, *Nordmanniana*, and *Pinsapo*, as well as of the *Wellingtonia* and *Thuja gigantea*. This is one of the class of cases in which familiarity is not likely to breed contempt, but will rather school the eye, as it scans the turf lawn, to

"Expect that harmony of light and shade  
Which foliage only gives;"

and towards the fall to hail

"A canvas, which when touched by Autumn's hand  
Shall gleam with dusky gold or russet rays."

And so might a more compact phalanx be organised to preserve the rights immemorial, which the Englishman inherits, to the New Forest, and Epping, and Dean, and the rest. "We talk," says Mr. Wyse, in his charming history of the first of these, "about the duty of reclaiming waste lands, and making corn spring up where none before grew. But it is often as much a duty to leave them alone. Land has higher and nobler offices to perform than to support houses or grow corn; to nourish not so much the body as the mind of man; to gladden the eye with its loveliness, and to brace his soul with that strength which is alone to be gained in the solitude of the moors and the woods."—(*The New Forest; its History and its Scenery*, page 48). Another result might possibly be one which would recommend itself to the advocates of retrenchment. Were a popular wind to set strong and steadfast in the direction of practical and profitable arboriculture, there would be no reason why, as now, we should have to send our candidates for appointments in the Indian Forests department to perfect their arboricultural education in Germany at the cost of ratepayers whose boast it is to have so many royal forests and national woodlands, not likely, it would seem from recent decisions, to run further risk of being disafforested and turned to private and selfish use. In France some progress has, we believe, already been made in establishing a college of arboriculture and forestry, at the instance of M. Baltet, the clever author of a volume on "Grafting and Budding." The school of Nancy, and that at Tharand in Germany, might at any rate provoke this country to a peaceful rivalry. Had we space we might notice how ably this project has been broached in the second chapter of the "Forester," a work to which, along with those of Grigor, Prideaux Selby, and Mongredien, we have been greatly indebted in the foregoing remarks. But in earnest matter-of-fact England a hobby retains its favour and prestige all the more permanently if it combines advantage and utility with more æsthetic and sensuous attractions. We have endeavoured to show how far this combination has been achieved, and how much farther it may yet be achieved, in the extension of the sciences of arboriculture; and the labour will not have been vain if it help in anywise to stimulate a redoubled zeal in planters, great and small, public and private, and such a fashion for planting both deciduous and coniferous trees as may wax stronger and more deeply-rooted continually,

"till Albion smile  
One ample theatre of sylvan grace."

—(*Quarterly Review*.)

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

We have found it necessary to keep the hoe at work amongst the young Strawberry plants. Owing to continual showers weeds on freshly dug ground are very difficult to destroy, and running the hoe through them seems only to transplant them from one place to another. When the weeds are numerous and large it is better to rake them off and burn them, and then run the hoe through the ground a few days after. All freshly dug

ground should be hoed as soon as weeds appear, whether the ground is planted or not.

Those intending to plant young trees this season should have the ground prepared at once if it is not already done. The principal operation is the trenching of the soil; it is quite necessary that this should be done, and if the ground is poor some decayed stable manure should be added. If the soil will allow of it, it ought to be trenched to the depth of 2 feet, and the manure ought to be well incorporated with it.

We are now gathering the principal crop of Apples and Pears. A much larger proportion of Apples are attacked by the boring maggot than usual. This in conjunction with the scant crop causes us to be very careful of those fruits that are sound. The fruit is gathered very carefully and placed in baskets, whence it is conveyed at once to the fruit-room and laid-out on the shelves carefully by hand. We have gathered so far of Apples—Kerry Pippin, Ribston Pippin, Orange Pippin, Hawthornden, Pomona, Emperor Alexander, and, of course, all the earlier varieties. Of Pears—Fondante d'Automne and Louise Bonne of Jersey have been gathered. Williams' Bon Chrétien and Beurré d'Amanlis are now in use. Madame Treve is also very nearly ripe.

Intending planters should note the following Apples as being adapted for small gardens—Betty Geeson, Braddick's Nonpareil, Cellini, Court-Pendu-Plat, Cox's Orange Pippin, Cox's Pomona, Early Harvest, Emperor Alexander, Golden Reinette, Golden Pippin, Hawthornden, Irish Peach, Kerry Pippin, Keswick Codlin, Lodgemore Nonpareil, Mannington's Pearmain, Norfolk Bearer, Scarlet Nonpareil, Sturmer Pippin. Of Pears—Bergamotte Esperen, Beurré d'Amanlis, Beurré d'Aremberg, Summer Beurré d'Aremberg, Beurré Bachelier, Beurré Giffard, Beurré Hardy, Beurré Superfin, Doyenné du Comice, Durondeau, Fondante d'Automne, Glou Morceau, Jargonelle, Joséphine de Malines, Louise Bonne of Jersey, Madame Treve, Maréchal de Cour, Marie Louise, Seckle, Souvenir du Congrès, Summer Doyenné, Williams' Bon Chrétien, Winter Nellis, and Zéphirin Grégoire. It is now time to select fruit trees for planting. The best way is to go to the nursery and have them marked and sent when they are ready. If it is not possible to do this the order should be sent in good time, the nurserymen make it a rule to pick out the best trees first.

#### MUSHROOM HOUSE.

If the material has not been prepared no time ought to be lost in doing so. Stable manure is usually the staple material for making the beds; but if this is not plentiful, and cow manure can be obtained, two parts of stable to one of cow manure is well adapted for the purpose. One objection to cow manure is the difficulty of getting the material sufficiently dry. The best way is to throw it together in a ridge in a dry airy shed, or it may be spread out at a uniform thickness of 10 inches or a foot; this prevents it from becoming overheated, and the manure will dry quicker this way than any other. It ought to be turned over loosely every day. When pretty well dried the whole may be thrown up into a ridge to pass off the rank steam and heat. A little very dry turfy loam mixed with it will be an advantage, as it reduces the heat and moisture. The Mushroom house ought to be thoroughly cleaned out now to eradicate all insect pests. The old manure of the beds is useful in every garden, being available for potting purposes; and it is also valuable for mulching tender plants through the winter; it is further excellent for placing over the surface of Strawberry beds or fruit borders of any description. After all the manure has been removed from the beds the walls should be syringed and watered with boiling water. Woodlice and all other pests will be dislodged with this treatment.

#### VINERIES.

The Vines in the early houses have been pruned, and we are busy preparing for forcing. Perfect cleanliness is absolutely necessary to destroy the red spiders that hibernate under the loose bark. To banish the red spider all the loose bark is removed, the rods are then washed clean with a sponge and soapy water, and before they become dry they are painted over with the usual mixture; the principal part of it is flowers of sulphur. This should be mixed with soapy water to form a thin paste; a little soot and tobacco water should be added to it. This ought to be applied to the rods with a stiffish brush, working it well into the cracks. We also remove the surface soil from the inside borders to the depth of 2 or 3 inches, and replace it with fresh loam and rich manure. The walls are washed with lime water, and the rafters, sashbars, and glass are also made clean. It adds greatly to the clean appearance of the house to paint the hot-water pipes at this time. This ought to be done with lampblack and boiled oil when they are hot. The points of the Vines should be bent down to ensure their breaking regularly when they start into growth. The earlier the Vines are started, so much more is the chance of their breaking irregularly.

At this season there is much danger of the berries decaying in late vineries where the bunches have not been well thinned. When it is intended the Grapes should hang until the new year, the berries ought to be well thinned out. Any crowding, so that

the berries press firmly against each other, is a great mistake. One berry that has begun to decay, if it is not removed at once, will speedily destroy a whole bunch. No damp should be allowed in the house where the Grapes are. If it is necessary to fill the house with plants, then it is impossible to do the Grapes justice. We have found it necessary in both houses to apply artificial heat to ripen the Grapes.

#### PEACH HOUSE.

The trees in both early and late houses are now at rest, and the ventilators are open night and day. As soon as the leaves are removed from the early house what little pruning is needed should be done forthwith. There is generally some of the young wood that has grown too strongly; this ought to be removed, as it is seldom furnished with fruit buds, nor does it produce fruitful wood next season. Moderately strong young wood is the best. The inexperienced must be cautioned not to shorten the young wood unless it is possible to cut back to a triple bud. When three buds are together the centre bud is invariably a wood bud. If the summer treatment has been followed out according to previous instructions there will not be much pruning required.

Peach trees under glass are not unfrequently infested with brown scale, and this can only be effectually removed by hand-washing with soapy water. After having done this the trees may be washed with a similar mixture to that recommended for Vines, but it ought not to be quite so strong in soft soap and tobacco water. A mixture that would cause the blossom buds on Peach trees to drop would not in the least injure Vines.

The borders must not be allowed to become dry—that is, so dry that the fibrous roots are injured. If this happens the blossom buds might drop off in a mysterious manner, or blossoms would fall instead of setting.

#### FLOWER GARDEN.

We have been busy during the past week in this department, and there is plenty to do in the week to come. Cuttings of zonal Pelargoniums that were put in some few weeks ago have rooted very well on a sunny border. Now we are putting in cuttings of Verbenas, Ageratums, Heliotropes, and, in fact, every tender plant that is increased by cuttings, except Calceolarias, and a month hence will be sufficiently early to put them in. We have placed the boxes and pots containing the cuttings in a frame where there is a very little bottom heat. The frame is kept rather close and is shaded from bright sun. We have also taken up and potted all the plants we require of the tricolor Pelargoniums; all the older leaves were removed and the soil shaken from the roots so that the plants might be placed in small pots.

We have prepared ground by trenching it for Pinks and Tulips. We trench it 2 feet deep, placing a good layer of manure at the bottom of the trench, and another from 6 to 9 inches below the surface of the ground. The Pinks will be planted out at once. We have been potting-off Carnations and Picotees. They might have been done a week or two earlier, but experience has shown us that it is not desirable to pot them before the end of September, as the losses are greater when potting is done so early. The strongest plants are potted two in a 48-sized pot, and the smaller in large and small 60's. The compost used is two parts turfy loam, one of leaf soil, and one of sand. The pots are plunged in cocoa-nut fibre refuse, placed in a frame, and kept close for a few days.

Auriculas in frames have been looked over, the decayed leaves picked off, and the plants cleared from green fly with a small camel's-hair brush. The bedding plants have made a second growth after the drought; and as Hybrid Perpetual Roses are making the autumn bloom, with a little attention the garden may be made very enjoyable if the weather continues fine.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

H. Merryweather, Southwell, Notts.—*Catalogue of Roses*.  
T. Bunyard & Sons, Maidstone.—*Catalogue of Dutch Bulbs*, also *Descriptive Catalogue of Fruit Trees*.  
Thos. S. Ware, Hale Farm Nurseries, Tottenham.—*A B C Bulb Guide*, and *List of Hardy Perennials*.  
E. G. Henderson & Sons, Pine Apple Nurseries, Maida Vale, London.—*Catalogue of Dutch Bulbs*, also *Catalogue of Roses, Fruit Trees, Shrubs, and Climbers*.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

ABERDEEN. September 22nd and 23rd. Sec., A. J. Rennie, 123½, Union Street, Aberdeen.  
ALEXANDRA PALACE (Potatoes). September 28th and 29th. Mr. John McKenzie, 1 and 2, Great Winchester Street Buildings, London, E.C.  
NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.  
LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

NAMES OF FRUITS.—Our best authority for naming fruits is absent and will not be back for some time, so applicants must be patient.

HOLLYHOCK LEAVES SPOTTED (*J. H. C.*).—The spots are a fungus, *Puccinia malvacearum*. A drawing and full account of it is our No. 687, published May 28th, 1874.

MOSSY BALLS ON BRIAR (*Mary Rochfort*).—They are called Bedeguars, and are caused by a gall-forming insect called *Cynips Bedegaris*. It deposits its eggs in a bud of the young shoots of the Dog Rose and Sweet Briar. The grubs or larvae hatched from these eggs produce those galls or lumps covered with green and reddish fibres looking like moss so frequently found upon those shrubs.

IXIAS (*G. G.*).—Your specimen is *Ixia capillaris incarnata*. As you say it produces seed, and seedlings from them self-sown in your greenhouse, we think they ought to be raised more commonly in that way.

IVY FOR BORDERS (*R. D. G.*).—For covering quickly large surfaces the common Ivy—*Hedera Helix*—is the best. A quick-growing variety with mottled foliage is *H. canariensis maculata*. Some of the small-leaved variegated sorts are very ornamental, but are of slower growth than the above. The best way of obtaining a stock is to insert cuttings in a north border at the present time, planting them out where they are required after they are rooted.

CONSTRUCTING A CUCUMBER HOUSE (*A Market Gardener*).—The most suitable width would be 15 feet inside, which would give you a 4-foot border on each side of the house, with a 3-foot pathway up the centre. The flue should pass beneath each border in a chamber, which should be the width of the border, and be clear of the ground and of the flags or slates forming the bottom of the border, having shutters in the sides of the chamber next the wall about 3 feet apart to let out any excess of heat, returning the flues along the sides of the house to the end from whence they started, and having the chimney at the furnace end. The sides of the side flues may form one side of the bed, the top of the flue being level with the top of the border, and at every 3 feet upon the cover of the flue should be dishes formed of cement to hold water not less than an inch deep and 15 inches long, and as wide as the flue allows. The flues should be three bricks (set on edge) deep, and 9 inches wide inside, and the length of the house should not exceed 36 feet. The border should be 18 inches deep, 6 inches for drainage, and a foot for soil. The side walls of the house should be the height of the border, and the side lights need not be more than 18 inches in height. The trellis should be 14 to 15 inches from the glass, and the wires 6 inches apart. You may have the sides wholly of brickwork, and introduce wooden ventilators at 3 feet apart, the ventilators being 18 inches by 1 foot, opening on a pivot. You will need ventilation at the ridge, a light not less than 18 inches wide made to open the whole length of the house, regulating it at will. A square cistern at each end over the flue is good, it will give you tepid water for watering with; but we think that with your two flues and consequently two furnaces, you will expend more fuel the first year than would clear the additional expense of heating with hot-water pipes, one fire and boiler being sufficient for your purpose, besides much more satisfactory.

CYCLOAMEN ROOTS GRUB-EATEN (*A Reader of the Journal*).—Your only remedy will be to turn all the plants out of the pots and examine the corms, to do which it will be necessary to remove the soil and repot in fresh compost. We do not know of any remedy other than searching for and destroying the grubs. By frequently turning the compost in a heap and sprinkling the layers in turning with soot the grubs may be driven from the soil.

PRUNING ZONAL PELARGONIUMS (*C. R.*).—They should not now be cut back, but any straggling growths may be shortened, deferring the general pruning until February or early in March. Repot them after they have made shoots an inch long, removing most of the soil from amongst the roots, returning to pots just enough to hold the roots, and when they have made fresh roots and before they are much matted shift into the blooming pots. Mrs. Pollock and other variegated Pelargoniums should not be cut back until spring, and after they have made fresh shoots should be repotted.

CUTTING DOWN BROOM (*Idem*).—It is desirable to cut down old straggling plants, but if very old they do not start away freely. The best time to cut them down is early in March.

PRUNING OLEANDERS (*Oleander*).—They, if ill shaped and straggling, may be cut down in April, but they will not flower the same season, nor would they flower next year were you to cut them down now. Defer heading them back until early in April, when they will produce flowering shoots for the following season.

CULTURE OF BRUNSVIGIA JOSEPHINE (*Lovestoft*).—It requires a light airy position in the greenhouse, and to have a pot twice the diameter that of the bulb, using a compost of fibrous yellow loam with a third of leaf soil or a fourth of old cow dung. As your bulb has not begun to grow we should keep it just moist over the winter, and in February or early in March plunge the pot in a hotbed and continue there until fresh growth is made. After it is somewhat advanced gradually withdraw from the hotbed and remove to the greenhouse, keeping well supplied with water until the growth ceases, and then only afford water to keep the foliage from flagging.

EXHIBITING VEGETABLES (*J. R. Alloties*).—There is no book giving special instructions. Grow the vegetables as well as you can, and exhibit them according to the conditions stated in the schedule.

RIPENING MELONS (*M. E. N.*).—When the fruit commences ripening water should be withheld altogether, as a moist soil and atmosphere causes the fruit to crack, and is inimical to its flavour. We cease watering totally after the first indication of ripening, or a week to ten days before the fruit is ripe,

though when a second crop is to be taken the plants are not allowed to suffer for moisture at the roots, but in that case even the moisture is not nearly one-half so much when ripening as during growth. After a Melon is full-sized and netted completely moderate moisture only is required, and the less the plants have after the ripening colour is assumed the more concentrated are the juices—the higher the flavour.

DUNDEE INTERNATIONAL EXHIBITION.—Messrs. John Stewart & Sons, The Nurseries, Bronghty Ferry, inform us that our reporter omitted to state that they had first prize for six Conifers, one plant of which, a *Cupressus Lawsoniana lutea*, was said to be the best plant of it in the kingdom; first prize for a Tree Fern, first for *Todea superba*, first for *Fern* case filled, first for hand bouquet, first for fancy Dahlias, first for Hollyhocks, and second for four other entries.

COLD ENDURED BY COLEUSES (*T. Harlam*).—You should have stated the name of the species. None of the tender sorts should be exposed to a lower temperature than 45°.

SULPHATE OF AMMONIA (*Chesterfield*).—It remains in solution after adding the sulphuric acid to the urins. We cannot name Ferns that have no spores.

RHODODENDRON BED FOR ROSES (*Tyro*).—Mix the soil thoroughly with that of the surrounding border, adding some thorough decayed stable manure, and keep the surface over the roots of the Roses well mulched.

GROWING MELONS IN STRAWBERRY PIT (*A Constant Reader*).—The pit will, we presume, be at liberty after May, and would after that be available for growing Melons, the plants having been raised by sowing the seed in a hotbed a month previous to planting in the house, being then strong plants. They succeed well in pots—11 or 12-inch pots being suitable, but we prefer them 14 inches in diameter, as the necessity for high feeding is not so much needed as in the case of smaller pots.

CACTUSES, HOYA CARNOSA, AND BEGONIAS (*Nemo*).—Cactuses flower in April or May in a greenhouse, and *Hoya carnosa* in June onwards in a greenhouse; but in a stove it flowers from April to November, the flowers being most numerous in May and June. Begonias of the flowering greenhouse section should be kept rather dry now, and drier as colder weather approaches, and dry during winter, but not dust dry, and in March should be repotted, removing most of the old soil, placing them in smaller or the same size of pot. Water should be moderately given until growth takes place, increasing it with the growth, watering freely when the growth is vigorous, and shifting into larger pots, avoiding making the soil sodden by too frequent waterings. Afford a light position when growing, and safety from frost when at rest.

RIPENING PEACHES, NECTARINES, AND PLUMS (*Y.*).—Any leaves overhanging the Peaches and Nectarines should be cut so as to expose the fruit to the light, that being necessary for colour, and, as some think, flavour. High colour and flavour usually go together, but we have had Peaches quite as high-flavoured upon the under side of the trellis shaded by the leaves as upon the upper side and exposed to the sun. Inequality in colour is very objectionable, for when a leaf covers one-half the fruit, the other being exposed, the exposed part will be very deeply coloured, while that part covered by the leaf will be very deficient in colour, and the exact outline of the obstruction may be impressed upon the fruit. Expose the fruit, but do not remove the leaves, only those parts of them covering the fruit. Plums, if summer pruning has been properly attended to, ought not to have any foliage removed in order to expose the fruit to light.

CUCUMBERS GUMMED (*W.*).—The exudation or gangrene arises from a too rich and moist soil, and too moist and cold an atmosphere. Afford a brisker heat with freer ventilation, and soil less rich and moist. The disease is very common, especially in dung-heated frames in late summer.

PREPARING TOBACCO FOR FUMIGATING (*Constant Reader*).—We take the following from the "Gardeners' Year-Book":—"When the leaves have attained their full size and become of a yellow hue they are taken from the stalk, tied together in small bunches by the footstalks, hung in a dry airy room, and left there until dry and crisp. The first damp weather after this the leaves will become soft, and they should be watched to ascertain when this occurs; then pack them in a box evenly, with the butts or stalk ends of the leaves all one way. They are then to be pressed moderately, and in a few days a slight fermentation will take place, when the bunches should be taken out and shaken to let the heat escape. When this has been done repack lightly. The leaves will not re-heat, but it is best to let them remain for a few days laid lightly in the box, and when all fermentation is over pack tightly in a barrel, and keep in a dry place ready for use. As the leaves of British-grown Tobacco are not all mature at one time they must be successively gathered as they ripen."

PROTECTING GERANIUMS IN BEDS (*Wyld Savage*).—You may, perhaps, succeed in your mild climate if you cut the plants down after the first frost to about 6 inches from the ground, and remove all the leaves and weeds from the surface, and cover with ashes 6 inches deeper than the topmost shoots, and over this in very severe weather, if snow do not fall, should be given a covering of litter. The ashes may remain on until April, when they should in mild weather be removed, having at hand protective material as mats to throw over the bed in case of frost.

PLANTING TREES AND SHRUBS (*H. T.*).—Marshall's "Planting and Rural Ornament" would suit you. It was published by Messrs. Nicol, but we think can only be obtained from a second-hand bookseller.

GRAPES DISEASED (*Mrs. Cooper*).—They are shanked—that is, the stalks are dead from the want of sap. The roots are deficient in action, and they might be stimulated by removing the surface soil and watering them copiously with tepid weak manure water.

FERNS (*W. D., Guernsey*).—Only one specimen, and that not numbered, came.

NITRATE OF SODA (*C. P., Herts*).—It may be applied to your Vines and all garden crops at the rate of 1 lb. to 30 square yards, at any time whilst they are growing.

DESTROYING ANTS (*Inquirer*).—You might entice them to a saucer smeared with honey and destroy headatoms at once. Scotch snuff sprinkled on and around the flower bed would exclude them.

SEWAGE (*J. Thomas*).—Collect it in a cistern; you can then dilute and apply it where it is required. No spray of a Vine was in your letter.

HEATING BY A PARAFFIN LAMP (*N. G.*).—We do not see how you propose to heat the tank in your propagating frame by means of a paraffin lamp, as it will be necessary to dispense with a glass, and then you will have smoke which will need to be conveyed clear of the frame and greenhouse by a chimney. If you have no greater difficulty than regulating the heat, that you

may readily overcome by putting the wick higher or lower. It is likely to be very costly, as the consumption of oil is not likely to be less than 3d. per twenty-four hours. Those having experience in heating small frames by means of a lamp would oblige us by a statement of their experience.

STOVE HEATED BY PETROLEUM (N. C.).—We have no experience with such a stove. Any of our readers who have used one will oblige by sending us the information, maker's name, &c.

INSECT ON FERN (*Sussex*).—It is the thrips. Dust the fronds with Scotch snuff, or sponge them with soft soap and water. If the specimen you sent was without spores, the same as the present, no one could identify it.

NAMES OF PLANTS (C. B.).—We cannot name plants from such dried flowerless specimens. They should be sent in a box with dampened moss. (*Hampshire*).—Specimen insufficient. (*S. H.*).—A species of *Eucomis*, perhaps punctata. (*Constant Reader*).—1, *Lycocystis formosa*; 2, *Solidago*, probably canadensis. (*W. G. C.*).—A, *Nephrolepis cordifolia*; B, *Athyrium Filix-femina*, var. (*F. C. B.*).—1, *Cymbidium elegans*; 2, *C. giganteum*. (*F. B.*).—All forms of *Lastrea dilatata*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LES BASSES-COURS D'ANGLETERRE.

#### CHAPTER VIII.—THE CEDARS, BATH.

We had long promised to pay Mr. and Mrs. Holmes a visit, but somehow the spring melted into summer, and the summer into autumn, and we had never found the right day. A fortnight ago, however, we determined to throw aside all other engagements and kill two birds with one stone—see the poultry show in the Sidney Gardens and the aviary birds and poultry at The Cedars. Perhaps many will think we could not have chosen a worse day in the year, as Mr. and Mrs. Holmes had close on fourscore pens of birds away at the Show, but we can assure them we found plenty left to criticise, and we could only marvel where the eighty pens lived and lodged when they were at home, for every run and house seemed to have its full stock of inmates. Flower culture has been abandoned at The Cedars, not because the fowls were found to be bad gardeners, but because the trees form such deep masses of shade that flowers will not grow under them. So we found White Cochins hens walking up and down upon the grass, looking at their husbands, which were penned in small separate wire runs on one side of the lawn. These hens seemed very good, one especially took our fancy. They were own sisters to "Blunder," as Mrs. Holmes jocosely terms the beautiful pullet which was passed at the last Bristol Show for being too like a hen. White Cochins should be white at The Cedars, for they have a closely-cut lawn and luxuriant shade over it. The pens where the gentlemen were enclosed, on whom we found the ladies gazing, were planted with laurels and shrubby bushes, but they gave us the idea of being rather damp. They contained a good lot of birds, and though now in very ragged plumage, they have much breadth and thickness of build, so with care and judicious feeding they should make useful competitors for the winter Cochins prizes.

At the end of this lawn, which is on a sloping hill, we found an old summer-house, not one of those little arbours which we find in suburban gardens, useful only for harbouring flies and beetles and such-like odious insects, but a genuine summer-house, a house with rooms and fire-places, and stained glass windows. In one room we found Pigeons—capital Pouters, a good pair of Fans, a Black Tarbit or two, and some very fair Runts, for Mr. Holmes has been desperately bitten with the Pigeon fancy, and is getting up a goodly stud.

In another room we found birds, some of those little feathered wonders with which Mrs. Holmes is so successful. We would not pretend to give their names, for we confess we do not know them. We know we made out Love Birds, and Wydahs, and Bishops, and Pekin Nightingales, and many more. They live together as happy as possible, and seemed very tame. One snow-white Dove, which had eggs, would allow us to touch her and stroke her without ruffling a feather. The next room was the basket room, and was full of all sorts of odds and ends in the way of cages and baskets, and bottles and canisters, which are indispensable in a large poultry establishment. Underneath these rooms was the sitting apartment, and one or two obstinate old ladies were even then patiently trying to produce something from empty nests. Near here we found, too, a perfect drove of Light Brahma hens of all sorts and ages and sizes. We could easily spot one or two first-rate birds, but they were mostly very much out of feather, and it seemed unfair to criticise them.

Lower on down this sloping garden we found some Bantam houses, charming little tenements, with tiny enclosed runs. One was empty, for here live when at home the Black Booteds which won the Bantam cup at Weymouth the week before last, and which were on exhibition at the Bath Show with a prize card on their pen. These little houses were built on a plan of Mr. Holmes's own idea, and they seemed very good. They are built in pairs, with a little passage between each house, and have a dry run as well. The whole top lifts up in pieces for ventilation, on the same principle as the roof of a

greenhouse, so the houses are always weathertight, and can be made airy or close entirely at pleasure.

After we had done the garden part we passed through a gate in the garden wall into a sloping paddock, a good slice of which had been cut up into enclosed runs for the birds. The first thing, however, which caught our eye was a cock of peculiar colouring and shape, and we at once asked for its history. We were told it was several years old, and was a cross between a Duckwing Bantam and a Silky. We know we had seen a *fac-simile* somewhere, and then suddenly remembered it was in the "Illustrated Book of Poultry," by Mr. Lewis Wright. Had it not a tiny crest and a reddish-purple comb we are sure it must be the image of the cock in the illustration on page 296 of the above-named work, and there called "Ayam Jallak, a Malay Game cock, drawn from life by a native Chinese artist."

In the runs in this field we found White Cochins, Light Brahmas, White Japanese, Silkies, Indian Bantams, and Mottled booted Bantams. They were of all sizes and ages, and had to run in the very greenest grass runs without exception we ever saw. The Silkies were mostly wonderfully good, especially in crests and leg feathers; but we saw traces of vulture hocks in many birds, and consider them not only an eyesore but a disqualification. We noticed some very promising White Cochins and Light Brahma cockerels, but we thought the cream of the young stock was in a score of fully matured Light Brahma pullets. They were in a barn-like shed littered down with straw, and they appeared to be as good and as even a lot as well can be imagined. Good they were in combs, pencillings, feathering, and shape. We did not wonder at their quality, for we found their male parent in the next run, and a noble-looking bird he was, heavy, massive, and of upright carriage. He had a triangular run, and up in the top angle was his house; and the run being on a steep incline he had to approach his residence by steps. It seemed to have three storeys, and when we saw him first he was looking out of the window of the second floor contemplating the scene below. It was quite ludicrous to see him descend and walk down his flight of stone steps to the run below after some choice morsel. We saw here, too, a very tame common hen Pheasant, which walked about paying calls from run to run. Mrs. Holmes told us she had laid all through the summer with surprising regularity. We found also near here another house full of Pouters, and Runts for feeders; and the chicken nursery, which was a very low shed, apparently very warm, with a glazed front.

After we had exhausted the poultry runs there were long-haired cats to see, and a family of dogs, and many more rare foreign birds indoors. It was altogether a most enjoyable little visit, and we felt quite sorry to leave the stock here, even though it was to see the cream of the establishment in their pens in the Show, but we look forward to spending another long day at The Cedars, and are certain we shall find many treasures which had to be passed over unnoticed on this occasion. A glance at the prize list of the bird department of the Bath Exhibition will show the quality of Mrs. Holmes's stock, and we congratulate her warmly on her success, and hope Mr. Holmes (who, by-the-by, himself won the Pouter cup with a bird of his own breeding) will do as great things in his Pigeons, for no two kinder-hearted or more enthusiastic fanciers are to be found in our ranks.—W.

### MIDDLETON-IN-TEESDALE SHOW OF POULTRY, &c.

THIS Show was held at Middleton-in-Teesdale on the 15th inst., and for a first attempt in such an out-of-the-way place the result was excellent, and the capital way in which the Show was managed was such as to be well worthy of being copied by other societies. Everything being in readiness for judging at nine o'clock, ample time was given for the awards, and all was completed before the visitors were admitted. Mr. Gibson, the Secretary, not competing, placed some very good Aylesbury Ducks in the Show for inspection.

The open division in poultry was for all ages, but a great number were birds of this year. Brahmas were but a moderate class, and most of these of the Dark variety; but Cochins were much better, and the winners all Buffs, first and third old, and second young. Dorkings were a very good lot, and the cup for the section was given to the first pen. Leghorns had a class, but most of these were very shabby in feather, but otherwise good; Browns first, and Whites second. Spanish were good, the cup going to an adult pen. Polish also a good class, most of the winners Golden, with one pen of Blacks. Game, Reds were well represented, adult Brown Reds first, cup, and second, and Black Red chickens third. In single cocks the first was the Otley cup Duckwing, still looking well, and well worthy of his position. Hamburgs a good lot, and the cup given to a pen of Gold-spangles, the cock in prime order still, after a whole year's hard work. Bantams, Game, first-and-cup Black Red chickens, very smart and gamey; second barely losing, were also of that variety. In Any other variety first were Blacks, but the cockerel is too light on leg; Silver-laced were second,

and a pretty good pen. In the Variety class the first were Creves, second Black Hamburgs, and third Houdans. *Ducks* were very good in all classes; the cup was awarded to Rouens, which were an excellent class; and in the Variety class the awards were made to Carolinas, White-faced Whistlers, and Bahamas.

In *Pigeons* the mistake of exhibiting in pairs had been made, and though the entries were pretty good, yet it is certain this system worked considerably against great numbers. Pouters were first with ten pairs, but the pens were far too small, and the birds did not show well, and the rule had to be resorted to, and most of the birds were in very bad feather, though first were in fair order, a very good pair of Whites, and priced at only £4 10s. Carriers were very poor except the winners, which were good Blacks and Duns. Tumblers very good; first Almonds, second Kites, and third Agates. Owls a mixed class, the foreign Whites by far the best, the cup for the best pen in the Show going to the first-prize pen. Fantails a capital class, but sadly crowded in the pens. Barbs, the winners good Blacks, but the rest poor. Turbits, winners Blues, and good. In the Variety class several extras were given, the class being unusually good; first Trumpeters, second Yellow Magpies, extra second Trumpeters, third Blondinettes and also Trumpeters. In the Selling classes were some very good pairs, best among these being a pair of Ural Ice.

The local classes for poultry were but a testing point for the feelings of the inhabitants of the district, and with excellent results as regards numbers, though in most cases little can be said of the quality, although there was one very good pen of Silver Dorkings and one of Gold-pencil chickens; and the Duck and Geese classes were very good. A class for Parrots brought out the Sunderland wonder, which is certainly sufficient amusement for an hour to any who has not heard it before.

**POULTRY.**—BRAHMAS.—1, E. Pritchard. 3, Mrs. Ellison. 4, S. Lucas. COCHINS.—1 and 3, G. H. Procter. 2, C. Sedgwick. DORRINGS.—Cup and 1, J. T. Proud. 2, E. Snell. 3, T. P. Carver. 4, J. T. Proud. LEGHORNS.—1 and 3, E. Brown. 2, H. L. Bradwell. 4, J. M. D. Smith. SPANISH.—Cup, 1, and 3, R. Newbitt. 2 and 4, J. P. Fowler. POLDS.—1 and 3, A. & W. H. Silvester. 2, J. T. Proud. 3, J. Goodburn. GAME.—Black or Brown Reds.—1, E. Winwood. 2, J. Nelson. 3, C. Smith. 4, E. Snell. Any other variety.—1, J. A. & H. H. Staveley. 2, E. Winwood. Any variety.—Cock.—1, J. Nelson. 2, C. Smith. 3, J. Cook. 4, W. Youngusband. HAMBURGS.—Golden-pencilled.—1, J. Smith. 2, T. P. Carver. 3, W. Clayton. Silver-pencilled.—1 and 2, W. Jopling. 3, J. Stuard. 4, Holmes & Destner. Golden-spangled.—Cup and 1, E. P. Carver. 2, Holmes & Destner. 3, J. Jackson. Silver-spangled.—1, J. Stuard. 2, G. Alderson. 3, J. J. Walker. 4, Holmes & Destner. BANTAMS.—Game.—Cup, 1, and 4, G. Hall. 2 and 3, J. Nelson. Any variety.—1, C. & J. Illingworth. 2, T. P. Carver. 3, E. Snell. 4, E. Pritchard. ANY OTHER VARIETY.—1, W. Clementson. 2, C. Sedgwick. 3, Rev. J. G. Milner. 4, J. Mackwell. DUCKS.—Aylesbury.—1, J. Walker. 2 and 4, E. Snell. 3, F. Waller. Rouen.—Cup and 1, F. G. S. Rawson. 2, J. Walker. 3, Holmes & Destner. 4, H. B. Smith. Any other variety.—1, J. Johnson. 2, J. Walker. 3 and 4, A. & W. H. Silvester. SELLING CLASSES.—1 and 2, S. Lucas. 3 and 4, J. Brockwell. 5, A. & W. H. Silvester.

**LOCAL CLASSES.**—BRAHMAS.—1, F. W. Little. 2, J. Smith. 3, Rev. E. Good. DORRINGS.—1, P. Amos. Cup and 2, R. Hodgson. 3, K. Hutchinson. SPANISH.—1, I. Bradwell. 2, W. Scalfie. 3, Alinson & Bradwell. GAME.—1, J. Kipping. 2, J. Richardson. 3, W. Coates. HAMBURGS.—1, J. Alinson. 2, J. P. Dalton. 3, J. D. Breckinfield. BANTAMS.—1, R. Armstrong. 2, R. Coltmann. 3, J. **JUDGES.**—Mr. R. Teebay, Fulwood, Preston: Mr. E. Hutton, Pudsey, Leeds.

## WELLINGTON (SALOP) POULTRY SHOW.

The entries at this chicken Show were very good, and we think the Show would amply repay for better classification.

The *Game* made a good display, as they generally do in these parts; and *Game Bantams* won also in the Bantam class. In *Dorkings* a good pen of Silver chickens won first prize; the pullet was a very fine bird, but the cockerel rather too striped in hackles. Second went to a moderate pen of Coloured. *Brahmas* were a very fair class; the second cock was a good deal spotted upon the breast. *Cochins* were a moderate collection; Buff chickens were first, the cockerel rather pale; second went to Whites, good in colour and neat in appearance, but small, and the cockerel very lightly feathered; pen 57 (Darby) better in feather and colour, but still ill-shaped and unfurnished; 59 (Swindell) fair Buff chickens, the pullet, however, rather mottled

in colour. In *Hamburgs* a good pair of Gold Pencils won first, and Silver-spangles second. *Spanish* were not a grand lot, and of the two prize pens we liked the second best. In the Variety class first good Silver Polands; the second prize went to Redcaps, at least so the catalogue termed them; they were nearly black, with a few red patches here and there. 72 (Taylor) large well-grown Houdans; 77 (Fowler) empty; 74 (Brooke) good Malays. In the class for the heaviest couple a bad pair of Bufts first, and small and young Dark Brahmas were second. *Ducks* were a good lot considering that all breeds were classed together. Aylesburys won first, which were soon claimed at £3, and second also went to the same breed; 97 (Truelove) Rouens. *Geese* were also a very fine lot; Toulouse were first and second. Next came the classes for birds of any age. *Game* were a good lot, and excellent Brown Reds won first, and smart Black Reds second. In the next class Brahmas, Dorkings, and Cochins competed together. Most of the birds were much out of feather. Light Brahmas were first, the hen in this pen being good; second good White Cochins of large size. Mrs. H. Bailey showed a pen of old Silver-Grey Dorkings, but out of feather. In the *Waterfowl* class pretty Whistlers won first; 170 (Bailey) beautiful White Calls; 174 (Darby) very pretty wild Ducks. The *Turkeys* were few but good; while the adult *Geese* made a fine lot of a dozen pens. Altogether it was a very good little Show, and we were surprised to find so much quality for such poor and scanty classes. We give the list of prizes below:—

### CHICKENS.

**POULTRY.**—GAME.—Black or Brown Red.—1, G. F. Ward. 2, W. Dunning. Any other variety.—1, G. E. Meredith. 2, G. Barnesley. BANTAMS.—1, J. Mayo. 2, S. W. Smith. DORRINGS.—1, Countess of Dartmouth. 2, Rev. E. B. Charlton. BRAHMAS.—1, F. Bennett. 2, C. Naylor. COCHINS.—1, C. Sidgwick. 2, Countess of Dartmouth. HAMBURGS.—1, H. Feast. 2, T. W. Hallam. SPANISH.—Black.—1, J. Clews. 2, H. Blower. ANY OTHER VARIETY.—1, Countess of Dartmouth. 2, T. W. Jones. SELLING CLASS.—1, Mrs. E. Williams. 2, J. Aldred. HEAVIEST COUPLE OF FOWLS.—1, Miss A. Brooke. 2, T. W. Jones. DUCKS.—1, J. Hedges. 2, J. K. Fowler. GESE.—1, T. Mills. 2, E. Shaw.

### ANY AGE.

**POULTRY.**—GAME.—1, E. Winwood. 2, Mrs. H. J. Bailey. DORRINGS, BRAHMAS, OR COCHINS.—1, Countess of Dartmouth. 2, A. Darby. SPANISH OR HAMBURGS.—1, J. Carr. 2, F. Powell. SELLING CLASS.—1, S. W. Hallam. 2, Miss A. Brooke. DUCKS.—1, H. Yardley. 2, J. Hedges. GESE.—1, T. Mills. 2, T. Radcliff. TURKEYS.—1, W. H. P. Nock. 2, Countess of Dartmouth.

## BRACKLEY POULTRY SHOW.

The Northamptonshire Agricultural Society met this year at Brackley, and had a very pleasant meeting. The entries in the various poultry classes were not large, but the quality was mostly very good. *Dorkings* we were most especially sorry to find so meagre in numbers, for they are essentially farmyard fowls, and should always put in as large an appearance at an agricultural show as do sheep and pigs. A good cockerel won first in the Coloured class, and the first pullet in the next class was an equally promising bird. *Spanish* chickens were very good. The first pullet very neat in head. A very smart Brown Red pullet won in the *Game* pullet class for Reds. The other two *Game* classes were, however, so poor that only the first prize was awarded in the class for cockerels, and none in that for pullets. Buff *Cochins* were a fair lot. The first cockerel was well coloured, and looks as if he had much more growth in store. The pullets were well grown, but we have not seen this year any so very startling in colour as yet. In the next class all the cockerels were White, the first much earlier than the second, which was, however, a well-growing chicken. In pullets the first was larger than the second, but not quite so good in shape. In Dark *Brahma* pullets the first was fairly pencilled, but the Lights were by far the best, and the pullets were really exceedingly good. In *Hamburgs* a capital Silver-spangled won second in pullets; the third, too, was also a good Silver. In the Variety class four Black Hamburgs and two Brown Leghorns competed for the five prizes. A very good Black cockerel won in the first class, and a pretty Brown Leghorn third. In pullets the Leghorn came first and the Hamburg second. In *Bantams* good laced birds easily came first for the two first prizes. *Waterfowl* were very good. The Rouens really capital, a large pen of Duckwings winning first. In Aylesburys we thought the bills of a much better colour than we have seen of late at many shows. The Sale classes were large, and the second-prize pullets were not a dear pair.

*Pigeons* only had one class, and when a committee can only provide one class we think they would be better without any, for it only causes dissatisfaction, as no judge can be expected to please all in such a medley.

Mr. Hewitt awarded the prizes and gave satisfaction. We publish the list of prizes below.

**POULTRY.**—DORRINGS.—Silver-Grey or Coloured.—Cockerel.—1, R. Wood. 2, E. Snell. Pullet.—1, E. Snell. 2, J. Gee. Any variety.—Cockerel.—1, J. Gee. 2, E. Wood. 3, R. E. Oliver. Pullet.—1, R. E. Oliver. 2, R. Wood. SPANISH.—Cockerel.—1, Mrs. E. Allsopp. 2, J. T. Parker. 3, D. M. Mills. Pullet.—1, Mrs. E. Allsopp. 2 and 3, W. Notlage. GAME.—Black or Brown Red.—Cockerel.—1, E. Snell. 2, W. Roberts. 3, B. Cox. Pullet.—1, S. Tilley. 2, Mrs. Deacon. 3, E. Snell. Any other variety.—Cockerel.—1, Mrs. Deacon. COCHINS.—CHINA.—Cinnamon or Buff.—Cockerel.—1, C. Sidgwick. 2, W. A. Burrell. Pullet.—1, W. A. Burrell. 2, C. Sidgwick. 3, J. Gee. Any other variety.—Cockerel.—1, C. Sidgwick. 2, Rev. R. S. Woodgate. 3, E. Snell. Pullet.—1, E. Snell. 2, Rev. E. S. Woodgate. 3, C. Sidgwick. BRAHMA POOTRA.—Dark.—Pullet.—1, M. Leno. 2, C. F. Herrieff. 3, W. Roberts. Light.—Cockerel.—1, E. Snell. 2,

Mrs. Peet. 3, M. Leno. *Pullet*.—1, Mrs. Peet. 2, Mrs. S. Browne. 3, M. Leno. *HAMBERGES*.—*Gold and Silver-spangled*.—*Cockerel*.—1, W. Roberts. 2, J. Long. 3, J. Ward. *Pullet*.—1, W. Roberts. 2, J. Gee. 3, W. Pinfold. *Gold and Silver-pencilled*.—*Cockerel*.—1, J. Long. *Pullet*.—1, W. Roberts. 2, J. Long. *ANY OTHER DISTINCT BREED*.—*Cockerel*.—1, J. Long. 2, C. F. Herrieff. 3, C. Sidgwick. *Pullet*.—1, C. F. Herrieff. 2, C. Sidgwick. 3, J. Long. *BANTAMS*.—*Cockerel*.—1, M. Leno. 2, W. Ellis. 3, W. Nichols. *Pullet*.—1, M. Leno. 2, W. Ellis. 3, W. H. Nichols. *GEES*.—1, E. Snell. 2, J. L. Stratton. 3, Mrs. Deacon. *DUCKINGS*.—*Aylesbury*.—1, T. Kingsley. 2, E. Snell. 3, T. Holton. *Rouen*.—1, J. Gee. 2, E. Snell. 3, J. Long. *TURKEYS*.—*Young*.—1, E. H. Grimsdick. 2 and 3, W. Nichols. *SELLING CLASSES*.—*Cock or Cockerel*.—1, M. Leno. 2, F. Newbitt. 3, H. Yardley. *Hens or Pullets*.—1, T. Love. 2, H. Yardley. 3, Mrs. E. Allsop. *Drake, Gander, or Turkey Cock*.—1, E. H. Grimsdick. 2, T. Kingsley. 3, T. Holton. *Ducks, Geese, or Hen Turkeys*.—1, T. Kingsley. *PIGEONS*.—*ANY DISTINCT VARIETY*.—*Cock or Hen*.—1 and 4, H. Yardley. 2, W. Nottage. 3, T. W. Swallow.

### HONEY AND WAX.

The statement of Professor Riley touching the question of the production or manufacture of honey from the sweet nectar of flowers is, in my opinion, both interesting and important from a scientific point of view. The truth is so well told in his statement that I will venture to repeat it here. "Bees," he says, "do not extract honey ready-made from flowers, but make it. The nectar lying in flowers could never be manufactured into honey, no matter how manipulated by man, but is taken up by the bees and passed through a state of semi-digestion and excretion, resulting in honey, yet still retaining in part the flavour or perfume of the flowers from which the nectar has been extracted, by which we determine one kind of honey from another." Honey, then, is a secretion of bees to some extent as well as wax. This fact has been well known by most of the bee-keepers of Lanarkshire for sixty years. It was one of my first lessons, well learned before I could master the multiplication table, and ever since when I have been able to turn up a hive and examine its combs convincing evidence in multiplied form has been before me that the crude honey found in flowers and gathered by bees is afterwards changed and converted into honey proper. After having been gathered and disgorged it is re-swallowed, and then passes through a process of preservation, in which it is thickened and sweetened, "resulting in honey," as the professor puts it.

How much, then, is man indebted to the honey bee! What a life of toil and industry do we witness in a hive of bees! Where else can we find such lessons of cleanliness and comfort, of freedom and fraternity—of an industry that is as active at home as it is abroad, as active by night as it is by day—an industry that knows nothing of peevishness or fretfulness? There is a world of wonders in a bee hive which the most observant sages of mankind will never compass or fathom.

Wax is more distinctly a secretion or product of bees, inasmuch as it is very unlike the honey from which it is secreted or manufactured. The manufacture of wax by bees is a marvel from the beginning to the end. The process is hidden, and is likely to remain a secret. The results are evident. Bees can secrete wax at will, and they commence building combs after a few hours' notice. Without any pretensions to accuracy or certainty I think the lamina or plates of wax whereof the combs are built are produced by bees some three or four hours after they have resolved to commence comb-building. The voluntary secretion of wax is, I repeat, one of the wonderful things in the economy of a hive of bees. The combs or wax produced by bees are of different shades of colour; one kind of honey yields wax different in colour from that of another kind. Speaking generally the wax from spring flowers is a shade darker—more yellow than the wax produced in summer and autumn. Field mustard (*Sinapis arvensis*), which flowers in June, yields a wax rather yellow, and the honey from this plant candies very readily. The wax of white clover is not quite so white as that produced from moorland honey. Treacle or common molasses yields a very white wax.

The remarks lately made by one of our intelligent correspondents about the dark-coloured combs which were produced in his supers by artificial feeding has led me to take up this question of wax-production. In laying the foundations of combs, and in attaching new comb to old dark-coloured comb, the bees very often begin with materials rather grey and dirty-looking, but before many inches of comb are built they use nothing but pure wax. In covering the brood in dark-coloured combs they discolour the lids they use in this work. They always temper the colour of the lids of brood cells to correspond with the colour of the combs.—A. PETTIGREW.

THE OLDHAM ORNITHOLOGICAL SOCIETY has just issued a capital schedule of prizes for an exhibition of cage birds and Pigeons, to be held on October 26th to the 30th. Cage birds number no less than thirty-three classes, with prizes of 15s., 10s., and 5s. throughout the whole of the classes; whilst twenty-one classes are devoted to Pigeons, the prize money for which is £1 for first prize, and 10s. for the second in each class. The Secretaries are Messrs. Fleming and Bradbury, Oldham; and the Judges, Messrs. G. J. Barnesby, Derby, and H. Allsop, Birmingham. The entries are announced to close October 16th. In the

schedule it is stated that "exhibitors will be entitled to a ticket of admission for the second day of the Show."

### BRITISH BEE-KEEPERS' ASSOCIATION.

#### EXHIBITION OF BEES AT ALEXANDRA PALACE.

LEAVING to experts the full details and scientific review of this interesting Show, it may be permitted for me as a dabbler and mere novice to notice a few things which struck me as worthy of note. Now first and foremost with regard to hives. No one, I think, could fail to remark how thoroughly the bar-frame system has laid hold of the public, and how very much the straw hives—not merely skeps, but those into the composition of which straw entered—have been superseded by wooden hives. The notion entertained still by some bee-keepers that the bees do not like wood has been overborne by the most convincing testimony, that of experience; and it is not, perhaps, too much to say that in a few years they will be universally used where the old method of killing the bees is not adopted. Coincident with this is the attempt of those who supply hives to combine this with economy. Mr. Abbott set the example with his cottagers' hive, plain and useful at 3s.: this is unquestionably the cheapest hive made. Messrs. Neighbour have them at 7s. 6d., and Mr. Lee exhibits a very good one with complete set of sectional supers at 12s. 6d. The Hartlip hive, invented by the Rev. T. F. Scott, is another cheap and good hive, and really as far as I can see nothing better than such hives is required. Of course any expense may be run into, but it is needless, and these hives answer every purpose. Of hives a little more expensive Mr. Abbott's with fixed legs seemed to me the best.

Another advance seems to be in the larger use of sectional supers, of which several patterns were contributed by Mr. Hunter, Mr. Abbott, Mr. Lee, and others, several coming from America. Bee-keepers complain that they can get no market for their honey, and it is difficult to dispose of supers weighing 15, 20, or 30 lbs., but when a piece of comb weighing about 2 lbs. is displayed in a section of the super it is likely to meet with a readier sale; in fact several bee-keepers have found this to be the case; and another laudable attempt is that of supplying these supers at moderate prices, a point at which those whom I have already named have been aiming.

And will not bee-keepers see what can be done by the bar-frame system by such men as Mr. Cowan, who from sixteen stocks and five swarms has taken 1300 lbs. of splendid super honey, besides several hundred pounds of run honey? and this from no exceptional district, for I hardly think that Horsham would come under that character; and like our own neighbourhood, I suppose after the limes are over there is no further supply for the bees. I fancy from what I could gather that those who have taken their hives to the heather have not reaped much by it, as the cold wet weather of this month must have seriously interfered with the bees. In the neighbourhood of Weybridge I saw very few bees at work this week, and heather abounds there. Many other supers were shown; but those of Mr. Cowan—two taken from the same stock, and upwards of 60 lbs. each—were certainly wonderful proofs of what may be done.

The rapid increase in the number of extractors, too, is noticeable; and here the palm must be given again to Mr. Abbott, who in his Little Wonder has met all the requirements, and at the moderate cost of 15s. Armed with this the apiarian can dispense with all the trouble and mess of straining the combs—can, if he carefully manipulates, drive all the honey out and return the comb to the hive for the bees to fill again, or preserve for melting down. When one recollects that the first of these implements introduced cost some £4 or £5, and that now for a few shillings as good work can be done, we must see a proof of the earnestness with which our leading apiarists are entering into the race of catering for the bee-loving community at large.

There were many most interesting adjuncts to the bee-keepers' necessities, and it will not be the fault of either natives or foreigners if bee-keeping is not carried out on scientific principles and with successful results. There were bee traps—one invented by Mr. Abbott, jun., made simply with the awns of bearded grass, seemed simple and effective; queen cages for introducing queens into hives, simple contrivances, such as that of Mr. Hunter's; a brush of asparagus for sweeping off the bees into the hives; quilt (by-the-by, this seems to be making rapid advances, and Mr. Abbott I find, who was the prime mover in it, has adopted house flannel instead of carpet); perforated zinc for adapting instead of boards, through which workers can get up, but no queen or drone can—all these were provided, besides honey in large quantities, and one's only regret was that so few persons were there to see them. It may be better on Saturday and Monday. Altogether the Committee, who worked hard, may be congratulated—at least so it seems to me—on this third Show.—D., Deal.

This Association held their third annual Exhibition at the Alexandra Palace on the 15th, 16th, and 18th inst., where a very

large gathering of bee-keepers, as well as of the general public, assembled to witness the magnificent display of honey of the late remarkably good season, and the continued improvements made in the various hives and methods of cultivating the honey bee. The large hall of the Palace had about 500 feet run of tables well covered with the exhibits, and the Italian garden was devoted to live bees, where, when the weather would permit, the various operations of driving, transferring stocks, queen-feeding, &c., were shown to the astonished public, who could not understand the perfect *nonchalance* with which Mr. John Hunter and the gentlemen who assisted him handled the bees and allowed them to crawl in multitudes over both uncovered face and hands. The public viewed all these manipulations through the glass of the conservatory, an extra 6d. being charged for admission to the garden, but very soon both ladies and gentlemen, who before this would have shuddered at the thought of a bee's sting, eagerly paid the extra money to be allowed to show their confidence and courage by standing in the midst of the thousands of flying bees, many exclaiming they would never again be afraid of bees. Among the visitors present in the garden were the Duke of Devonshire, Lord Lucan, Lord Ranleigh, and other well-known gentlemen.

Besides English bees, Messrs. Neighbour & Sons exhibited Italians and a stock said to be Cyprians, but in the latter there were many bees evidently mongrels, which prevented a prize being awarded, although it is possible that these were intruders in the hive. A stock of Hungarian bees also arrived too late for competition. There were fifty-one entries for hives of various classes. This is many less than at the first Show, but before that took place bee-keepers' inventions had not been brought to each other's knowledge, and many had hives which they thought perfect, but by comparison were found far behind, and so were superseded. These have now been weeded out, and we may almost say that every hive exhibited at the Alexandra Palace would usefully answer its purpose.

Hives for observation purposes, Class 1, attracted but three exhibitors. The first prize was awarded to Messrs. Neighbour and Sons, but many critics thought that Mr. Wilson's hive (second prize) was entitled to the place of honour. Class 2, for the best moveable-comb hive for depriving purposes, taxed all the talent and ingenuity of hive-makers both amateur and professional. The award of "certificated best" was made to Mr. C. N. Abbott, this hive, with some alterations, having obtained the first prize last year. Its great point then was the introduction of serrated ends to the frames, which fitted into corresponding notches in the front and back, a slip of both folding on hinges. We then pointed out that the extent of propolisation these would receive would be detrimental to its properly working. In this year's hive this arrangement is absent, so that it appears to labour under the anomaly of taking a prize last year for an addition which failed, and this year for the removal of this particular part. Mr. J. M. Hooker took second prize for a very ingenious and beautifully made hive, styled "The Alexandra." Probably its high price (50s.) was a bar to its obtaining the premier place, for there could be no question of its superiority, and there was quite value for money for those who could afford such a luxurious dwelling for their bees. By a peculiar arrangement "The Alexandra" permits of lateral extension right or left, which may either be used as an extra storage chamber on the collateral principle, or put to temporary service to draw the combs into, as in German hives, even if the top is surmounted by a filled or filling super. When the Germans remove their frames they have to place them in a detached box, but here the box forms part of the hive, and may when done with be folded up and stowed away in its special place under the hive. Although there is this lateral arrangement, our usual method of removing from the top is not abolished. All four sides of the hive are fitted with double glass windows for observation purposes. In Class 3, for storifying hives, Mr. Jas. Lee took first prize for a hive which was no exception to his well-known masterly joinery; Mr. Hooker again securing the second place for a hive adopting many of the principles of his formerly described exhibit. In Class 4, collateral hives, the silver medal went to Mr. Hooker for a grand structure, which should be able to fairly test the merits of this principle. Mr. Cowan took the bronze medal, and a commendation was made of the Italian grotto hive, sent by Capt. Danyell, for simplicity and cheapness. Class 5, for the most economical, best, and cheapest complete hive on the moveable-comb principle, for cottagers' use, had ten competitors. The silver medal was taken by Mr. J. Lee for a really good and complete hive, eight sectional supers and cover, for 12s. 6d. For the work and material this was marvellously cheap, but it is very questionable whether a hive costing 12s. 6d. can be "suitable for cottagers' use." By "cottagers" we presume the Association means labouring men, and if so the award was an error. Mr. C. N. Abbott took second prize, and a commendation also for another hive. Class 6, for a hive on an entirely new and improved principle, had no award. In Class 7 Mr. Cowan took the silver medal for a good cheap hive, eke and super costing 3s. Mr.

Cowan, who is an earnest bee-keeper and liberal-minded gentleman, supplies this hive free of cost to any cottager in his neighbourhood who he thinks will make good use of it to start bee-keeping. A high commendation was given in this class to Messrs. Neighbour & Sons for a large and well-made hive, having a wire grating on the crown to prevent the entrance of the queen into the super.

The class for the best collection of hives and bee furniture brought forward the usual fine show from Messrs. Neighbour and Sons, which was matched by that of Mr. J. Lee, to whom the Judges awarded the prize; probably they were influenced by the fact that his collection was mainly the work of his own hands, and his skill in his speciality has never been surpassed.

A notable innovation in the exhibition of supers was the introduction of sections, such as are used in America, and which have been advocated in our columns by Mr. John Hunter. When producers will learn to send their supers to market in these little cheap boxes, then they will find no difficulty in disposing of their harvests.

There was a very good show of extractors, Mr. T. W. Cowan sending no less than six patterns, varying in price from £1 to £3. He obtained the silver medal for an easy-going machine, which reverses the comb without removal, thus saving time and trouble. The second prize was awarded to Mr. C. N. Abbott for a modification of the Italian smielatore. The price of this machine is 15s., which doubtless will tend to make it popular to those who do not mind a considerable expenditure of muscular energy. A good collection of feeders, drone traps, smokers, &c., was shown, to the best of which prizes were awarded, as was also to Mr. F. Cheshire's method of obtaining a wax foundation for combs. Annexed we print the full prize list, leaving our observations on the honey show until our next number.

**HIVES.**—Hive for Observation Purposes, all Combs to be visible on both sides.—1, Neighbour & Sons; 2, B. Wilson. Moveable Comb Hive (to include covering) for depriving purposes.—Certificated best, C. N. Abbott; 2, J. M. Hooker. Hive for use on the storifying principle.—1, J. Lee; 2, J. M. Hooker. Hive for use on the Collateral principle.—1, J. M. Hooker; 2, T. W. Cowan. Most Economical (best and cheapest) Complete Hive on the Moveable Comb principle for Cottagers' use.—1, J. Lee; 2, C. N. Abbott. Best and cheapest Skep for depriving purposes.—Fritz, T. W. Cowan.

**BEES.**—Stock of Ligurian Bees.—1, Neighbour & Sons. Stock of English Bees.—1, Neighbour & Sons.

**HONEY.**—Largest and best Harvest of Honey in the Comb, from one stock of bees, under any system or combination of systems.—1, T. W. Cowan; 2, P. H. Phillips; 3, Rev. G. Raynor. Exhibition of Super-Honey from one Apiary.—1, T. W. Cowan; 2, P. H. Phillips. 3, J. Walton. Straw Super of Honey.—1, P. H. Phillips; 2, J. Walton; 3, W. Martin; 4, D. Free. Wood (or wood in combination with glass or straw) Super of Honey.—1, J. Walton; 2, J. Wrigley; 3, F. Cheshire; 4 and 5, T. W. Cowan; 6, W. H. Clark; equal 7, J. Asbee, Rev. C. N. Gray, R. R. Godfrey. Glass Super of Honey.—1, S. Thorne; 2 and 4, W. Sells; 3, J. Walton; 5 and 7, T. Plunridge; 6, Neighbour & Sons. Exhibition of Run or Extracted Honey, in glasses of 5 lbs. to 10 lbs. each.—1, S. Thorne; 2, J. Walton; 3, Neighbour & Sons; 4, J. Lee; 5, J. Morgan. Exhibition of Run Honey in glass jars, containing 5 lbs. to 10 lbs. each.—1, J. Walton; 2, H. Ellingham; 3, J. Thorne; 4, W. Scorer; 5, S. J. Baldwin; 6, M. Freeman.

**COTTAGERS' CLASSES.**—Largest and best exhibition of Super Honey in Comb, the property of one exhibitor, and gathered by his own Bees.—1, W. Martin; 2, J. Walton; 3, M. Freeman; 4, W. Read; 5, S. J. Baldwin; 6, H. Ellingham. Super of Honey.—1, W. Martin; 2, J. Thorne; 3, J. Walton; 4, S. J. Baldwin; 5, S. J. Baldwin; 6, J. Morgan. Exhibition of Run Honey in glass jars, containing 5 lbs. to 10 lbs. each.—1, J. Walton; 2, H. Ellingham; 3, J. Thorne; 4, W. Scorer; 5, S. J. Baldwin; 6, M. Freeman.

**COMESTIBLES.**—Sweetmeats made from Honey, with recipe attached.—Prize, Mrs. W. W. Jones.

**MISCELLANEOUS.**—Best and largest collection of Hives, Bee Furniture, Bee Gear, and Apiculturalist's Necessaries; no two articles to be alike.—1, J. Lee; 2, Neighbour & Sons. Drone Trap.—Prize, F. Cheshire. Bee-feeders, the invention or adaptation of exhibitor.—Prize, C. N. Abbott. Method of Quietening Bees during manipulation.—Prize, C. N. Abbott. Best and cheapest Supers for general use in an apiary.—Prize, J. M. Hooker. Certificate, J. Lee. Cheapest, neatest, and best Supers for producing Honeycomb in a saleable form.—Prize, C. N. Abbott. Honey Extractor, portability and cost to be taken into consideration.—1, T. W. Cowan; 2, C. N. Abbott. Pure Bees' Wax, in cakes of not less than 1 lb. in weight.—1, W. Scorer; 2, T. W. Cowan; 3, W. Martin. For any New Invention calculated to the opinion of the Judges to advance the Culture of Bees.—Silver Medal, C. N. Abbott. Bronze Medals, O. Poole, S. A. Shole, J. M. Hooker. Method of producing Wax Foundation for Combs, either attached, or capable of being easily attached, to bars.—1, F. Cheshire; 2, Neighbour and Sons.

**JUDGES.**—Hon. and Rev. H. Bligh, Rev. P. V. M. Fillenl, Rev. J. D. Glennie, Rev. D. W. Pennell, Rev. G. Raynor, Rev. J. L. Sisson, Mr. W. Carr, Mr. J. G. Desborough, Capt. P. E. Martin, Mr. J. F. Newland, Mr. O. Poole, Mr. O. Symington, Mr. W. B. Tegetmeier, Mr. C. Tite, Mr. T. F. Ward.

## SEA LAVENDER FOR BEES.

SOME years ago you allowed me to inquire what your apianian correspondents thought of sea lavender (*Statice Limonium*) as bee pasturage. It blossoms about the same time as heather. No one seemed to know anything about it, so I now send you a sample of honey made chiefly, if not entirely, from this flower, and shall be glad to have your opinion upon it. I have not found it so much approved of as clover honey, the slightly bitter taste offending some palates. But tastes differ, and the sea lavender is at all events a great resource for late swarms or stocks which have done badly in the early summer, when sufficiently within reach and when the weather is propitious.

I live myself about two miles from the coast, and have been singularly unfortunate with the hives I have taken down to the sea, in the hope that they would strengthen themselves against the winter from this source and save me in sugar. Three

stocks "skedaddled," not liking their new quarters, one I had to take home and feed, and the most promising of all, which really did gather honey, has this year been robbed and starved to death. I have, however, a friend living very near the salt marshes whose bees, "being to the manner born," get a good deal of honey from the lavender, quite enough to compensate them for their diminished area of pasturage, and to set them up, when, as sometimes happens, the latter part of the summer is more favourable than the earlier.

Putting aside the inferiority of the flavour of the honey, sea lavender can never, I take it, compete with heather as bee forage, if only for the simple reason that it supposes tides, which throw the poor bees quite out of their reckoning, and the capricious and often boisterous winds which prevail on the sea-coast. Yet I cannot but hope that these few lines will be some encouragement to intending bee-keepers who live within easy distance of a salt marsh. Many of these have been reclaimed, and now grow something more valuable than sea lavender. But wherever this beautiful though scentless flower still adorns the flat and monotonous waste with its delicate colouring, let the merry hum of the bee add another element of cheerfulness.—E. H. R., *West Norfolk*.

[The specimen sent was very clear and pale. The bitterness mentioned was so slight that we should not have noticed it if our attention had not been drawn to it. To our palate it is an agreeable flavour.—Eds.]

### HONEY BEES AND MUSIC.

The question whether bees have the power of hearing is a mooted point among naturalists. Sir John Lubbock has tried experiments with his bees in order to elucidate the matter. Thus, he has played the violin close to his bees, he has tried a dog whistle, a shrill pipe, a tuning fork, and shouting, but no noise seemed to disturb them in the least. Nevertheless, a curious occurrence took place a few days since at Windsor.

Col. Stewart, commanding officer Second Life Guards, reports that a few days since, when the regiment was returning down the Long Walk from a field day, a swarm of bees, attracted by the music, followed the regiment into barracks, flying about over the heads of the band. On arriving at the barrack-yard the band formed up to play the regiment into barracks; the bees followed their example, formed up also and settled on a branch of a tree over the heads of the bandmen. They were at once taken prisoners by the corporal of the guard, and are now hived in the barrack-yard. The distance over which the bees followed the band was more than a mile. We have heard of spelling bees, but these are musical bees with a vengeance. It is a common practice in the country to collect bees by means of rattling a warming-pan with a piece of iron, or shaking a stone in a tin kettle, and the idea that bees will follow sounds is as old as Virgil.—(*Daily News*.)

### OUR LETTER BOX.

ADDRESS (*W. L. Seabrook*).—We cannot state the address of "W. H. A."

SCALY LEGS (*L. O.*).—Wash them with soap and water; give a tablespoonful of castor oil, and reduce the diet. A small feeding of barley in the morning and a small feeding of barley meal at night are all that fowls require having such a large grass run.

DORRING COCK (*J. D.*).—We fear the symptoms are indicative of roup. Keep him separated from the other fowls. Give him bread soaked in ale once daily and other nourishing soft food. If his attack is only weakness in consequence of moulting that treatment will restore him.

POLAND FOWLS (*J. L.*).—They all have crests, and should have only four toes. The produce of sunflower seed must depend on the soil and management. One very large flower produced more than 2300 seeds.

HOUDANS (*J. L.*).—There is a portrait of the cock and hen in our "Poultry-keeper's Manual." The following are there stated to be the characteristics:—"Proportions and General Characteristics.—Body rather round, compact, of ordinary proportions, short-legged, and standing firmly on strong feet; pectorals, thighs, legs, and wings well developed; large head; half topknot; whiskers, beard, triple comb, transversal; five toes on each foot; spotted or splashed plumage, black, white, or yellow-white in the adult—in chickens, black and white only. An adult will weigh from 6 lbs. to 7 lbs.; flesh abundant; bones light, about an eighth of the whole weight. A chicken of this breed is put up to fatten at four months, and killed at four and a half months. If we take away from the weight of the carcass the liver, gizzard, the flesh of the head, of the neck, and of the feet, indeed all that constitute the giblets, which find a ready sale, being considered delicacies by some people, there will remain from 2½ lbs. to 3 lbs. of solid compact meat. In this breed the bones of the chicken may be calculated as being hardly an eighth part of the body, while in butcher's meat they weigh a quarter. Comb.—Triple, transversal, composed of two elongated and rectangular flattened spirals, opening right and left like the leaves of a book, notched on the sides, and thick and fleshy. A third spiral springs up in the middle of the preceding ones, taking the form of an irregular strawberry, and the size of an elongated nut. Another small spiral detached from the others, and the size of a lentil, should appear above the beak between the two nostrils. The wattles should be united to the comb, by fleshy parts which form the face, surround the corners of the beak with apparent notches, and the eye with a naked lid. The ear-lobs short and hidden by whiskers. The half topknot thrown backward, and on the sides a few pointed feathers turning at the points, but sticking-up in the air. Face.

—Naked, surrounded with whiskers formed of short-pointed and up-turning feathers. Beard.—Begins under the beak between the wattles, joins the whiskers, and hangs down the neck; wider at the bottom than at the top. Beak.—Strong and rather hooked, black at its insertion, and yellowish at its extremity, depressed towards the beard, and dropping considerably at the corners. Physiognomy of the Head.—Differing from many other species by several remarkable features; the head and neck form rather an open angle, so that the drooping beak is seen above it, and takes the appearance of a nose. Comb.—The square and flattened comb seems to be a fleshy forehead, the cheeks (in England, face) are surrounded with curling feathers which look like whiskers, the drooping corners of the beak resemble a mouth, and a cravat of feathers joined to the wattles simulates a beard; the topknot is like a rough head of hair, and the entire face at once suggests the idea of that of a man. Colour of Legs.—In adults, a leaden grey; in chickens, bluish and whitish grey, with rose-coloured spots. Plumage.—It should invariably be composed of black, white, and straw-colour; those fowls that have any mixture of red should be got rid of. The plumage of the Houdan is of the variety called splashed or curl-papered. It is irregularly composed of feathers sometimes black, sometimes white, sometimes black tipped with white, and sometimes white tipped with black. The Hen.—Body: well set, appearing almost as large as that of the cock, firmly planted on strong legs; breast, thighs, legs, and wings well developed; large head; demi or whole topknot; whiskers and beard very distinct; rudimentary comb and wattles; five claws on each foot; feathers of the abdomen very fluffy, ample and pendant; other feathers of ordinary length; splashed plumage, black and white with violet and greenish shades. Physiognomy of the Head.—When the topknot is very developed, the hen is unable to see in front or on either side; she can see only on the ground, because the feathers cover not only the lid but the eye itself; this gives the bird a nervous motion at every noise it hears. It is only by close observation her eyes can be discovered at all.

GOLDFINCHES (*C. G. B.*).—The terms "Cheverel," "Chibald," or "Chevalier" are applied to Goldfinches possessing a white speck or mark immediately beneath the lower mandible, sometimes so large as to completely divide the bright scarlet-red facing which mostly surrounds the heads of the Finches. We do not consider birds so marked as of a distinct breed. Upon this subject we shall further remark in our next issue.

CANARY MULE WITH SORE NEAR THE EYE (*Adis*).—Rab the place with citrine ointment, obtainable from any chemist.

MELILOT FOR BEES (*A. R. H.*).—The flowers of nearly all the trefoils yield abundance of bee pasturage, but especially the white clover, *Trifolium repens*, and the common melilot, *Trifolium officinale*. They are common in most pastures.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

- 13th.—Fine but cold morning and forenoon; very dark between 3 and 4 P.M., and again after 6 P.M.; rain in the evening.  
 14th.—Fine forenoon, but rather cloudy about 1 P.M.; taken as a whole a pleasant day.  
 15th.—Dense fog, clearing off about 11 A.M.; slight sprinkle of rain between 2 and 3 P.M., but a pleasant day.  
 16th.—Wet and uncomfortable morning; showery and disagreeable all day even to midnight.  
 17th.—Beautifully fine morning and forenoon; rather cloudy at 2 P.M. and a slight thunderstorm (but not heavy rain here) from 3.20 to 3.45 P.M.; wet afternoon, dull evening, but fine night.  
 18th.—Fine morning and (but for a heavy shower between 1 and 2 P.M.) a fine day, and starlit night.  
 19th.—A beautifully fine day and starlit night; slight aurora about 7 P.M. Mean temperature slightly lower than the previous week, barometer rising rapidly at the end with indications of finer weather.—G. J. SYMONS.

### COVENT GARDEN MARKET.—SEPTEMBER 20.

THE market continues thinly supplied with nearly all classes of goods with the exception of Apples, there being a larger quantity arriving than was anticipated, but prices remain much the same, business being generally very quiet. Apples are fetching from 1s. 6d. to 5s. the half-sieve, and Pigs from 1s. to 3s. per dozen.

From observations taken near London during forty-three years, the average day temperature of the week is 64.4°; and its night temperature 43.4°.

## MELONS DESTITUTE OF FLAVOUR—GROWING IN COLD FRAMES.

MELONS have not been good this year." The observation surprises me, for I have never had a finer crop of higher quality, and that under very ordinary—i.e., hotbed culture. I have three two-light and five three-light frames over dung beds devoted to Melons, and the plants have averaged three fruits per light for a first crop, and in ten lights I have had a second crop of an average of three fruits per light, and in four lights I have a third crop of three fruits under each light; these fruits, as might be expected, being small, or weighing 1½ to 2 lbs. each—just the size for breakfast, some persons being particularly fond of a Melon in the morning, and a small fruit is as good, often better, than a six-pounder. The 105 fruits afforded a fruit daily up to the middle of September, commencing July 3rd—about a fortnight later than usual. The heaviest fruit was Beechwood × Read's—7 lbs., and the smallest 1½ lb., a cross of Moreton Hall with Wills's Oulton Park × Colston Basset; the smallest were the most esteemed, and of those I had only a dozen, the remaining ninety-two all exceeding 2 lbs. weight. The only two named kinds grown are Eastnor Castle and Heckfield Hybrid, some fruit of the last reaching 6 lbs. I grow those—Eastnor Castle for its high quality and continuity of bearing, and Heckfield Hybrid for its free-bearing and hardiness, it being harder than Little Heath.

I have a 60-feet run of lean-to frames divided into fourteen lights, which are used for Lettuces to come in early in spring, and for raising plants, or hardening-off plants afterwards up to the end of May. The frames are only 4 feet wide, and are not heated. Loam enriched with stable manure was used for the Lettuces, and into this soil I put out a Melon plant under each light from a 4-inch pot on the 10th of June, and they have given two fruits per light of over 2 lbs. each, some weighing nearly 4 lbs. I find Heckfield Hybrid is not nearly so oval when grown cold as when grown with both top and bottom heat. It is hardier and larger than Little Heath, is earlier under the same conditions, and of better quality; it is free in growth, though small in foliage, and the fruits set and swell freely. I selected it and Little Heath for planting in the cold frame as being the two hardiest, in order to compare the doings of some cross-breds with them, my object being to obtain a Melon with the high flavour of Scarlet Gem, or its better form Read's Hybrid, scarlet-flesh, Meredith's Hybrid Cashmere in green-flesh, and Golden Gem in white-flesh—one that would succeed from sowing the seed early in April, planting-out in May, and ripen with as little protection as that afforded Vegetable Marrows. Read's being the hardiest form of Scarlet Gem, I crossed it with Golden Gem, and the result is a variety of the type of both parents with much hardier constitution, ripening perfectly in a cold frame without any heat other than that of the sun. Golden Gem is not much netted, but the cross with Read's gave

fruit as finely netted as the latter and of handsome appearance. Then Beechwood × Read's gave a green and scarlet-flesh, representative of both in the progeny, both succeeding in a cold frame. Any amateur who, using his frame or frames for raising half-hardy plants from seed, and is desirous of growing Melons in the frames after the middle or end of May, but is deterred by the idea that artificial heat is necessary, may be disillusioned if he applies for a few seeds, of which I shall be happy to give so long as they last—namely, Golden Gem × Read's and Beechwood × Read's; and any who can command a hotbed in May, to line it with grass-mowings afterwards, can have seeds of Moreton Hall × Wills's Oulton Park × Colston Basset, a blunt-ended oval small kind, ranging from 1 to 2 lbs. in weight, just the thing for a Melon connoisseur; but it is only right to state that it has so hard a rind as when ripening to be liable to crack, which may, however, be prevented by keeping dry at that time and leaving a little air on at night to prevent moisture from condensing upon the fruit during the night. Any amateur sending a stamped directed envelope is welcome to a few seeds. I may mention that a grand Melon for breakfast is Colston Basset. Big Melons like large dessert Apples are often poorly flavoured.

Melons are often ruined by too much heat. They grow luxuriantly, but the fruit turns yellow instead of swelling, and the result is only a fine crop of foliage. To have Melons in May and early in June bottom heat is absolutely necessary; but after the middle of May a spent hotbed is as good as a bed of fresh material. What most Melons like is a broiling sun and plenty of water at the roots. I water them with a hose pipe, the water often being 20° below that of the temperature in which the plants are growing. Everybody knows that when plants are grown in bottom heat to water with the fluid less in temperature by 20° would lead to disastrous consequences, but it does not in the least affect plants without bottom heat. Constant dribblings of water overhead may prevent evaporation, but they are practically useless as means of supplying food to the plants and fruit. Drizzling waterings, syringings, &c., may be necessary in hot-water-heated structures where the air is being made constantly lighter and the moisture is reduced in proportion, but in unheated frames the case is very different. I usually give such a watering that it runs through a dung bed. Twice a-week this watering is given in very hot weather, but, as a rule, only once. As for sprinkling overhead at closing I have never thought about it since I gave up growing Melons in pits with top and bottom heat furnished by hot water. We do not want Melons until the middle of June, and such pits are put to better purposes.

I find the beginning of March is as early as the seed need be sown for growing the plants in frames or dung-heated pits. The plants are potted singly in 4-inch pots when the first rough leaf shows itself, and in sowing and potting the soil is thoroughly moist and warm. The fruiting bed is made up when the plants are potted, and the soil is put in when the heat of the bed is not more at 6 inches beneath its surface than the hand can bear;

about two barrowfuls are placed under each light, covering the surface of the bed about 2 inches deep, and the rest is formed into a cone in the centre with the top flattened so as to be about a foot from the glass. The plants have the points taken off at the second rough leaf, and one plant is put under each light, planting to within half an inch of the seed leaves, these being left clear; the soil being made firm about them, and that forming the ridge is also firmed.

I am careful that the soil is moist when placed in the frames, and then no water is given until the plants reach the sides of the frame, when the soil is examined and if dry a good watering is given. The plants eventually produce secondary shoots, and it is upon these that the fruit is borne. I take two primary shoots to the back and two to the front of the frame, and rub off all others, also the leaves for a distance of 6 inches from the stems all round, and not a leaf or a shoot is allowed to grow on those parts of the stems. That is done to keep off damp or canker at the collar, and the stems not wetted in watering more than can be helped. The secondary shoots will show fruit at the second or third joint. I now see that the bed is lined and the soil moist. When half to a dozen flowers open upon a plant I impregnate them about noon, the frame having had air for some time, and stop each shoot one joint beyond the fruit. At night after this time half an inch of air is left on each light, continuing to look daily for opening flowers, and impregnating them when fully expanded. When the fruits are of the size of an egg I remove all but three or four on each plant. The shoots carrying fruit are kept stopped to one joint beyond the fruit, and other growths are removed, those below the fruit being rubbed off, except a few near the collar, which are stopped rather close, the object being to have the basis of a second crop. The plants are gone over once a-week for dressing and watering. The fruits are placed on pieces of slate and exposed to the sun. The fruits change colour about ten days before ripening, then no water is given, especially to those ripening in cold frames; but if the soil be dry a last watering is given, particularly when a second crop is desired.

At this stage I commence when a second crop is wanted to cut away the laterals a few at a time, and make choice of about four shoots emanating from near the collar of the plant and encourage their growth. These shoots take the sap which would, by the removal of the laterals, be diverted to the fruit, and cause it to crack. The fruit is cut the day after its aroma is perceived, and is placed in a fruit room until fit for table. The fruit being cleared the old shoots are cut away to those we have prepared to supplant them, and a moderate watering is given, using cold water after the middle of June. In very bright weather the plants are now watered twice a-week, if cloudy with alternate clear intervals once, and if dull and wet not at all.

As to air, it is given at 75° and taken off at that, allowing in the meantime the temperature to mount up to 85° or 90° and not higher if it can be helped. As to night temperature I never trouble myself about it. Up to June the beds are kept well lined against the sides of the frames, and the lights have a double thickness of mats over them. Two beds are made up at a time and at intervals of a fortnight to three weeks, the last in May.

This is the last time that I shall grow named sorts, and I strongly advise others to cross and recross, being certain that they cannot fail in originating kinds that will be improvements upon the parents. I have found that any advance to higher flavour must be sought by a concentration of the juices in a smaller fruit, advances in size only enhancing coarseness. I may say that I have material for a trial under hand-lights another season, giving the plants the same treatment as Vegetable Marrows, and I anticipate favourable results. Having heard so much of the poor quality of Melons this season I thought a very simple mode of culture might not be unacceptable.—G. ABBEY.

## TWELVE ROSES ANY VARIETY.

I quite agree with your correspondent Mr. Gould of Mortimer, that the above is a class which ought to be specially fostered, and that in every public show there should always be a twenty-four class for nurserymen and a twelve class for amateurs. The change of it into twelve triplets at the Crystal Palace this year was hardly a change for the better. This class greatly increases the number of exhibits, as the twenty-two boxes side by side this year at the Alexandra Palace abundantly

proved. A twelve box is a most manageable size for taking about. It shows Roses to great advantage, whereas the eye is fairly bewildered by thirty-six and forty-eight. It ought always to contain twelve perfect blooms, which, except with large growers, cannot be insured even in a twenty-four box. Of course there should be four prizes if it be an object to obtain a large number of exhibitors.—A. C., *Brockham Vicarage*.

## FRUIT TREES FOR SMALL GARDENS.

"W. W." asks for information about the most suitable kinds of fruit trees for a wall facing the south; he also wishes to know which are the best sorts of Plums, Peaches, Pears, and Cherries, and further requires to understand the proper management of the soil preparatory to planting, and when to plant. There are many other owners of small gardens who want a little help in this matter, and as the planting season will soon come round again I purpose making my reply as comprehensive as possible.

Turning first to the soil, I do not hesitate to assure "W. W." that its treatment is in the majority of cases a very simple affair. Soil that will yield good vegetables will yield good fruit, and such soil is almost invariably to be found in every part of the suburbs of large towns. As a general rule it will therefore only be necessary to deepen the soil at the station of each fruit tree, and in doing this I would always prefer raising the station considerably above the common level, say 9 inches or a foot, and thus not only avoid deep excavations—always a laborious and costly matter, but also by thus elevating the tree contribute very materially to its future health, vigour, and fertility. "W. W." suggests flagging or concrete as being necessary to place beneath the soil of a fruit-tree border. It is undoubtedly a good plan to use concrete in low-lying districts having a badly drained and water-logged subsoil; but under ordinary circumstances concrete is quite unnecessary, and is really a source of disease when placed under a shallow well-drained soil, inducing a stunted growth, abnormal fertility, and premature decay. Let, then, the stations be somewhat elevated above the common level, the area of each station being 6 feet square, and the soil 2 feet deep. See that the drainage is thorough, which it will be if the water from heavy rainfall passes through it with tolerably rapidity, which is easily ascertained by making a small hole in it, and if no accumulation of water follows it may safely be concluded that the drainage is efficient.

Do not be persuaded to plant too early, let the growth of the current year come to maturity in the nursery before the trees are lifted. November is the best month of all the twelve in which to plant fruit trees; all good growth is then perfected, the buds are plump and full, the foliage is falling, the growing season is fully past, and the trees are at rest.

Plant when the soil parts readily from the tool, and not when it is so saturated as to cling together in large clods. Select healthy, vigorous, and small rather than very large trees; prune any very long, decayed, or bruised roots; see that none of the remainder are twisted or cramped, but that all lie straight in the soil. Do not bury the stem, 3 inches of soil over the upper roots is an ample covering. Press the soil gently but firmly about the whole of the roots. Prune all weakly spray, thin crowded growth, and shorten the leading shoots to induce a vigorous start in the spring, sufficiently near the base of the branches to have them well furnished with an abundant and strong lateral growth. Fasten each tree securely to a wall or stakes as it is planted, so that the roots are undisturbed by wind.

A selection of the best sorts of fruit is a matter in which individual taste is so intimately concerned that I cannot hope to afford general satisfaction or to obtain an unchallenged approval of my lists. I must, therefore, rest content with naming only sorts of proved merit, leaving novelties which are at all doubtful to be included in future selections should they prove worthy of a place.

*Peaches*.—To those wanting only one tree *Grosse Mignonne* may be strongly recommended as a hardy variety, having a free growth and bearing abundant crops of large, highly coloured, handsome fruit. It is what is termed a mid-season variety, coming into use about the middle of August. For earlier fruit take *Early Beatrice*, which affords a supply of ripe fruit by the middle of July onwards to the first week in August; and for a late kind, ripening in September, we cannot have a better than *Barrington*, which is a vigorous grower, forming a large tree quickly, and bearing its very large beauti-

fully coloured fruit freely. I am strongly tempted to add more of my favourites, but refrain, as I remember I am writing for very small gardens, and am anxious that these notes may prove of real assistance to the owners, who ought certainly to waste none of their space upon any but the choicest of fruits, flowers, and vegetables.

*Nectarines.*—Many sorts of great excellence worthily claim attention, but I think on the whole that Stanwick Elruge is quite the best of them for a small garden. It never disappoints, always yielding an abundant crop of really fine, handsome, and rich-flavoured fruit, and the wood growth is healthy and vigorous. For an early kind we have none equal to Lord Napier; and for a late one to follow the Stanwick Elruge, Pine Apple worthily ranks first.

*Figs.*—In the south of England we are able to obtain a supply of ripe Figs from trees growing in the open air; the best and most reliable variety being the old Brown Turkey. I have had very old and very young trees of it, and have found all of them extremely fertile. For a couple of other sorts I can recommend White Marseilles and Grizzly Bourjassotte. The growth of this last is with me only of medium strength; it would, therefore, probably prove suitable for a small garden.

*Cherries.*—Of these the best sort for a small garden is in my opinion *Impératrice Eugénie*. Its growth is robust and compact, yet tolerably free, and its large, handsome, and delicious fruit clusters so thickly upon the branches as to render the picking a tedious and difficult operation. For a couple of other sorts I cannot do better than to take the Kentish and the Morello, both of well-known excellence for all culinary purposes, the Morello also affording some excellent dishes of late fruit for eating. I may add that this trio is selected from nearly thirty sorts which I have in cultivation.

*Plums.*—There are so many kinds of Plums of equal merit that selection is most difficult. For dessert I may take the old Green Gage, with Bryanston Gage and Purple Gage; for cooking, Early Rivers, Victoria, and Belle de Septembre.

*Apricots.*—Kaisha has proved best with me in health, vigour, and fruitfulness. The fruit is large and excellent, and I am induced to draw special attention to it as it flourishes in soil that is not considered favourable to the Apricot, other sorts being much diseased or dying outright in a season or two after planting.

Pears and Apples, with some hints as to aspects, will be noticed in a future communication.—EDWARD LUCKHURST.

### THE ROSE ELECTION.

An' why shouldn't I zay zummut about the Rose, though I be but a poor ignorant Zummerzet chap? I've allus loved the vlower, and cultivated eet likewise zo var as my means and my toime would permit. Aye! an' I've zhow'd eet too at exhibitions near where I bide, an' now an' then have had a prize.

An' I tell'e what the Rose wants, an' that is a loo zittuation an' a roit down good zoil. Not too much dung; I doant hold with overveeding ought, be eet pigs or vlowers. Moderazun is my maxum in all things, an' vor all, whether man, brazten, or vlowers.

I'ze but a wee beet o'groun', such as the chaps who writes zo larned to'e about Roses would tarn up their nozes at, but yet eet is large enuff for taters, greens, an' Roses too. What does I think is the best stock vor Roses? Why, stocks err all one to I. The only thing I'ze cares about is to have a *large stock* ov them—at least as many as my groun' 'ill hold. In the fall I goes round the highways, an' byeways too, an' where I dare I pulls out a good young Dog Rose Briar, takes him home, an' puts he in the ground before he knows he's been disturbed. I doant care about hacking the roots like zome does, but just cut with a knife or sharp hook—the oldest works off—leaving the tender young roots, which should be on all Briars, to grow. I buds he next zummer, an' not till the following spring do I manure him, but then doant I just liquor him up in the growing time, particular when the bud begins to swell. I'ze a wee bit ov a zesspool, or zome zich contrivance, into which all the zlops err thrown during the whole year, an' about once a-week I gee's them Roses zich a zoaking. An' doant they buds thrive! I never stops the shoot; I ties eet up as eet grows to a stake, an' encourage eet in iv'ry way the vurst year to grow; but the zecund year I cuts eet down to about a' ninch vor the baze. Then doant eet jist zhoot an' burzt on all zides, zummet like 'Sparagrass buds. An' now as to zorts. Well, I knows a good vew, but iv I was to name 'em to'e perhaps ye'd zay to I, "We knows that bevore,

my lad, thanks vor nothing." Well, may be you're roit, but yet I mun just name a vew.

There's those blezzid Tea-zents. Oh! what loovely blooms they be in this coontry. I knows, or at least chaps zay, that oop the coontry the Tea wo'n't do out ov dooars; but yer an' down the coontry they grows an' flourishes loike meadows drezzed with guano. An' yer I mun tell'e a bit ov an aneodoot about this blezzed guano. A varmur chap went to buy zome ov a agent, an' couldn't remember how eet were named. "Yer, maister," he zays, "I wants zome ov that 'ere stuff. I doant know what the hangment ye calls eet, but eet stinks zummet loike owlets' muck." Eh, zurs, an' what foiner stuff this 'ere guano is vor them Teas, too, in the spring ov the year. Vurst there's Cloth ov Goold, that grand goolden vlower, which 'squire tells I iz zo hard to bloom, but with I eet does as well as any other. Eet is a rare beauty is Cloth ov Goold. I niver tiches mine wi' a knife, but when eet grows beyond all bounds jist take a reaping 'ook an' out down great branches ov eet. This Rose is quite different from any other yellor Rose in these parts. Eets growth is most vigorous, eets habit erek, an' eets blooms more comely than eether Maréchal Niel or Solfaterre. Eets only beat by one, according to I, an' that's that lovely, dilicate, charming Marie Van Houtte. A vollum might be written about this Rose; no words, howiver, that I can command will describe eet to 'e. I zend 'e a bloom by this poost, an' you can zee vor yourzelves what she be loike, though, ov course, ye must take into account that she's been tozzed about in the Gurt Western Mail avter travelling thirty miles in a mail cart; but do 'e zay if I be not roit in what I zays ov her.

Then there's those two delaifull zisters; one zeeming to blush at beholding t'other's loveliness, t'other turning pale wi' doubt whether she be as vair as her zister, an' them be Souvenir d'un Ami an' Souvenir d'Elise. Talk to I ov yer Hybird Perpetuals, where's there one that can hoold a candle to these two darlings? Whoy, iv I, gurt hulking coarze brute ov Zummerzet chawbaacon, as noo doubt ye and yer readers will call I, could perduce or zend out, or whativer ye call it, zich a vlower as ayther of those I 'u'd gladly zing, *Nunc dimittis*. The man who zent them out is a man whose praise ought to be zung in ivvry place by oold an' young—I were gvain to zay *deef an' dumb* vor the zake ov the rhyme as 'twere, but that 'u'd hardly doo. An' then, zurs, there's that zweet companion ov theirs—rival we mus' n't, inferior we can't, call her—that Rose whose vorm is loike a "Vennus de Medicine" [we presume Venus de Medici is here alluded to.—Eds.] an' colour a zoft warm flesh loike that tinted statue ov her I zaw when I went to the Gurt Exhibition. Avter her comes a Rose not yet zo well known as those as I've named, but which bids vair zoon to rival 'em, an' that is Souvenir de Paul Neron. 'Tis a moighty long unzootable name, but that's his only vault. I wish 'twere Souvenir de Madam Paul, or zummut else, vor he has no more connection or zemilitude to the gurt hulking begger Paul Neron than a Dayzy be to a Dandelion, or a zweet Vilet to a Toadstool. This is a dilicate white in colour, wi' a dash ov pink deepening to the zentre. Eet should be cut when 'tis about ha'f open, as when vully expanded 'tis loike oold zider, a leetle vlat. Then comes Rubens. Now, zurs, I ventur' to think that this Rose is a leetle neglected, an' does not receive the 'tention he dezerves. In the autumn 'specially, an' I should imagine all the yer round iv shaded vor the zun, the tints ov its various petals err what I calls zooperb—zoft but distinct, vlooding the rose in a zea ov the lightest rose, or vilet rose, if there be zich a colour. But I be a poor hand at describing, and no doubt ye knows all about it, much better too than I. Yet iv I'm ax'd to zay what I calls the best Roses I zay the Teas, out an' out, vor they put to shame, not only in dilicacy ov colour, but perfection ov vorm, all Hybird Perpetuals that have ivver been zeen, or, I think, will ivver be zeen by.—A ZUMMERZET YOKEL.

[The specimen of Marie Van Houtte was the finest bloom we have ever seen of the variety, not excepting blooms which have been so well exhibited by the Rev. J. B. M. Camm from Dorsetshire.—Eds.]

### THE POTATO CROPS IN IRELAND.

For some time past I have been watching the Journal to see if anyone would tell about our wonderful crop of Potatoes this year. In the first place, Potatoes were much later in being planted this season than usual, our spring being very wet and cold. It was almost May before they were all planted. However, the weather became very hot, attended with showers; the

crops grew rapidly, and the result is, we have a crop the like of which we have not had since 1847, the year of the great failure. Our crop is abundant. The flavour is excellent. The tubers are free from disease. It is a novel sight for the young folks to see whole fields as green and healthy as possible at this date, 19th of September. The elder people tell me they have not seen it thus since before the years of 1846-47. I hope your readers will enjoy to read about Paddy having such a plentiful supply of his favourite dish (Murphies).—B. G., Co. Down.

### CULTURE OF THE SOFTWOODED ERICAS.

At no season of the year are flowering plants held in so much esteem as during the winter and spring months. The softwooded *Ericas* are amongst the foremost in attractiveness during those periods, but are seldom seen in good condition in private places, which is generally in consequence of the plants not being cut-back freely. They should be cut to within 2 or 3 inches of the current year's growth in the case of old plants.

The present is the best time to raise a stock of these plants from cuttings. Select the cuttings, of which there is an abundance on well-ripened shoots of the present season's growth, and take them off with a heel, and insert them in 32-size pots which have previously been filled to within 2 inches of the top with crocks. In preparing the pots place a little rough peat over the crocks and fill-up with sandy peat, pressing the soil down very firmly, which is of great importance, with some silver sand on the top. After inserting the cuttings place the pots in a cold frame and plunge them in cocoa-nut fibre, keeping the frame very close and carefully shaded from sun. There they may remain till they are rooted; or if there is convenience, place them, after they have been in the frame a fortnight, where they may receive a slight bottom heat, in which they will strike more readily. After the cuttings are rooted pot them off singly into small 60's, and keep them rather close for a week or two until they are established. Pay great attention to stopping, or the plants will become leggy. In September discontinue the stopping unless one or so of the shoots are taking more lead than the others. At Christmas they must be repotted into 48's, using rough peat with a sixth part of sand added, keeping them in a cold frame, and ventilate freely until the following May, at which time place them out in the open air until there is danger of frost. They must never be allowed to become dry at the roots, or else they will be a failure. After they have done blooming cut them well back and treat as young plants.

*Erica cafra nana*, *gracilis autumnalis*, *gracilis vernalis*, *hyemalis*, *Syndriana*, *Wilmoreaana*, and *colorans* are the principal varieties.—A. Y.

### GATES AND STILES.

ONE can hardly travel a few miles anywhere in the country without seeing gates of bad construction—gates which do not stand up to their work. This is most observable in field gates, but is not confined to them. Some of the elaborately ornamented entrance gates and lodge gates exhibit the same want of principle in their construction. We do not refer to some of those quaintly ornamented gates which are pleasing to the eye, although it may fail to perceive any proper principle of construction at first sight, for in these gates there is a skeleton framework, which is designed with due regard to the true principles of construction, but which is hidden by the more prominent ornamental parts. These are works of art about which there can be nothing false; but we refer to gates put together upon no principle—thrown together, as it were, by guess-work, as if the constructors would trust to chance that the gates would stand up.

But the principles of construction are various, and a knowledge of them does not come by intuition; they are found when sought for, like all other principles of art and science.

The framing of all gates, whether plain field gates or ornamental entrance gates, should have reference to the suitability of the various materials to resist the various kinds of strain brought upon each piece by the suspension of the unsupported parts. Thus the heel-post is wholly supported, and its dimensions are disposed with reference to the mortices and bolt holes to be cut in it, and not upon strains to be brought upon it. The dimensions of the head post are considered in the same way, there being no strain upon it. The bars, however,

and the braces are subject to strains of various kinds. The bars resist a cross strain which is brought upon them by their own weight and by that of the head-posts, and by any accidental load, and the braces resist compressive and tensile strains accordingly as they are disposed as struts or ties.

The straps of the top bar resist a tensile strain. The hooks resist a shearing strain, but their shanks are subject to different strains—that of the top hook resisting a tensile strain, and that of the bottom hook a compressive strain. Thus the shank of the bottom hook need not have a screwed end and nut, as that of the top hook must have, nor need it even pass through the gate-post, for it may be driven in as a spike; but it must have a shoulder, which must abut solidly against the gate-post, while the shank of the top hook need not have a shoulder, but it must be fastened at the back of the gate-post either by a

Figs. 37 and 38.

screwed end and nut or by a cotter, and in either case there should be a washer-plate to afford a greater bearing surface against the wood and prevent indentation.

The top and bottom hooks and straps are seen in figs. 37 and 38.

Fig. 38 also shows the bottom of the gate-post resting upon a broad and thick sill, the foot being spiked thereto with a long jagged spike, and the post being strutted therefrom by a strut 4 inches by 4 let into the sill with a shoulder, and spiked thereto, and spiked also to the gate-post, against which it abuts with a square shoulder.

A bolt with screwed end and nut is better than a jagged spike, although this is often used instead of a bolt and nut. The action and the strains are as follows:—The weight of the gate tends to pull over the top of the gate-post; the pressure is then transferred, through the post and the strut, to the toe of the sill, tending to turn upon it as a centre, which tendency is resisted by the weight of the post and by the weight of earth upon the projecting end of the sill at the back of the post. It is therefore very necessary that the earth at the back of the

post, and indeed all round it, be well consolidated by ramming in the earth in small quantities tightly, or else that the projecting end of the sill be weighted with large stones or otherwise.

Fig. 39 is a plan. The strap of the top bar should not be less than, say, 2 feet in length, and each end should be bent inwards half an inch, and a vertical chase of that depth should be cut in the top bar of the gate, the bolts, *a* and *b*, serving the purpose merely of holding the two straps to the bar, the strain caused by the unsupported weight of the gate being taken by the two turned-down ends of the straps, and counteracted by the power to resist detrusion possessed by the surface of the wood of the length and width of the strap plus 1 inch. The power to resist a tensile force of the sectional area of the top bar left between the two turned-down ends of the straps should not be less than the power to resist detrusion

FIG. 3

Fig. 39.

possessed by the two surfaces of wood above mentioned. This power depends upon the lateral cohesion of the fibres of the wood, and is not more per square inch than about the twentieth part of the direct cohesion or of the power to resist a tensile force. The ends of the strap should be "jumped" or thickened before they are turned down, and should be forged down square, the thickness of the ends being about twice the thickness of the strap. When the ends are thus indented they take a proper hold of the top bar of the gate, and take their bearing at once; whereas if the strain caused by the hanging of the gate be taken crosswise by the bolts, two movements take place before the bearing is taken: first, the wood is compressed by the harder substance of the bolt; and secondly, the bolt undergoes a bending action; and, from the shape of the gate, any horizontal movement here is followed by a much greater drop at the head of the gate.

To prevent this movement—or rather to correct it when it takes place—a bolt, with a screwed end and nut, is sometimes substituted for the close straps, in which case the head of the gate being raised to or a little above its proper position, the nut is screwed up, the intention being thus to retain the head of the gate in its proper position; but, on account of the action being indirect, and the strain of the unsupported part of the gate being brought upon the bolt through the intervention of the arm, upon which a cross strain is induced, the intention is not fully realised, and the head of the gate continues to drop because of the want of rigidity of the arm. To obviate this the bolt is sometimes continued along the whole length of the gate, and is made to take hold of the head-post; but this not only adds to the money-cost of the gate, but also to the weight at the head, which it is always desirable to avoid.

It is better construction to use the ordinary straps, and, before the gate is hung, to cramp the whole frame tightly together in a horizontal position, and drive in wedges of hard wood at all those joints where, on the gate being hung, the pieces of the framing are compressed together; and, to make this more effective, the cramping should be so managed as to set up each joint in a direction opposite to that which the weight of the gate will cause it to take after it is hung. We are now referring altogether to gates of wood. The joints under compression are those between the lower end of the brace and the heel-post, and between the upper end of the brace and the top bar, and also the inside of the turned-down end of the strap.

In respect to the angle at which the braces should be disposed, the more upright they are the less the strains, both on the braces in compression and on the top bar in tension, as may be shown graphically by the following diagrams:—

Let *A, B, C, D* (fig. 40), be a frame with one brace, *A, C*. Now, in the first place, if there were no brace at all, half the weight of the gate would be carried by the heel-post, *B, C*, and the other half by the head-post, *A, D*, which must in that case rest upon the ground; but in order to make the whole weight rest upon the heel-post, so that the gate may turn upon an axis, the brace, *A, C*, is introduced, upon the head of which rests that half of the weight of the gate which would otherwise rest upon the head-post.

The strains upon the framing will be as follow:—Mark *a d*

with a scale of equal parts equal to the weight upon the head of the brace—that is, half the weight of the gate. Produce *B, A* to *b*. Draw *d b* parallel to the brace *A, C*, and draw *d c* parallel to the top bar. Then, by the same scale, *A, b* measures the tensile strain of the top bar, and *a c* the compressive strain upon the brace.

Now let *E, F, G, H, I, K* (fig. 41), represent a gate of the same size and weight, with two braces, *F, I* and *E, H*, connected together by the vertical tie, *E, I*, so that, together with the top and bottom bars, they make one frame. Supposing the pieces to be jointed at the intersections there will be a weight upon the first brace, *F, I*, equal to one-fourth of the weight of the gate, and upon the second brace, *E, H*, there will be three-fourths of the weight of the gate. Mark the vertical distances, *F, e* and *E, i*, accordingly, and draw the parallel lines *e f* and *i g*, also *e k* and *i h*. Then *E f* will measure the tensile strain of the top bar between *E* and *F*, and *E g* that between *F* and *G*, while *F k* will be the compressive strain upon the brace *F, I*, and *E h* that

FIG. 4

FIG. 5

Figs. 40 and 41.

upon the brace *E, H*. So that all the strains are less when the braces are more upright. In what has been said above, the gate is taken to be of the same weight per foot in length from heel-post to head-post to prevent complication, the object here being to illustrate the principles only of framing gates, which form the groundwork of practice; and the rule of practice which is not founded upon principles is the "rule of thumb," which is not an admirable rule, although very prevalent amongst "British workmen." Many English carpenters can and do frame together gates, big and little, very properly, although they may have had no scientific instruction, and whose good work is owing to the good practice which came under their notice and under their hands in their apprenticeship; but for every one of these good workmen how many we see whose practice is as devoid of mind and as wooden as the gates they make!

In gates, as in all other constructions, practice must be blended with theory; neither must control the other, but each must be modified by the other. Thus theoretical instruction modifies a rude practice, and—which is the better condition of the two—a theoretical initiative should be modified by an experience of good practice. Whether the structure in hand be a great bridge or a small bridge, or merely a gate, it requires intelligent construction, and those who frame gates should seek after, until they find, the true principles upon which good work depends, even as those who frame bridges are obliged to do.—(*Building News*.)

### LITTLE HEATH MELON.

I HAVE a faint recollection that last year when I ventured to speak in terms of praise of this Melon as suitable for the amateur of small means and small ground, that a certain most excellent friend of mine said it was so poor in flavour that it was not worth the trouble. Judge of my delight, then, to find that at Dundee, at their great International Show, it took the prize as the best scarlet-flesh Melon. Now, the Judges there were no novices. They knew what they were about, and yet they gave it the place of honour—one, indeed, I should never have thought it could have attained, for although I could not agree that it was flavourless, yet there were many others that I frankly confess I should have thought superior. However,

it is an encouragement for us little folks who "swim near shore" to go on our way and be glad that we can cultivate it with but little trouble, for I have cut some excellent fruit of it of fair size, which have been grown in a common pit where I wintered my Auriculas, filled up afterwards with manure and planted. The Melons set themselves, and beyond the mere thinning-out have been grown really without any trouble whatever.—D., Deal.

### VAGARIES OF FRUITS.

EVERYBODY seems to agree in pronouncing Devonshire Quarrenden Apple a good dessert kind. This brings to my mind that I can point out several fruits of excellent character which for some reason do not maintain that character when grown here, and I have no doubt that if people would record their own experiences freely, untainted by anything they have heard or read, we should hear of many more peculiarities in different varieties of fruits, brought out by local circumstances, than are at present dreamed of. But it is a difficult matter to go in the face of all good authorities as to the merits of different fruits—one is apt to shrink from it, and try to persuade himself that he must be mistaken. I, however, think too much modesty in this respect is extremely hurtful, and that information gained from careful study and experience, however it may differ from generally received opinions, is always worth recording; and although we may be told that the fault is in the culture rather than in the fruits, we can retort that that culture suits some varieties exceedingly well. Now, Devonshire Quarrenden with me is perfectly useless; it is not eatable, and never softens till it decays. I have had two trees of it in different situations; one is already destroyed, and the other is condemned.

Another very beautiful Apple, a perfect model for a dessert fruit, Court Pendu Plat, comes good enough to look at; the shape and colour are magnificent, but it will not ripen; it keeps till spring, and then shrivels and becomes perfectly dry and tough. With regard to this variety I am seconded by my friend Mr. Ellam of Bodorgan Gardens, Anglesey, an excellent fruit cultivator, who tells me that Court Pendu Plat is no use with him, but that previous to going there he had always known it as one of the very best of Apples.

The two instances I have mentioned are exceptions, but there are some Apples which bear good characters without deserving them at all. What, for instance, is the use of Emperor Alexander, except to look at? and even then its shape is not handsome. Of summer dessert Apples I find Irish Peach, Oslin, and Kerry Pippin among the best. Amongst winter cooking Apples Blenheim Orange is, I believe, generally considered the best flavoured, but I have a bright-coloured very handsome Apple which Mr. Cramb of Tortworth pronounces Brabant Bellefleur, and it by far excels Blenheim Orange in both appearance and flavour when cooked, good as that variety is.

Of Pears, two of the best standard varieties, Louise Bonne of Jersey and Joséphine de Malines, I have never yet had first-rate, although late and early gathering and different kinds of treatment have been tried. There is always a peculiar bitterness about them. Marie Louise I succeeded with last year for the first time in having it first-rate by leaving it on the tree till the end of October. Jaminette, Hacon's Incomparable, Duchesse d'Angoulême, and Beurré Diel are always coarse and insipid. Among the best are Jargonelle, Williams' Bon Chrétien, Beurré Superfin, Fondante d'Automne, Beurré d'Amanlis, Suffolk Thorn, Doyenné du Comice, Van Mons Léon Leclerc, Thompson's, Beurré Hardy, Monarch, and Glou Morceau. The last-named requires a wall, and Van Mons Léon Leclerc is very fine from a south wall; the others are probably all best as standards in this part of the country.

Amongst Peaches, Early Ascot is not early, nor is Dr. Hogg; both of them ripen later than Grosse Mignonne and not much before Bellegarde. Noblesse is not sufficiently hardy, nor is Belle Bance. Grosse Mignonne is certainly not so hardy as some varieties, but it is the best Peach in its season. I cannot do without it. The following are among the best:—Early Beatrice, Early Louise, Frogmore Golden, Grosse Mignonne, Bellegarde, Barrington, and Walburton Admirable. They are named in the order of ripening, and last from the end of July to the end of October; but there is a gap between Early Louise and Frogmore Golden which I hope to see filled by some of the newer kinds I have on trial.

There are many good midseason Peaches coming in at the

same time as Grosse Mignonne, Bellegarde, and Barrington, but these three form a perfect succession; they are hard to beat for quality, and the last two are especially hardy. All that I have tried of Mr. Rivers' early Peaches have good constitutions, and late kinds in general have the same good quality, the bad constitutions being fortunately more amongst the midseason fruits, and, as there is an abundance of midseason kinds there is no excuse for growing the worst. Chancellor and Prince of Wales are two very fine Peaches, coming in at the same time as Barrington, and promise to be very formidable rivals to that old favourite.

I have two Peach walls. The trees on one are trained in the ordinary way, the shoots being tacked-in as they become long enough; on the other wall the trees are a sort of compound cordons, where the shoots are kept constantly pinched back, and the difference in colour on the two walls is very remarkable, those on the pinched-back trees being coloured by far the best, although great care has been taken on both walls to prevent the fruit being shaded by foliage. A gentleman wrote a few weeks ago that he did not like too much colour, but preferred Peaches with just a blush on one side. I am obliged to confess that I do not object to see them blush all round.

The soil here is heavy, resting on clay, and the atmosphere is comparatively humid. Peach borders, of course, are artificially made and well drained.—WM. TAYLOR, Longleat.

### CRYSTAL PALACE AUTUMN SHOW.

THIS Show commenced on the 21st inst., and closed on the 23rd. It was very different in character to other great shows which have been held in the same place, where we have seen the tables groan under the weight of splendid produce of the most renowned cultivators. This year the dishes were thinly placed, so as to cover as well as possible the space allotted to the Exhibition. The Show—although fruit creditable to the growers was staged—was for "the Palace" a small show. The prizes were small, and the length of time of the Exhibition great. For once the Company have aimed at too much by offering too little. The prizes were not worth cutting and staging for—that is, not worth the risk of injury to large collections of valuable fruit. We know that some exhibitors did not stage their best fruit, but "cut according to the cloth," the same as gardeners, in common with other mortals, are apt to do. They had in mind, too, the October Show at the Aquarium; and for this Show, where the prizes were on a liberal scale, they kept their best fruit in reserve, not knowing at the moment of preparing for the Palace that the Aquarium Show had collapsed.

COLLECTIONS.—A silent yet significant comment on the "short-comings" of the Crystal Palace schedule is the fact that for the four prizes offered for a collection of ten dishes of fruit not one exhibitor was forthcoming. The class for a collection of six dishes, in which prizes of £3, £2, and £1 were offered, brought forward nine competitors, Mr. Neighbour, gardener to G. Wythes, Esq., Bickley Park, securing the first place with fruit of creditable table quality. The collection embraced good Black Hamburgh Grapes, and Muscats small but of excellent quality; a Handsome Golden Perfection Melon, Pine Apple Nectarines, Violette Hâtive Peaches, and White Magnum Bonum Plums. Mr. Bones, gardener to D. McIntosh, Esq., Havering Park, Romford, was placed second for large but not highly-finished Grapes, Read's Scarlet-flesh Melon, Bellegarde Peaches, Williams' Bon Chrétien Pears, and Morello Cherries. The third prize was awarded to Mr. Burnett, gardener to Mrs. Hope, The Deepdene, Dorking, for a collection including good Muscat and fair Black Hamburgh Grapes, an excellent dish of Early Crawford Peaches, a good Melon, Victoria Nectarines (not quite ripe), and Jefferson's Plums. We noticed in the other collections good Pine Apple Nectarines from Mr. Bristow, gardener to G. Campbell, Esq., Wood Hall, Dulwich; very fine Late Admirable Peaches and Pond's Seedling Plums from Mr. Fanning, gardener to Madame Digby, The Convents Road, Roehampton; good Barrington Peaches, Golden Drop Plums, and Williams' Bon Chrétien Pears from Mr. Taylor, gardener to J. Johnston, Esq., Hampstead Heath; and capital Muscat of Alexandria Grapes (full and finely finished), and a superior dish of Coe's Golden Drop Plums from Mr. Halliday, gardener to J. Morris, Esq., Castle Hill, Bletchingley.

PINE APPLES.—In the two classes twelve fruits were staged; some of them being very good, and none unworthy of the growers. For the best Queen, that capital Pine-grower Mr. Bond, The Beeches, Weybridge, was easily first with a handsome and well-proportioned fruit weighing 6 lbs. 4 ozs. It was only just ripe, but well deserved its place. Mr. Akehurst, gardener to S. Ope-stake, Esq., The Grove, Kentish Town, was second with a perfectly ripe and well-finished fruit weighing 4½ lbs.; and Mr. Coulter, gardener to J. Baker, Esq., Haydon Hall, Eastcott, third for an equally well-finished fruit, but about a quarter of a pound lighter than Mr. Akehurst's. The Queens varied greatly

in character, one—shown in the class for “Any other variety,” named Lemon Queen, from Mr. Harris, gardener to C. L. Norman, Esq., Oakley, Bromley—being exceedingly clear. In this class Mr. Ward, gardener to T. N. Miller, Esq., Bishop Stortford, had the first place with a remarkably plump and fine Charlotte Rothschild; Mr. Plummer, gardener to R. Thornton, Esq., Canon Hill Park, Merton, being second with a good Smooth Cayenne; and Mr. Toomer, gardener to W. Knowles, Esq., Streatham, third for “Abacachi” Queen, a tall conical fruit but not perfectly ripe.

**GRAPES.**—For three bunches of Black Hamburgs there were ten competitors, Mr. Cooper, gardener to M. Yeatman, Esq., Shawfield, Bromley, winning with medium-sized, compact, well-filled, and highly finished bunches, having, however, rather small berries. Mr. Crane, gardener to Mrs. Green, Logshill, Chislehurst, was placed second with large but rather loose bunches and very fine berries, but deficient in colour; and Mr. Goldsmith, gardener to P. C. Hardinge, Esq., Hallenden, Tonbridge, being third with small bunches of admirable finish and quality. In the judging of this class the first prize was awarded for quality, the second for size, and the third again for quality—a system of judging not a little bewildering to exhibitors. In this class most of the Grapes were rubbed, some of them very much so, which imparted to them a roughness which considerably marred their appearance.

For three bunches of Muscat of Alexandria Messrs. Lane and Son, Berkhamstead, were far ahead of their six competitors with very large, well-shaped, and perfectly ripened bunches, each weighing 5 to 6 lbs.; Mr. Pepper, gardener to G. W. Norman, Esq., Bromley Common, being second with small bunches but perfectly finished; and Mr. Cole, The Grove Vineyard, Feltham, third with large and full bunches, but defective in colour and finish.

In the class for three bunches of any white variety except Muscat of Alexandria, Mr. Toomer had the first place with excellently finished bunches of Foster's White Seedling; Messrs. Lane & Son being second with large but rather unshapely bunches of Buckland Sweetwater, and Mr. Oliver Goldsmith, Polesden Lacey, Dorking, third with large bunches but small berries of Trebbiano.

For three bunches of black Grapes other than Black Hamburg Messrs. Lane & Son were first with excellent Alicantes; Mr. Earp, gardener to J. S. Sellon, Esq., being second with smaller yet highly finished bunches of the same variety; and Mr. Clarke, gardener to J. Rains, Esq., Clapham Common, third for small yet perfectly ripened bunches also Alicantes. In this class three excellent bunches of Lady Downe's Seedling were exhibited by Mr. Hall, gardener to W. Stevens, Esq., Springfield, Tulse Hill, worthy of honourable mention by the regularity of the berries and the spotless condition in which they were set up. They were not quite ripe.

For the heaviest bunches of Grapes Mr. Bones, gardener to D. McIntosh, Esq., was first with Black Hamburg, weighing 4½ lbs.; and Mr. Crane second with the same variety, weighing 2½ lbs. One of these bunches was over-ripe, and the other green. The money may be regarded as thrown away, but there was not much to mourn over. In the Grape classes several of the bunches were small, while others were of fairly good quality, and more than worthy of the prizes of £1 10s., £1, and 15s. which were provided for them. For Vines in pots Messrs. Lane and Sons had no competitors. They exhibited Black Alicante, with fourteen bunches averaging a pound weight each and well coloured, and Foster's White Seedling very good.

**PEACHES AND NECTARINES.**—Twenty-five dishes were staged, Mr. Burnett, The Deepdene, securing first honours with capital fruit of Early Crawford; Mr. Goldsmith, Hollanden, being second with medium-sized handsome fruit of Reine des Verges; and Mr. Penfold, gardener to Rev. Canon Bridges, Beddington, third, for an excellent dish of Violette Hâtive. An extra first prize was worthily awarded to Mr. Holliday, gardener to J. Norris, Esq., Castle Hill, Bletchingley, for extra large fruit of Salwey. Late Admiral was well exhibited by Mr. Austin, gardener to Miss Green, Dudley House, Clapham Common, and Alexandra Noblesse by Mr. Holder, Wilmington Lodge. Mr. Tillery, Welbeck, exhibited Grosse Mignonne, very fine but much too ripe, and a good dish of Walburton Admirable, named Noblesse, came from Mr. Brown, Clock House, Beckenham.

Of Nectarines, twenty-two dishes were staged, Mr. Neighbour winning with Pine Apple of fair size and highly coloured; Mr. Penfold being second with Downton; and Mr. Jordan, gardener to J. Boustead, Esq., Wimbledon, third with Elruge. Mr. Brown, Beckenham; Mr. Tillery, and Mr. Snelling, Stoke-on-Trent, exhibited well. Except the fruit of the exhibitors named the Nectarines were small.

**PLUMS.**—These were very good, nineteen competing in the class for a single dish, Mr. Neighbour winning with Coe's Golden Drop, fine fruit but not ripe. Mr. Coulter, gardener to J. Baker, Esq., Haydon Hill, was second with an excellent dish of Transparent Gage; and Mr. Dean, gardener to G. N. L. Gower, Esq., Titsey Place, Limsfield, third for very fine

Jefferson's. Both these dishes were much superior in quality to the first-prize fruit. For three dishes there were ten competitors. Mr. Holder, gardener to J. Bailston, Esq., Springfield, Maidstone, was first with Coe's Golden Drop, Jefferson's, and Green Gage, all superior; Mr. Dean, Limsfield, being second with the same varieties, substituting Kirke's for Green Gage; Mr. Penfold was third with Diamond, Jefferson, and Cox's Emporer; and Mr. Oliver Goldsmith fourth, his best dish being Goliah.

**MELONS, FIGS, AND CHERRIES.**—In the class for Green-fleshed Melons fourteen fruits were staged, none of them being particularly handsome nor excellent. Mr. Oliver Goldsmith, Polesden Lacey, Dorking, was first with “Hybrid Green-flesh” (Golden Perfection). Mr. Ford, gardener to J. Megaw, Esq., Windermere House, Norwood, second with an unattractive oval-shaped fruit of Heckfield Hybrid; and Mr. Penfold third with Conqueror, a handsome oval-shaped white-fleshed variety, very juicy and sweet, but destitute of aroma. In the Scarlet-flesh class fifteen fruits were exhibited. Mr. Holliday, Castle Hill, winning with a very superior fruit of Scarlet Gem; Mr. Glasscock, gardener to J. Banbury, Esq., Shirley House, Croydon, being second with fine fruit of Hutley's Hybrid; and Mr. Penfold third with Eclipse, a handsomely-netted, thin-skinned, and excellent fruit. An extra prize was awarded to Mr. Oliver Goldsmith. The Scarlet-fleshed were on the whole superior to the Green-fleshed fruits.

Only four dishes of Figs were staged, Mr. Chisholm, Boughton Place, Maidstone, winning with fine unnamed fruit resembling Brunswick; Mr. Webb, Calcot, Reading, being second with Brown Turkey; and Mr. Oliver Goldsmith third with the same variety. A very fine dish of Brunswick arrived too late for competition from Mr. Miller, Southdown Nursery, Shoreham.

Only four dishes of Morello Cherries were staged, the prizes going to Mr. Jones, The Gardens, Elvetham, Winchfield; Mr. Taylor, gardener to J. Johnston, Esq.; and Mr. Harris, Bromley, in the order named for excellent dishes. Mr. Jones' fruit being especially superior.

**APPLES AND PEARS.**—These were not nearly so numerous as at the Exhibition of last year, yet many of the fruits, of Apples especially, were extremely fine. In the class for four dishes of dessert Apples Mr. Webb, Calcot, Reading, was placed first with Cox's Orange Pippin, Red Astrachan, Ribston Pippin, and Cornish Gilliflower, all of which were large and fine. Mr. W. Fanning, gardener to Madame Digby, was placed second with Autumn Pearmain, King of the Pippins, Ribston Pippin, and Margil; and Mr. Penfold third with Cellini, Fearn's Pippin, King of the Pippins, and Ribston Pippin, both the collections being extremely good. Handsome dishes of Early Julien, Jefferson, a variety stated by the exhibitor to have been raised at Frogmore, but much resembling Duchess of Oldenburgh; Cox's Orange Pippin, and extremely highly coloured Red Astrachans came from Mr. Holder, Maidstone.

In the class for three dishes of kitchen Apples there were fifteen competitors, and some fine collections were staged. Mr. Brush, gardener to Lady Hume Campbell, High Grove, Pinner, was awarded the first prize for a grand dish of Hawick King, a variety raised by Messrs. Downie, Laird, & Laing, and somewhat resembling superior specimens of Alfriston; Hollandbury very highly coloured, and rather small Damelow's Seedling. Mr. Murrell, Coleman's Lodge, Prittlewell, was second with Hawthornden, Beauty of Kent, and Warner's King, all superior; and Mr. Webb, Calcot, third with Red Astrachan fine but light in colour, Fillbasket, and a splendid dish of Blenheim Orange. A fourth prize was awarded to Mr. Penfold.

**PEARS.**—For three dishes of dessert kinds Mr. Holder, gardener to W. Balston, Esq., was placed first with Williams' Bon Chrétien, Gratioli, and “Theodore Maré” (Beurré Superfin), all fine. Mr. Penfold was second with Beurré d'Amanlis, Souvenir du Congrès, and Williams' Bon Chrétien; and Mr. Bristow, gardener to G. Campbell, Esq., Wood Hall, Dulwich, third with Louise Bonne of Jersey, Beurré d'Amanlis, and Beurré Hardy, a fourth prize being awarded to Mr. Neighbour. The fruit to which the prizes were awarded was very good and in excellent dessert order, but many other dishes were totally unripe. In the class for one dish of Pears for weight Mr. Jordan, gardener to J. Boustead, Esq., won with Calebasse Grosse, the nine fruits weighing 7 lbs. 2 ozs.; Mr. Oliver Goldsmith being second with Catillac, and Mr. George Goldsmith, gardener to P. C. Hardwick, Esq., Hollanden, Tunbridge, third with White Doyenné.

**CUT FLOWERS.**—There was very little competition in these classes. For forty show Dahlias the competition lay between Mr. Charles Turner, the Royal Nurseries, Slough, and Mr. Coppin, the Rose Nursery, Shirley. Mr. Turner was far ahead, nearly all the blooms being remarkably fine. The best of the new varieties were Barmid, white tipped purplish crimson; Christopher Ridley, scarlet; Mrs. Purvis, amber tipped with white, new in colour and of great substance; Captain Webb, buff, fine form; Royal Purple, smooth and fine; Samuel Plum-

soll, rich purple; and of the older sorts Acme of Perfection, Arbitrator, Cremorne, Flag of Truce, George Goodhall, Henry Walton, James Cocker, John Dunnington, John Standish, Leah, Mrs. Boston, Mrs. Henshaw, Ovid, Charles Leicester, Princess, and Red Rover. Mr. Coppin's blooms were smaller, yet his collection contained some good flowers. The same exhibitors were placed in the same order for twenty-four blooms of fancy Dahlias, Mr. Turner being again considerably in advance. The best twelve blooms in this class were Mrs. Standish (new), amber, the petals being tipped and striped with white, a full flower of great substance; Dolly Varden, Egyptian Prince, Grand Sultan, Laura Haslam, Miss Lilly Large, Mrs. Saunders, Pauline, Pluto, Henry Glascock, Peacock, and John Bennett. In the amateurs' class for twelve show Dahlias Mr. George Smith, Hedge Lane, Edmonton, was placed first, and Mr. Penfold, gardener to Canon Bridges, second; and for twelve fancy Dahlias the first prize was withheld, the second being awarded to Mr. Penfold.

Asters were not numerous, nor, except those from Mr. Betteridge, Aster Nursery, Chipping Norton, superior. For twenty-four quilled varieties Mr. Betteridge was first; Mr. Morgan, gardener to Major Scott, Wray Park, Reigate, second; and Mr. Brown, gardener, Clock House, Beckenham, third. For twenty-four tasselled varieties Mr. Betteridge and Mr. Morgan were placed first and second respectively; and Mr. Osborne, gardener, Conduit Lodge, Blackheath, third. Gladioluses were well and extensively exhibited by Messrs. Kelway & Son, Langport, and Messrs. Robertson & Galloway, Glasgow. As a rule the English-grown spikes were broader and fuller than the spikes from Scotland, which were tall and stately. The moist climate of Scotland appears to be more favourable for perfecting the Gladiolus than the drier districts of the south. Some of the most striking varieties are specially noticed by an "expert" in these flowers.

MISCELLANEOUS.—In this class there was a considerable number of exhibits, and many extra prizes were awarded—namely, to Mr. Turner for a collection of Dahlias and Roses; to Messrs. Paul & Son, the Old Nurseries, Cheshunt, for a collection of Roses and Apples; to Messrs. W. Paul & Son, Waltham Cross, for Roses. The Roses from these exhibitors were numerous, and for the season excellent, Marie Van Houtte was especially lovely, as also was Madame Willermoz, while such sorts as La France, Maréchal Niel, Général Jacqueminot, and other popular varieties were in admirable condition. From the extensive collection of bouquet Dahlias staged by Mr. Turner we noted as being especially attractive—Triumph, scarlet; John Sandy, orange; Vesta, white, charming; Louis Rodani, pale lilac; Dwarf Queen, crimson, purple, and white; Vesuvius, soft scarlet, fine; Red Gauntlet, Yellow Pet, and Flora Macdonald, primrose. Either for distant effect or close examination these miniature and floriferous varieties are recommended. A prize was awarded to Mr. George Rawlings, Old Church, Romford, for an admirable collection of Dahlias, amongst which as being especially worthy of mention, we noticed the Earl of Beaconsfield, maroon purple; Herbert Turner, nearly white, a splendid flower; Willie Eckford, crimson purple of great depth, and excellent; Caroline Tasker, lilac and white, charming; Queen, white and purplish lilac, fine; Acme of Perfection, yellow; Nancy, maroon, tipped white; Memorial, James Service, &c. Messrs. Kelway and Son had an extra prize for a fine collection of Gladioli; Mr. Foreman, gardener to T. Shepherd, Esq., Laurie Park Gardens, Sydenham, for Cockcombs; Mr. Davy, gardener to B. Drew, Esq., Streatham, for Vine in pot and Pine Apples; Mr. Ford, gardener to J. Megaw, Esq., Windermere House, Norwood, for a pair of excellent plants of Clerodendron Thomsoniæ; Mr. Horton, gardener to C. A. R. Hoare, Esq., Kilsey Manor, Beckenham, for three Ferns, one of which, Adiantum farleyense, has never been exhibited in finer condition, the plant being 4 feet through, and the fronds of the richest green; Davallia Mooreana was also very fine. An extra prize was also awarded to Mr. Webb, Calcot, for a collection of twenty-four varieties of Nuts. A few of the finest of these were Improved Cosford, Duke of Edinburgh, Marquis of Lorne, Princess Royal, and the Bullet Cob. This collection attracted considerable attention. Mr. Brown, Beddington, exhibited a handsome dish of Carter's Green Gage Tomato, and Mr. Neighbour excellent Red and White Currants, the fruit being very large and perfectly fresh.

First-class certificates were awarded to Mr. Betteridge for new quilled Asters of remarkable quality, and in colours alike charming and distinct. Blushing Bride, white and pink, is a splendid variety; Princess Royal, pink, is exceedingly full and fine; as also are Princess Alice and Bridegroom. Tom Thumb Oxonian, a liliuputian variety, white and violet, was also certificated. These are the last and best of Mr. Betteridge's productions, and if growers will perfect these varieties as they were here exhibited they will add a charm to their gardens which they did not possess before. Mr. Eckford, nurseryman, Swindon, had a similar award for new Verbenas Monarch, Queen Victoria, and Star of England; and Mr. Turner, Slough, for

Dahlias Christopher Ridley and Edith Turner. The former is a grand scarlet flower, exceedingly full, and of great substance—a massive yet refined bloom, and a great acquisition. The latter is a flower of fine quality; it is full and symmetrical, the colours being pure white tipped with yellow.

Prizes were also given for cottagers' vegetables, and highly creditable produce was staged. The Onions were very large, Potatoes somewhat coarse, except Snowflake. Carrots, Celery, Vegetable Marrows, Cucumbers, &c., all being very well exhibited.

The Exhibition was arranged in the eastern transept, the central table being furnished by Mr. Thompson with excellently grown table plants, the Dahlias and Asters being arranged around the hippodrome in front of the orchestra, the centre being occupied with Palms and other ornamental-foliaged plants. The fruit, &c., was arranged by Mr. Wilson, who certainly placed it to the best advantage. The awards were expeditiously made and placed on the exhibits; in a word, the Palace is admirably adapted for a fruit show, and the officials are experienced and competent; but shows worthy of the name and fame of the building cannot be expected unless cultivators are treated in a considerate and liberal manner by the Directors.

ALTHOUGH the anticipations of "A FORMER EXHIBITOR" proved correct, and the most meagre show of fruit and flowers that ever was held in the Crystal Palace was the result of the most niggardly schedule the Company ever sent forth, all those leading exhibitors of fruit who used to meet there in friendly rivalry being conspicuous by their absence, there was one point in the Exhibition which attracted great attention—that where the Gladioli were staged, and especially the stand which was exhibited by Mr. Galloway, of the firm of Robertson and Galloway of Helensburgh and Glasgow, N.B. I have attended, I believe, every metropolitan exhibition where this noble autumnal flower has been exhibited ever since it came to the front rank, and I have no hesitation in saying that such a stand has never been put up at any of them before. Mr. Galloway has now fairly earned the title of the champion exhibitor, having beaten Mr. Kelway on three separate occasions—last year at South Kensington, and this year at Dundee, and now he comes up with a stand so fine that Mr. Kelway declines the contest. He may, however, rest satisfied with his fame and with the achievements which still, I have no doubt, await him as a raiser of fine varieties. Lord Hawke was there also, and at another time his stand might have challenged much attention, but in the presence of such an exhibit as Mr. Galloway's it fell into the background. Nor must I omit a most meritorious stand exhibited by another Scotchman as an amateur, Mr. Campbell of Gourrock; he has evidently been to a good school, and is learning to show in the style and finish of Mr. Galloway.

Mr. Galloway's stand was composed of the following varieties, of which it will be seen nearly all are of French origin:—Le Phare, a magnificent bloom with fourteen open flowers on it; Lacépède, Octavie, Sappho, Reine Blanche, De Mirbel, Horace Vernet, Leda, Lamarck, Racine, La France, Fulton, Phidias, Rosita, Meyerbeer, Orphée, Marquis of Lothian, Legouvé, Madame Desportes, La Favourite, Adolphe Brogniart, Psyche, Virgile, Meg Merrilees, Rosa Bonheur, Celestine, Schiller, L'Unique Violet, John Waterer, Sirène, Isabella, and Ondine, very grand. When I say that some of these were astonishing, I only re-echo the opinions expressed by every Gladiolus grower who saw them. Le Phare we have not thought much of in the south, but here it was simply magnificent. Octavie I could never grow straight, it always went about in all directions; here it was very fine. But it is useless to single out where all was good. A word, however, must be said for Marquis of Lothian, for which a first-class certificate was awarded. It was raised by Mr. Codling of Morpeth, and is a grand flower deserving of the distinction it has obtained. In colour it approaches Lacépède, being of a rosy lilac hue; the lower segments being creamy towards the base, with a crimson feather. The flower is well shaped, and the spike compact and long, far superior to many of the French novelties of this year, which as a collection fall short of their usual excellence. Mr. Campbell's twelve comprised Orphée, very fine; Dido, L'Unique Violet, Psyche, Robert Fortune, Sirène, Le Phare, Rosa Bonheur, Canova, and De Mirbel; while amongst Lord Hawke's flowers the most conspicuous were Lacépède, Hercule, fine; Cœur de Lion, good colour, but not sufficient length of spike; Rosita, Amaranthe, beautiful soft colour; Eugène Scribe, Nestor, Christophe Colombe, a fine new sort; Virgalis, Fiametta, Murillo, Ondine, Astrée, and Cybele. Mr. Kelway exhibited a fine stand containing his own seedlings, some of which were remarkably fine, especially Duchess of Edinburgh, which has on previous occasions obtained first-class certificates.

And this is the only occasion in which the Gladiolus has been exhibited in London this year! A melancholy proof of the decline in the interest taken in florists' flowers. A talk was held at the Judges' dinner of holding a great international fruit and flower show next year at the Palace on the scale of the

Scotch shows, and it is to be hoped that it may be successful.—D., *Deal*.

### CAPE AMARYLLIDS.

*BRUNSVIGIA* (properly *Amaryllis*) *Josephina*, A. *Belladonna*, *Brunsvigia multiflora*, the *Guernsey Lilies* (*Nerine*), and the section of *Hæmanthus* represented by the old *H. coccineus*, require the same treatment with but slight variation.

All the above South African bulbs agree in flowering about September in our English climate. Soon after flowering the leaves push and continue growing during the whole winter, dying off finally in the month of May. From this time till September again the plants may be set out of doors in a warm aspect, upon a hard bottom to keep out worms, and be left exposed to sun, wind, and rain as the case may be. They will all keep perfectly healthy under this treatment, but as they differ in hardiness the following difference in management must be observed: The *Belladonna Lily* and *Nerine flexuosa* will succeed simply planted out under a warm south wall even in our midland counties, also in favoured spots *Nerine Fothergillii*, but infinitely better with a glass light over them.

*Amaryllis Josephina*, however, *Brunsvigia multiflora*, and the *Hæmanthi* must be wintered in the greenhouse. A. *Josephina* and B. *multiflora* are greatly benefited by a little bottom heat about a month before the flowering period, say during August, when they may be either plunged in a Melon bed, or placed upon a warm fire or other warm berth indoors. This is not necessary for *Hæmanthus*. When their buds push the plants may be taken into the greenhouse, where they must remain till May. During the leading season they will require plentiful supplies of water. In fine seasons the *Hæmanthi* put on their most glorious colours out of doors. A huge mass of *Hæmanthus coccineus* with twenty-two heads is now in flower at Walton, and positively dazzles the eyes with its blood-red blossoms in the sunshine.

I hope I have been sufficiently explicit in endeavouring to give the real treatment of these plants, which is very little known though so simple, and I shall be happy to give any additional information if requested.—R. TREVOR CLARKE.

### KEEPING GRAPES IN AUTUMN.

Most late Grapes will now be approaching maturity. Until they are quite ripe, or nearly so, damp or decay are seldom troublesome; but when they are thoroughly ripe it is a difficult matter with many to prevent them from decaying throughout October or November. These are the two months when it is generally found that Grapes are most subject to damp and decay. In December and further on the malady is, as a rule, greatly modified, and I have known instances where the greater part of many of the bunches rotted during October, and especially November, and after that time not a single berry decayed. I do not think this was owing to any atmospheric change, but the fruit appears to become tougher in the skin after it has hung for six weeks or two months. It is thus evident that if Grapes can be kept in a perfect state of preservation for the next two months their keeping after that time will be an easy matter. I will only, therefore, note the requirements of Grapes during October or November.

Grapes are often cut and preserved with their stalks in bottles of water throughout the winter, but this plan is seldom practised until well nigh the new year, and therefore further reference to it will not form part of these notes. Lady Downe's, although very thick in the skin, is one which generally suffers very much from damp; I have found it worse than Black Alicante, or even Gros Colman, although the latter is very thin in the skin. Grapes which are well thinned do not generally decay so much as those in firm clusters; and as a partial guard against damping, all Grapes that are to hang over October and November should be more thinned-out than those which are to be cut before that time.

For the next two months the atmosphere of vineries in which Grapes are hanging cannot be kept too dry, but at the same time a warm atmosphere must be avoided. When a vinery is always kept at a roasting heat, as many are with the idea of preventing damp from rising, the fruit very soon begins to shrivel; and although the fruit is not lost through this taking place, it loses much of its value. The vinery should always be kept as dry as possible without the aid of fire heat, and when it is applied care should be taken that the top ventilators are open sufficiently to allow the moisture as it rises to escape freely.

Many people err in firing strongly at night when the venti-

lators are closed, and in the morning the dew may often be rubbed off the fruit. This is a fertile source of decay. When it is necessary to apply fire heat, which it sometimes is, especially in damp weather, the fire should be lighted on a fine day when both top and bottom ventilators can be opened wide to admit of the house being thoroughly dried; and on dull damp days give no fire heat, but keep the ventilators shut and the atmosphere as quiet as possible, and very little damping will then occur. In frosty weather when a little fire has to be kept up the ventilators should be constantly left slightly open, that the damp which rises at such times may escape and not rest on or about the fruit, and then the temperature should never exceed 40° at night or 45° during the day. As the days are generally fine when the nights are frosty no fire heat should be used during the day, and while the sun shines on the vinery the ventilators should always be opened much wider than at night. The temperature must not be kept high at one time and low at another, as this is also productive of decay.

During the time all these precautions are being taken the bunches should always be looked over twice or three times a week, and any berry which shows the slightest sign of decay must be at once removed, as one rotten berry soon affects the one next to it, and if not taken in time half of the bunch may be lost in a very short time. In houses full of plants and where Grapes are hanging it is no easy matter to keep the atmosphere dry; but careful airing and firing, as above indicated, are the only and best means of proceeding under such circumstances.—VITIS.

### THE PARKS OF LONDON.

#### REGENT'S PARK.

REGENT'S PARK was commenced arranging in 1810 from plans suggested by Mr. W. Fordyce, who at the time was surveyor of the national woods and forests.

The south side of the Regent's Park is about half a mile in length, and parallel to the New Road, which is to the south of it. The east side, nearly at right angles with the south side, extends northward to Gloucester Gate, a distance of almost three-quarters of a mile. The west side, forming an oblique angle with the south side, extends in a direction west of north to Hanover Gate, a distance of half a mile. The northern terminations of the east and west sides are connected by an irregular curve nearly coinciding with the sweep of the Regent's Canal, which passes along and within the northern boundary of the park. A sheet of water extends from Hanover Gate in a south-east direction, parallel to the west side of the park, and, curving round at a south-west angle, continues in a direction parallel to the south side to about the middle of it. Opposite the middle of the west side, an arm of this sheet of water extends at right angles to the very centre of the park. The bottom of the valley, through which Tyburn rivulet flowed in days of old, stretches from its termination up to Primrose Hill, which is nearly due north of it. Nearly two-thirds of the park, forming an oblong parallelogram, slope down on the eastern side of the valley to the former channel of the stream, and the north-east and south arms of the artificial lake which is formed by its collected waters; and which resemble, to use a simile more accurate than dignified, the arrangement of the three legs on an Isle of Man halfpenny. Within the horns of the crescent formed by its north-east and south arms is the Ring, the interior of which is occupied by the Garden of the Botanical Society. On the eastern slope, at the north end of the park, is the Garden of the Zoological Society. On the east side of the park, a little south of Gloucester Gate, are the enclosed villa and grounds of the late Sir Henry Taylor; on the west side, a little north of Hanover Gate, those of the Marquis of Hertford.

Regent's Park is thought by some people to rank as the first of our metropolitan parks. It is at any rate the largest, covering as it does about 470 acres, and the centre is to a great extent an open green plain, free almost from trees. It is set apart for pedestrians only. Vehicles are kept on the outskirts, where there is as good a road as the lovers of equestrianism can desire. This centre is in many respects well adapted and often used for military display, policemen's drill, and a cricket ground for the people. It has a most beautiful surrounding of trees, clumps of shrubs, some fine pieces of ornamental water, with islands clothed with evergreen shrubs, and the banks with weeping trees, forming excellent cover for the waterfowl to retire into. The margin of this park is very much diversified—wood and dale, and at intervals noble

mansions and picturesque villas are scattered about, half hidden by trees and shrubs.

On the north side the Zoological Garden, with its lofty trees and picturesque buildings, has a very pleasing effect, and further back Primrose Hill. On the south are the Botanical Gardens; and on the west are rustic bridges, ornamental waters, and stately trees. On the east side the flower garden is very tastefully laid out, showing both the English and the Italian style. The English consists in an imitation of nature. This has been accomplished, for here we have an undulated surface, serpentine walks, and different-shaped clumps, containing selections of the finest kinds of flowering and evergreen trees, of which some of the more striking are also planted on the grass, and have now attained considerable size. The flower beds are simple in form, judiciously placed, and effectively planted.

The Italian garden is divided into two parts by an avenue

of Horse Chestnuts, which is said to be the finest in or near London, Bushey Park included. It is nearly a mile long. The trees are not so large nor so lofty as the trees that form the avenues at Hampton Court, but certainly they are of better form. The trunks are straight and clean, and the heads are very symmetrical. It is hardly possible to imagine any object more gorgeous than this avenue when the trees are studded with millions of pink and silver flowers. In the Italian garden the decorations are brought skilfully into harmony with the natural beauty of the flowers. Handsome vases are judiciously placed and filled with suitable plants, and form striking objects. There are also many fine Yuccas planted singly in lines and in masses, the beauty of which is striking when in flower. Their great panicles of pearly-white bell-shaped blossoms contrast with such plants as the Pampas Grass, the Palms, Conifers, variegated Hollies, and several other decorative plants. The Yuccas are permanent in character, being ornamental in

Fig. 42.—REGENT'S PARK—THE ITALIAN FLOWER GARDEN.

winter as well as in summer, and also another great advantage which they possess is the vigorous growth they make in town gardens, where many other plants fail. The same may be said of the Rhododendrons, for the London smoke seemingly has no injurious effect upon them. They are as handsome here as they would be in the country, for when properly treated at the roots the smoky atmosphere does them no harm. Standard Rhododendrons and other round-headed plants are in keeping in an Italian garden, and have a good effect when planted on the turf as they are here.

The flower beds are edged with Box, the small walks gravelled, and the outside border next to the grass has an edging of Anston's stone, which gives to the whole a neat compact appearance, then comes a broad strip of turf. On this single specimens of choice shrubs and other plants are grown, all guarded with a neat wire fence. Upright Lombardy Poplars are planted at regular distances on each side of the straight walk. The hedges are neatly clipped, the grass closely shorn, the gravel walks smooth and clean, and the flowers of low-growing kinds.

Regent's Park might rest its floral reputation on well-known and familiar favourites. Geraniums of all kinds and colours are here found in profusion, and other well-known plants glowing with colour—masses of Heliotropes that load the air with perfume. Small delicate-coloured-leaved plants are used

for edging other taller subjects, exhibiting a nicety of art. All the plants are well grown and skilfully displayed.

Mr. Iverson has charge of this flower garden, and he displays a mastery in the way in which he manages to combine the most gorgeous of bedding plants with a general assemblage of less gaudy and less formal subjects; and it is well he has for a superintendent Mr. Edwards, who has himself a keen eye for the beautiful.—N. COLE, *Kensington*.

#### NOTES ON SOME SPECIES OF ONCIDIUM.

The genus *Oncidium* is a very extensive one, and the largest number of the species are exceedingly showy and free-flowering. They are also, very nearly all of them, of easy culture, which is an important point in their favour. Some of the species are very robust in growth, requiring considerable space for their development, and are not adapted for small houses and for limited collections of select varieties, though such species as *O. sphacelatum*, *O. altissimum*, and others are very useful in mixed collections of plants, as they throw up numerous long spikes of flowers which come in useful for cutting where a large supply is wanted. The above two sorts succeed best in the plant stove.

A few sorts are well adapted for culture in cool houses, and ought to be in the most select collection of Orchids.

Fig. 43.—*ONCIDIUM CRISPUM FLAVUM*.

Foremost amongst them may be named *O. macranthum*, a noble species with large flowers like golden butterflies thinly scattered on a spike 10 or 12 feet in length. Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, has a fine plant of this species growing in the cool Orchid house, where the temperature has fallen to 35° in winter. It is suspended near the roof, and is growing in the bifurcation of a stout limb of a tree. *O. bifolium majus* is the very reverse of this sort, it can be grown in the same house suspended from the rafters in the same way, but it is a small-growing species with spikes a foot to 18 inches long, producing large bright yellow flowers marked with brown on the sepals. *O. cucullatum* and varieties of this species are also very small in growth; the flowers are beautifully marked with rose and purple, and last a long time in perfection; indeed, this is a characteristic of many of the New Grenadan Orchids, at least those of them that are brought, as this one is, from the mountain ranges 7000 or 8000 feet above the sea level. It also succeeds well in the coldest house. Nearly every Orchid fancier grows *O. Papilio* and the allied species or variety *O. Krameri*; its flowers, perched singly on the end of long slender stalks 2 or 3 feet in length, remind one of gaudy foreign butterflies with outstretched wings.

A very large proportion of *Oncidium*s succeed well in the Cattleya or Brazilian house—that is, with a night temperature of from 50° to 55° in winter and from 60° to 65° in summer, rising from 5° to 10° higher in the day. During a period of at least three months in summer no artificial heat is needed in the Cattleya house. *O. ampliatum majus* is one of the very finest of the species; it produces long branching spikes of flowers in May and June, which are of large size and produced in abundance. It is well known to frequenters of the early exhibitions in London, as it is almost indispensable in a col-

lection. Another strong point in its favour is the fact that it is very easily grown in pots half filled with clean potsherds and then a layer half an inch thick of clean fresh sphagnum moss, then a compost of tough fibrous peat, chopped sphagnum, and potsherds in equal proportions. The plants require

to be kept moderately moist when in full growth, but the resting period must be marked by a very limited supply of water—just enough to prevent the bulbs from shrivelling. It is a native of Guatemala. Then there is the rare and magnificent *O. splendendum*, which requires very similar treatment. It is very seldom seen at exhibitions, not because it is not adapted for exhibition purposes, but because it is so very rare that very few persons are in possession of the plant. I have seen it only once in flower, and that was a very fine plant exhibited by Mr. W. Denning some five or six years ago in one of the choice collections he exhibited at South Kensington. The plant had one strong spike about 2 feet long with a dozen expanded flowers of large size; the sepals and petals are dull yellow blotched and barred with purplish brown, with a very large expanded lip of a rich bright yellow. It is also from Guatemala. Another equally rare species is *Oncidium Rogersii*. It is from Brazil, but does well amongst the Cattleyas, and requires the same treatment as *O. ampliatum majus*. The finest plant in existence is that in the rich collection of Messrs. James Veitch & Sons, Royal Exotic Nursery, Chelsea; it produces a large branched spike annually in November, containing upwards of two hundred fully expanded flowers at one time. The spike is not erect like *O. splendendum*, but arches over gracefully. The flowers are of a beautiful golden colour, and are from 2 to 3 inches across the lip.

*Oncidium crispum* and the variety *flavum* are natives of the Organ Mountains. They also succeed best in the Cattleya house, but must not be grown in pots with peat and sphagnum, for such Orchids cannot bear much organic matter to come in contact with the roots. *O. crispum* succeeds best on a block. The plant ought to be fastened to this, and the base of the block should be placed in a pot, and the space between it and the sides of the pot should be filled-in with clean potsherds. The roots require water daily, but avoid watering the leaves and pseudobulbs. The flowers are of the uniform shade of a copper-coloured Indian. *O. crispum marginatum* is of the same colour as the type, but the sepals and petals are margined with bright gold, while *O. crispum flavum* is of a uniform coppery yellow with scant markings. This fine Orchid has received a first-class certificate during the present year, and the plant has attracted much notice at several exhibitions, where it has figured prominently in the collections arranged by Messrs. Veitch, and from which plant the accompanying figure was taken.—J. DOUGLAS.

### THE CULTURE OF TOMATOES.

Not many years since the Tomato (*Solanum Lycopersicum*) was only grown in a few gardens, and then in some cases only for ornament, but the rapidly increasing demand for this highly ornamental esculent has now to be part of the study of nearly every gardener, however small and meagre may be his convenience. The Tomato is highly esteemed by most owners of gardens, and also by gardeners, who usually exhibit a collection of vegetables in the early summer, when a dish of Tomatoes is found an acquisition and a very strong point in favour of the exhibitor.

Tomatoes are so esteemed by my employers that they would use them in some form every day throughout the year were they obtainable, oftentimes using them cut into slices similar to Cucumbers, and served uncooked with oil. To meet this demand it occurred to me (for want of other room) that the plants might be grown in pots on a shelf in the apex of a small house, which place I found very suitable, and the plan proved a success. This mode of culture I have practised now for several years. During January or early in February I well drain an 8-inch pot, three parts fill it with soil, and sow some seed of the Orangefield Dwarf, and plunge the pot in a common hotbed; the seed will rapidly germinate, and in a few days the plants will appear. As soon as large enough I carefully thin them out, leaving about twenty-four of the strongest; this prevents the young seedlings from being overcrowded and drawn up weakly. By sprinkling a little soil around and between them they emit roots further up the stems, and remain short and sturdy. When about 3 inches high they are found strong enough to handle safely, and are potted in 5-inch pots. I pot them as low as possible, and replace them in the hotbed again. As soon as well rooted they are shifted into 9-inch pots, using a compost of turfy loam, and it is astonishing, if well fed, what a large quantity of excellent fruit of this variety can be produced by plants in pots of this size. After shifting them to their fruiting pots they are placed on a shelf near the

glass in a Cucumber pit, vinery, or even a warm greenhouse (my only convenience at that time was a warm greenhouse), and are kept close for a few days. After the roots have begun to move freely the plants have plenty of air and all the sun they can possibly have. Many of them soon require staking, and by the time these pots are full of roots the plants begin to show flower. As soon as two or three clusters of blooms show I nip off the points of the main stem, and remove all subsequent growths as they appear. When the fruit is large enough to discern their shape they are thinned out with a pair of scissors, removing all which are faulty or corrugated, carefully retaining such as are likely to become large, smooth, and handsome fruit.

The plants are grown on as fast as possible, taking care to keep them stout and stocky and well supplied with clear and liquid manure water. Occasional doses of soot water are very beneficial to them—in fact Tomatoes are very gross feeders, and are among the most thirsty plants in cultivation. When exposed to the full influence of the sun on a shelf, turf sods—such as the edgings of turf from the sides of walks, and short manure placed around and between the pots—prevent the moisture from rapidly drying out of the pots, and the roots ramify into the rich material, and from it the plants obtain much nourishment. As the fruit increases in size it is found necessary to support some of the clusters with bast suspended from the tops of the stakes.

The Orangefield Dwarf grown in the above way and kept close to the glass will carry a good crop of fruit, and the plants will not be more than 18 or 20 inches in height from the top of the pots. It is only on account of its dwarf habit that I advocate the growing of this prolific variety, for since the introduction of Hathaway's Excelsior it has in several points superseded the above, more especially for its earliness and smoothness, it being the very perfection of shape, and if planted out in any convenient place under glass and kept well stopped it will produce abundance of handsome fruit. I have found the fruit of this variety if subjected to a close atmosphere liable to crack, which is not the case with the Orangefield.

The Tomato is readily increased by striking cuttings. A few plants kept through the winter will furnish plenty of cuttings, and these if rooted will become fruiting plants sooner than others which have been raised from seed; but in my opinion the success of fruiting Tomatoes early depends in a great measure on the stopping of the plants.

I have planted them out on a south border after carrying a crop of fruit in pots, and trained and stopped them in a bush-like form to stakes, and they have carried the second crop. Whether planted against walls or in an open piece of ground attention must be paid to stopping and watering, and every means rendered to enable the fruit to ripen as soon as possible before the chilly nights and early autumn frosts set in. All such as are not ripe must be gathered and placed under cover where they will ripen. In cold wet seasons they are liable to a disease similar to the disease in Potatoes.

With regard to the announcement that "the introduction of Tomatoes into the vinery will prevent wasps eating Grapes," I have to say that I have tried the plan during the past few weeks, and have found it absolutely useless for the purpose recommended.

The variety recently introduced by Messrs. Carter & Co., called the Green Gage Tomato, is very pleasing in appearance and is good in quality, but as a rule it does not grow so large as some others; but one plant I saw had fruit on this year as large as the fruit of Hathaway's Excelsior, which is possibly one of its parents, the growth and foliage being very similar.—J. W. MOORMAN.

### ASPECTS OF NATURE.—SEPTEMBER.

SEPTEMBER is a month not only peculiarly charming in itself with its softened sun and various tints of autumn foliage, but it is dear to us as the last darling of summer, whose latest breath will lead us to chill October's wintry arms.

The present has been an exceptional season, for such blustering winds and heavy rains as we have lately had have this year, indeed, much changed the aspect of the month. Generally it is the time when we enjoy all the full fruits of autumn, while the daily declining sun sheds a mellow light on hill, dale, and mere, and the tranquil skies form a fitting background to the peaceful richness of the landscape. In the woods and fields we miss many of our summer favourites; the wild flowers of the month are neither so gay in colours nor so per-

fumed as their earlier sisters of the spring. Those who would gather them must leave the well-trodden paths and seek for the flowers by the sides of rivers and streams, up on the hillsides, and away over the purple moors, where the blooming heather gives local character and colour to wide expanses of country.

The trees also are fast losing their full foliage or changing the greenery of their summer's prime for the manifold rich tints of their autumnal days. Few of the trees have yet lost their leaves. The *Acacia*, with its graceful pendant foliage that trembles in every passing breeze, is almost as verdant as at midsummer; while the Walnut has changed his darker hue for a brilliant tint of yellow. The Horse Chestnut and the Mulberry are fast losing their summer garb, while the Cherry is turning to crimson, and the Virginia Creeper returns brilliant blushes in exchange for the warm kisses of the setting sun. The Hawthorn berries are ripening, and the foliage of this the sweetest of our wayside trees is gradually changing from green to brown, then to brownish red, and soon as the early frosts have touched it with icy fingers, it will vie in hue with its rich store of dark red fruit. So wet and cold has been this usually delightful month that the birds have already had recourse to the half-ripened berries of the Thorn; a sudden noise at morn or eve will send dozens of birds from many a wayside bush.

It is now the season when the nimble squirrel gets his best feast of Hazel nuts, while leaves still hang plentifully on the trees, and the frisky puck cannot be seen by the prying eyes of the schoolboy who seeks his haunts to lighten his store of winter food. This month also our favourite wayside dainty the Blackberry should be in perfection, but rain such as we have had quite destroys the flavour of this fruit, which is really at its best when gathered in the full sun of an October noon after a light frost overnight; the ripened berries shine out lustrous black, and every tint of the diversified foliage of the Bramble is seen, as well as the pure white or pale pinky lilac blossoms of this beautifier of our hedgerows. The blackbird and thrush now resume their joyous songs during fine days, and the goldfinches again sing. This pretty gay-feathered songster, called by the country people in Derbyshire the "proud tailor," may be seen feasting on the seeds of the Thistle. The fieldfare and the redwing arrive this month to find their winter food of Hawthorn berries on our well-garnished hedgerows; they seek also the exquisitely beautiful wax-like berries of the Yew.

During this "season of mist and mellow fruitfulness" many other birds are often tempted to pour forth notes of gladness, as though the autumn sunshine bore on its beams a promise of another spring. At this time of year two most beautiful English rural pictures may be seen at either corner—east or west—of our little island.

"With ruddy fruit the orchard now is hung,  
The golden Hop droops pendant in the breeze,  
For Autumn from her ample hand hath thrown  
Her richest treasures on the laden trees."

In the "Garden of England," as Kent is called, although many another county in our lovely island might contest the proud distinction of such a title, the Hop harvest is at its height, and many picturesque groups may be seen where the sturdy labourer lifts the pole with its graceful encumbrance of twining bine and carries it to the merry group of women and children who are waiting to strip it as rapidly as possible of its golden treasure. In Devonshire, England's "pomaceous harvests, breathing sweets," blush in every orchard. There the bent and gnarled trees, all venerable with age, their hoary limbs encased in grey-green moss and lichens, offer each season an overflowing store of fruit which, untended, ungathered, grows years after year and drops with mellow richness from the laden boughs on to the thick greensward beneath, until the early frosts have imparted to it the exact flavour so desired by epicures, when it is carted away to the press to be made into Apple wine.

One of the most beautiful features in the landscape at this season is the Bracken, which lights up the scene with its rich fronds—now golden brown, now light as gold itself, or perhaps a few leaves still bear a tint of their original verdant hue. Although the glorious motley of the trees is the most striking object this month, the wild flowers have not quite departed; the stately Golden-rod may still be seen, and the wild Snapdragon finds a congenial resting place on old walls and waste places. In the fields many small bright flowers may be gathered. The tiny Pheasant's-eye still peeps from the stubble; the pretty quaint name given by our grandmothers to this flower was *Rose-a-ruby*. In the same localities the wild Pansy

will grow side by side. This pretty wildling goes in Germany by the name of "Stepmother," in Poland by that of "Brothers-and-Sisters." On a fine day, when

"All heaven and earth are still, though not in sleep,  
But breathless, as we grow when feeling most,"

many a modest wayside flower may be gathered, and what is wanting in brilliancy of colour will be amply compensated for by beauty of form.

The meadows at this season are often as green and fresh as in spring, but they are not gay with Flora's smiles. In place of delicate blossoms they often bear a rich harvest of food in the shape of Mushrooms, which now rise, as it were, spontaneously from the sod, and after dewy nights sprinkle the meadows with balls of snow, or cluster in groups of yellow or brown fungi above the roots of large trees in park and forest. Before the end of the month almost all the corn is garnered, yet in the mountainous districts of Wales and the north of England it still stands, and in unfavourable seasons the stocks are dried by the earlier breathings of October winds. In the southern and midland counties the stubble fields are given up to the sportsman;—

"In his mid-career the pointer, struck  
Stiff by the tainted gale, with open nose,  
Ontstretched and finely sensible, draws full,  
Fearful, and cautious on the latent prey,  
As in the sun the circling covey back  
Their varied plumes, and, watchful every way,  
Through the rough stubble turn the secret eye."

—T. S. J.

### PETROLEUM HEATING THE BOILERS OF HOTHOUSES.

We have been so very successful in making jam by one of these stoves, the copper vessel containing the jam having been set and kept boiling, that it has occurred to me that the same, or if desirable a larger stove, would easily keep a boiler at the required temperature (under boiling I believe), for heating a hothouse.

The stove we used is one of the new and improved burners, the wicks being only two in number, and under 3 inches in width. From my experience of the old stoves, which I have used for two or three years for heating bedrooms, I feel sure there would be no difficulty in keeping a stove burning for eighteen or twenty-four hours at any set temperature; and the ease with which these boilers could be kept at any given heat for the time above mentioned, with the very small amount of care and attention they would want, ought to make them, if properly made and supplied, very valuable, and from the price of petroleum I cannot help thinking cheaper than coke, when it is remembered that there is no waste in lighting or putting them out.—W. T. F. M. INGALL.

### NOTES OF A SCOTTISH TOUR.—No. 4. DRUMLANRIG.

"If you are going to visit Drumlanrig you will see the most finished piece of gardening in the three kingdoms." Such was the observation made to me by one who ought to know; and I can only say after having visited it, as far as my experience goes the judgment is correct, for I have never seen such thoroughness in all the departments of a garden as I saw there. Everything was clean and tidy to a high degree. All the plants requiring stakes were carefully supported, the walks were excellent, and not a weed was to be seen throughout: and now in my poor way I must strive to give an idea of this fine garden.

No two places can be more distinct in character than Castle Kennedy and Drumlanrig. In the former we see a place struggling into existence as it were, for all the deeply interesting part of it is new as I have explained, while at Drumlanrig everything that age can give to a place is present. The old house, the magnificent trees, all tell of an old baronial residence, and give a groundwork for so able and intelligent a gardener as Mr. Thomson to work upon; while, embosomed as it is among hills where the most luxuriant foliage abounds, it has a very different appearance to the somewhat bare character of the scenery around Castle Kennedy. Nothing can be imagined more princely than the general aspect of the place; while, as I shall endeavour to explain, the more one explores it the greater the interest it excites.

On entering the grounds from the Thornhill station one comes at once to Mr. Thomson's house, built on an eminence overlooking the kitchen garden, and replete with the comforts and

conveniences which a thoughtful employer will always see that his employees have. There is probably no one except the steward on whom so much depends as the gardener, and it is a poor policy not to treat him as he deserves. Here from his vantage ground Mr. Thomson can overlook the twelve acres of kitchen garden and see at a glance if all is going on right. On entering one is at once struck with the extreme neatness and order of everything. Outside the wall there is a long border of herbaceous plants, not growing in the admired disorder one so often sees them in, but each in its place with a good legible label attached. On the opposite border and nearer the wall is another long border; at the back a grand row of Delphiniums, each well staked and showing the noble spikes of bloom; in front of them three or four rows of Phloxes, including, of course, all the best of the late-flowering kinds; then Carnations, Roses, &c. On entering the walled garden there is a long range of houses, pits, frames, &c., in which is a fine collection of stove and greenhouse plants, Vines, Peaches, &c., but none of them in a forward state, everything being arranged to suit the visit of the noble proprietor the Duke of Buccleuch, who comes here after the London season for shooting; so that everything has to be arranged for that time, all the requirements of the family during the London season being met by the resources of Dalkeith Place near Edinburgh. In front of the vinery was a long wide border of *Viola cornuta* Perfection in splendid bloom, the centre filled up with the golden variegated Periwinkle and bordered with *Alyssum*. This lasts up to the time of frost, and certainly nothing can be more effective. All this country seems to be the very paradise of the *Viola* tribe, the excess of moisture suiting it well, whereas down south they are burned up. There are 48 inches of rain at Drumlanrig, while with us not more than 21 or 22 are the average. All Mr. Thomson's care has not been able to ward off the ravages of the Phylloxera, and one house had to be destroyed entirely, the only way of eradicating it being to stamp it out. This has been proved to be the experience of all our best cultivators, and happy are they who have not been required to put this experience to the test. And let me say, as a proof of the manner in which things are done here, that the flue of the chimney into which the smoke from the furnaces goes is carried half a mile away amongst the woods, and that the same is done with the kitchens at the mansion, so that no inconvenience from the smoke is felt.

But it is on leaving the kitchen garden that the special glories of the place burst upon you. You enter woodland walks, at every turn of which some new point of interest, some glorious bit of scenery, bursts upon your view. The extent may be gathered from one fact—there are seventy-five miles of drives and the same number of miles of grass walks to be kept in order. And then all at once your eye rests on the pleasure grounds, of which there are fifty acres, some laid out in bedding surrounded by grand timber, and with acres of Laurel hedging, every bit of which is kept close cut with a clasp knife, no shears being allowed to be used. In the lower gardens (for as the house is situated on an eminence the gardens rise up in different levels) there are some beds of Heather kept closely cut, and the tender lively green of this is very charming; in others Oak hedges neatly trimmed are used, and *Verbena venosa* is much more largely employed than I have seen it in most southern gardens. Then at another part is what is called the Duchess's garden, where many of the old-fashioned flowers are to be found, and the air is sweet with Carnations and other plants such as were to be seen in the Lady Corisande's parterre. Then there is the Sand Garden, in which the pattern of the beds is run out in Heather on white sand, tons of freestone being broken up every year for this purpose. On another terrace one comes to an exquisite piece of carpet bedding, arranged with great skill and with a true artist's eye; and then all around the scenery is so grand, the setting of the green so perfect, that one is at a loss which most to admire—the exquisite taste and refinement of the gardening or the beauty of the scenery around. I need not say that there is a most liberal supply of labour, for no place could be kept in the perfect order that this is without that.

I am quite aware that this is a very imperfect attempt at setting forth the beauties of Drumlanrig. But what can one do? How many a time have I read graphic descriptions of places, but which when I saw them turned out to be so very different to one's expectations. I would gladly have added an engraving from a photograph, but it is forbidden; and I have only left to me now to record my obligations for the kindness

and hospitality with which I was received by one who holds so high a place in his profession as Mr. Thomson.—D., *Deal*.

### STRIKING CUTTINGS.

VARIOUS modes are adopted in striking cuttings, and the following American plan is recommended in the *Rural New Yorker* as being simple and effectual:—

"A flower-pot 8 inches in diameter answers as well as any other size, though of the two a larger rather than a smaller is to be preferred. Place an inverted flower-pot saucer within the pot, of a size large enough to rest about midway or a little below. This serves the threefold purpose of (1) perfect drainage, of (2) affording a firm base for the sand, and of (3) dispensing with a greater body of sand than can be of any use. Of course, other drainage material may be used if saucers are not at hand—but we prefer the saucer for the reason that it has given us better success. Aside from any philosophical causes as to its greater efficacy, its use is less troublesome than to half fill the pot with broken crocks, stones, moss, or what not; it is a cleaner method; the weight of the pot is less, and that it is more effectual in practice will appear to others as it has to us upon giving both a fair comparative trial. When there is bottom heat perfect drainage is of little moment, since the immense evaporation caused by the heat and shallowness of the boxes generally used renders it unnecessary. But without bottom heat, unless the drainage is perfect, the water very soon stagnates, and the resulting acids cause the cuttings to damp-off at once.

"With the space in the pot beneath the inverted saucer empty, let us fill to the brim above with coarse sand, as coarse as is used for mortar—first sifting and washing it until thoroughly cleansed. Place it on a rack or stand in a window which receives the morning sun until noon and saturate it with water. Another saucer or some other vessel will be required to receive it as it passes through. We need not, as when flat boxes are employed, so much fear watering too much, because the water passes freely away and can never become sour. It is only necessary, however, to preserve the sand constantly moist.

"An 8-inch pot will accommodate twenty cuttings. Make them from 2 to 5 inches long, depending, of course, upon what they are. At this season of the year more leaves may be permitted to remain upon them than earlier in the season, when the sun is higher and the air less cool and moist. Use a sharp knife, and make smooth cuts just beneath the joints or nodes—strip off the leaves nearly to the top, and insert them about an inch in depth.

"The development of new leaves or buds will generally indicate the proper formation of roots, when the cuttings are to be pricked out and planted in small pots of rich sandy soil.

"One of the greatest drawbacks to the thrifty growth of house plants is the use of clayey soil that, becoming hard—almost solid in fact, is impervious to both air and moisture. The plant must suffer, and all the doctoring in the land is not going to help it while thus strangled.

"As to the number of leaves to be left upon a cutting, a little experience is required to determine. If too many are left the cutting is exhausted, and the formation of a callus (which is simply the healing-over of the wound) and roots is retarded. If all the leaves are cut off or too few are left the same effect is produced, though from a quite different cause. No better hint can be given than that the drooping of the leaves for any length of time after the cuttings have been inserted is an indication that they have too many. Where a leaf is too large it may be cut in two, as in the case of *Aristolochia siphon* (the Dutchman's Pipe), *Hydrangea quercifolia*, &c."

### THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 12.

A BOTANIST whose standing in science gives him a right to be heard demurs to my assumption that the Blacklands estate, situate in Chelsea and Pimlico, was so called because the ground was darkened with an undergrowth of a species of Heath, probably *Erica tetralix*. I grant the difficulty there is in establishing a negative, and therefore allow my opponent all the chances I can; but it by no means follows, because at a time when England boasted so few botanists no one recorded the occurrence of this Heath on Chelsea Common and the adjacent Blacklands, that the species did not grow there, for from more than one reference to this district by historians who make no pretensions to be naturalists, we gather that it

was covered with Heath and Furze. The Heath, it is true, might be the well-known common Ling (*Calluna vulgaris*); but as the *E. tetralix* has been in recent years obtained from such open places in Middlesex as Hounslow and Hampstead Heaths, the soil and circumstances of which place them in near relationship to Chelsea Common as it was in Stuart times, the conjecture that some species of *Erica* may have grown there freely cannot be deemed a very wild one.

Concerning this Blacklands estate, on a part of which, as already stated, the Sloane Street Nursery was formed, it should be said farther that when, in the early part of this century, houses began to spring up on the "eligible sites" it offered, a large portion of it to the west of Sloane Street still retained a semi-rural aspect. A road, now lined with houses and called the Marlborough Road, seemingly formed its boundary to the west, and it is singular that this road, now of minor importance, is of much older date than the far more frequented Sloane Street, which leads directly from Hyde Park to the Thames. In this road and on the Blacklands property was an old house and grounds once belonging to Lady Matthews, then afterwards used as a tavern and the ground cleared for a cricket field. Whether the next stage in its history was its being built upon is not ascertainable; if intermediately it was occupied by one of the market gardeners who had land, some seventy or eighty years ago, on the southern side of this estate, it would be curious, since we have a modern instance in this same neighbourhood of a nursery ground becoming a cricket field. At the period to which I am referring the situation of the private residence called the "Pavilion" must have been an agreeable one, for it had a considerable extent of park-like land belonging to it, and on three of the sides there must have been situate nurseries or market gardens. This "Pavilion" is now being demolished to make way for a new line of road, and he who wills may wander over what yet remains unbuilt upon of the grounds, which are memorable because they once bore touches of the handiwork of the celebrated "Capability Brown," landscape gardener, and, on his own testimony, almost divine in the skill he had in making art equal or even surpass nature. The unkind critics, however, made much fun over his landscape scenery, with its central pond or winding stream, its formal tree clumps and background of shrubs. Did he invent or only re-introduce here the "ha-ha fence," once so admired? The chronicles of horticulture are not clear on the point.

Of the market gardens once in the angle between Marlborough Road and Cadogan Terrace the history is also a blank, unless it is to be supposed the King's Road Gardens extended as far northward, which is very unlikely. And I would here take the opportunity to say, that towards ascertaining the history of nurseries which have long disappeared and left no trace the exertions of one individual cannot effect much. There are doubtless yet living, and resident in London, persons who have recollections of their own of extinct market gardens of half a century since, or family traditions going back further still. Any duly authenticated facts, if communicated to the office of this Journal, will be gladly received and acknowledged by the author of this series of articles.

Nearer Knightsbridge, and on rather higher ground, but belonging to the Blacklands estate, and north of the "Pavilion," was Catleugh's nursery and market gardens, well known in the Georgian era, and not yet out of existence, though the land has grown "small by degrees and unbecomingly less." Evergreens and a choice variety of exotics were reared here successfully and profitably before the torrent of suburban life set westward. Pines also were cultivated largely, to find a ready sale when the importation was but small. The erection of the church and schools of St. Saviour's, Upper Chelsea, absorbed a part of the land used as a market garden, and about six or seven years ago another part was cleared to form the Prince's Cricket Ground, much honoured by fashionable folks of this day. Mrs. Catleugh died five years since, and the present owner anticipates that he will have very speedily to relinquish, for local improvements demand even the small space now cultivated behind Hans Place. Perhaps, under circumstances, the disappearance of the nursery is not to be regretted, since only one greenhouse survives, and the open ground is found chiefly available for the cultivation of—Rhubarb. Knightsbridge, let it be observed, must have been a capital screen to the old Chelsea market gardens at the period when it had only a house or two upon its edge, and thick shrubberies which, rising toward the north and east, would shut off the keen winds; for it is quite evident that Knightsbridge, which took its name from the king's or knight's

bridge over a little brook, was originally a portion of the same large forest which stretched northward from Hyde Park towards the hills of Highgate and Hampstead. Many of the trees in Knightsbridge were felled during the seventeenth century, and an antique plan of this locality, attributed to the end of that century, shows two or three plots of land laid out in market gardens, one of these belonging to a Mr. Calloway, and bearing the name of Quail Close, suggesting that partridges used to be seen or hunted for there. Mr. Wiltshire also was a holder of land, and an entry in the Chelsea records informs us that this same Jeremiah Wiltshire (I presume) was fined in 1705, with Thomas Robinson, for "having made a pond or water-place for the rotting of dung, and for having deposited a heap of mould on the Common." Most probably wanting space in their ground for the preparation of the manure they employed, these gardeners made free with the Common, not meaning any harm, and no doubt they paid the fine honourably. But the trivial incident illustrates that an era of improvement in plant culture was coming on, due to intercourse with the Continent. The inhabitants of Chelsea seem at times to have been very particular about their Common, and at other times lax, for when the above occurred a lease had not long expired by which they had let a part of the Common for twenty-one years to Abraham Stony, a market gardener and farmer; and from a condition that he was to put upon the land a specified quantity of manure during the last three years of his occupancy, it may be supposed that he cultivated the land and did not merely turn it into a pasture, for Chelsea was famous for its cows all through the Stuart times, and its repute for custards lasted till the reign of George I.

Changes great and small, as I have hinted, were to be ascribed to the revolution of 1688 and the influx of Dutch gardeners, and one of the effects was a stimulus given to the culture of Asparagus, for it was a much-admired esculent in courtly circles. From the mention of it by some writers one would almost be inclined to think its season lasted longer then than now, when public taste demands a succession of vegetables. It is true King William's mode of eating Asparagus was peculiar, for he devoured the stalks, and hence guests at the royal table felt themselves embarrassed, for to leave one's stalks upon the plate was as good as implying that His Majesty was guilty of an act of indelicacy. And here and there on the "Five Fields," now covered by the mansions of Belgravia, Asparagus was grown in the reigns of William and Anne, perhaps later, though the ground was not generally cultivated, and much of it continued to be waste or common land until the present century had long ceased to be new; but the earlier market gardeners of Chelsea had most of their ground farther up the King's Road, and only cultivated a few patches of ground in the "Five Fields." There were some in the reign of Charles II., and several of these were living in the time of George I., and able to testify from their knowledge and personal experience that there was a right of way across the "Five Fields," for a succession of attempts was made by court officials to exclude gardeners and other persons from what was called the "King's Private Road," and the names of the following gardeners can be quoted as uniting with the lord of the manor and other Chelsea residents to secure an unquestionable right. These names are J. Franklin, E. Anderson, J. Lindford, M. Hutchins, and N. Perritt, all of whom either owned land abutting on the "Five Fields," or had for various purposes travelled with their carts or without them along a road from which the King wanted to shut out the public. And it is a curious bit of history that comes out in one of the documents connected with this affair, that a great deal of the produce sent to the markets was carried on the shoulders of men and women; no doubt the reason was that vehicles could not pass through the park, and the roads through Westminster were but so-so. The Hutchins family, it may be remarked, has had a long connection with Chelsea as farmers and market gardeners, and at Chelsea Farm, once situate near the Vestry Hall on the opposite side of the King's Road, a notable murder was perpetrated by some Jews. Lindford the gardener showed some spirit, for it is stated that when he met the King's surveyor he was asked where he was going, and he answered he was going to his own land, and the surveyor could not stop him nor anyone else; "whereupon the surveyor said no more." The gardeners not only won the day, but also gained a strip of land which had been taken from them, and the King's surveyor had orders to re-open some ditches he had filled up. Vegetables, it would seem, were principally cultivated by these gardeners. Some fruit was

sent to the market from Chelsea orchards, but they were situate further westward towards "Little Chelsea," afterwards "Brompton," lastly "South Kensington." The story of the nurserymen of Chelsea belongs to a later period, which we shall have to consider hereafter.—C.

### NOTES AND GLEANINGS.

THE nursery of Messrs. Veitch at Chelsea can never be visited without finding something, especially amongst the ORCHIDS, to admire. A few which are flowering now are the Vandas—tricolor, suavis, and cærulea, which are very fine. Mr. Dominy's grand *Cattleya C. exoniensis*, and one of its charmingly marked parents *C. maxima*; *Oncidium varicosum*, a grand spike; *O. leopardinum*, extremely rich; *Cœlogyne Cumingii*, waxy white, with lemon-coloured lip, and sweetly scented; and *Cypripediums*. *Lapageria alba* in the long corridor is also extremely beautiful, the large waxy flowers with which the roof is covered producing an effect which cannot be equalled by any other greenhouse climber.

— WE had lately an opportunity of inspecting the new CRAIGLEITH NURSERIES of Messrs. Ireland & Thomson, Comely Bank, Edinburgh, and we were quite surprised to find the rapid progress that has been made in the way of getting everything into working order, especially about the houses. The glass ranges are very extensive, and they are all constructed on the most improved principles. All the houses are span-roofed and exceedingly well adapted for nursery-plant culture, being comparatively low in the roofs and glazed with large wide panes of glass, which are much more conducive to plant health than lofty dark erections. The propagating house and most of the other tender-plant houses can be reached from the potting shed without going into the open air, and all the houses are conveniently placed together. Many of them are already well stocked with healthy young stove and greenhouse plants. The heating, which extends to some thousands of feet of 4-inch piping, is all done with one of the largest of Meiklejohn's improved cruciform boilers, which bears a good name in Scotland for its economy and power.

— A NEW variety of *LILIUM auratum* has just been flowering in Mr. Bull's nursery at Chelsea, which is so distinct and beautiful as to merit special notice. We saw this flower in its faded state, and it then measured over 12 inches in diameter. It is quite dissimilar from the usual type of *L. auratum*; indeed *auratum* as applied to this variety becomes an anomaly, for there is no ray or spot of yellow, that colour down the central petals being substituted by what is now in the flowers' fading state a band of reddish maroon, but when fresh was a rich blood colour. The petals are also heavily spotted with the same rich colour. This is a gorgeous Lily, and has been recommended by a good authority to be named *L. auratum cruentum*. In the same establishment we saw flowering the beautiful new *BOMAREA*, *B. Carderi*, which was so conspicuous in Mr. Bull's group of new plants at the Royal Aquarium on May 30th. The plant then was small, and its flowers were few, but it is now large, and on one umbel there are twenty-three miniature *Lapageria*-like flowers of a rosy pink colour. The plant is trained to the roof of an intermediate house, and its flowers are both novel and attractive. It is a very distinct plant, and will probably flourish in a greenhouse temperature.

— WE are informed that the late EXHIBITION AT DUNDEE was, notwithstanding the inclement weather which prevailed at the time, financially successful. Thirty thousand persons visited the Show, the total amount received being £1700, and that after paying prize money to the amount of £1013, and other expenses, a satisfactory balance will remain in the hands of the managers. A result so gratifying will afford encouragement to our enterprising Scottish friends and stimulate them to further endeavours in the future.

— IN addition to the greater parks of London vested in the Crown, but open to the public, the Metropolitan Board of Works state, in the report they have issued this year, that there are under their management about 1100 acres of PUBLIC RECREATION GROUNDS in various parts of the metropolis and its suburbs. There is Blackheath, comprising 267 acres; Hampstead Heath, 240 acres; Finsbury Park, 115 acres; Southwark Park, 63 acres; Hackney Downs, 50 acres; Well Street (Hackney) Common, 30 acres; North and South Mill Fields, 57 acres; London Fields, 27 acres; Tooting Beck Common, 144 acres; and Tooting Graveney Common, 63 acres. The gardens on the Thames Embankment and in Leicester Square present

14 acres. The remainder of the 1094 acres is made up of Clapton Common, Stoke Newington Common, and Shepherd's Bush Common.

— THREE MUSHROOMS close together at Dunlaven, Ireland, were of the following great weights and dimensions. They were common field Mushrooms. The weight of the first was 12½ ozs., and its circumference 27 inches; the second, 10½ ozs., and circumference 21 inches; and the third, 7 ozs. in weight and 18 inches in circumference.

— ON the 21st inst. the Master (Mr. J. Stroud) and the municipal members of the Fruiterers' Company waited upon the Lord Mayor at the Mansion House, and, in accordance with an ancient custom annually observed, presented for the acceptance of the Lady Mayoress and himself a splendid assortment of all the CHOICE FRUITS OF THE SEASON. The gift, which was very tastefully laid out in the saloon, included Pine Apples, Melons, Pears, Damsons, Figs, Apples, Grapes, and Walnuts. The Master, addressing the Lord Mayor and the Lady Mayoress, assured them that it gave the Fruiterers' Company great pleasure to tender year after year their respectful homage to the Chief Magistrate of the City, and their only regret was that having neither orchards nor vineyards of their own, they could not describe the fruit as "home-grown." The Lord Mayor, in a few appropriate sentences, thanked the Company for their valuable and seasonable gift, which annually and pleasantly connected their Guild with the head of the Corporation of London for the time being, and added that, also following the ancient custom, he would have the honour of entertaining the Company at dinner at the Mansion House in the course of the next month. After taking some light refreshments the Company retired. It was formerly the practice for a staff of gaily-dressed porters walking in single file to bring the fruit through the City from Farringdon Market; and the Lady Mayoress, it is said, not only gave each carrier a bottle of wine to take home in his empty basket, but, as the Ceremonial Book has it, "regaled" them with a dinner.

### NOTES ON VILLA AND SUBURBAN GARDENING.

FLORIST FLOWERS AND BEDDING PLANTS.—After this month is out the winter culture of plants under these two headings may be said to have commenced. Heavy rains and cold nights with sharp white frosts which may come at any moment, suggest that it is best to be on the safe side by placing the plants under glass coverings where the lights can be thrown off in fine days and put on at nights, admitting air all night if the weather should be suitable.

Amongst the most prominent of winter-flowering plants are Primulas. These should mostly be establishing themselves in their flowering pots, and the plants should almost have attained their full growth. They should now be protected both by day and night, and be kept as near the glass as possible so that the plants may not be drawn. A span-roofed glass case placed on a bed of coal ashes is one of the best structures for them. These cases are shallow and allow of air being admitted under them, and as they also admit plenty of light all round, they are particularly suitable for preserving the lower foliage of the plants. The second batch of plants, a few of which ought always to be grown to come in with bulbs towards the spring, must be kept growing all through next month as fast as possible, and after being put into their winter quarters be kept rather moderately watered, and have the flower stems picked off till the days begin to lengthen in January, when the plants may be allowed to flower. Weak guano water applied twice a-week after the plants show signs of flowering greatly improves the plants and flowers. Particular care is necessary in watering Primulas; for if the plants should happen to be potted rather low the water overflows their necks, and if allowed to lodge there the chances are that the plants will die-off in considerable numbers. A light soil potted rather firmly with the necks of the plants nearly level with the rim of the pot and good drainage are very essential in growing Primulas. They do not need so much water as some plants, but it must pass away quickly.

Cinerarias are also important plants for flowering in winter and spring. They ought to be at once shifted into their flowering pots; and although these plants grow most freely in the open air during September, it is not safe to trust them out much longer. The soil they do well in is composed of two parts of turfy loam—if laid up for a year so much the better—one part of sandy fibrous peat, and another part of well-decayed leaf soil, adding before potting a liberal admixture of sand. I like also to add a little powdered charcoal both in the soil and drainage. Cinerarias should be potted firmly, as the roots are fine and take hold of the soil much better than when potted lightly. After potting place the plants on an ash bottom in a cold frame, and after a few days if the weather is mild let them have a little

air under the frame as well as at the top. These plants make their leaves close on the top of the soil, therefore before watering examine the soil of each pot to make sure that water is needed. Roots are also produced on the surface of the soil. These roots must be taken care of, as no doubt from them the fine, broad, stout foliage is supported. All suckers or side shoots may be taken off, as the plants grow sufficiently large for decorative purposes without them. Cinerarias are in many places kept in good health in cold frames all through the winter; at any rate they do better in such places than on the dry boarded stages of a greenhouse. If kept in frames they must be sufficiently protected from frost, and have all decayed matter carefully removed from them.

Calceolarias, too, will now need some attention. Ours are pricked-out in pans and protected with hand-lights. They grow more during winter than at any other time. They, too, will do wonderfully well in a frame in winter, and do not mind a little moisture on the foliage provided it is not stagnant. They must be shifted into larger pots as soon as the roots reach the sides of the small pots, not allowing them to become matted together, or the plants stop growing and send-up flowering shoots; but if shifted judiciously and the flowering shoots are picked off, very fine plants are produced which flower in April and May. In the spring when the days have become warm a sprinkling of water over the plants and around the pots helps to strengthen the foliage very much. They must have plenty of air, and a temperature of 45° or 50° will grow them well. Two-thirds of rich light loam, the rest leaf soil and sand, or if no leaf soil is at hand, one part of very dry flaky cow dung sifted through a fine-meshed sieve, adding a little charcoal as stated for the Cineraria, will be very suitable, and in this compost the plants ought to thrive well.

Chrysanthemums now require training, as they are just growing into large plants and are setting their flower buds. Use as few sticks as possible; the disturbed foliage will return to its natural position after tying. Each shoot should be tied outside of the sticks in order to hide them as much as possible. Now is the time to give these plants weak liquid manure twice a week, which will help to keep the leaves healthy and assist in swelling the flower buds. If dry days should come on the plants must be sprinkled overhead in the afternoon, for if a plant loses its foliage before flowering it is an unsightly plant, and will not flower in any way satisfactorily. If it is required to have plants in small pots many of the medium-sized shoots should be taken out, and in order to have fine large flowers some of the buds will need thinning-out, but in our case we want as many flowers as we can possibly produce.

**BEDDING PLANTS.**—Complete the propagating as quickly as possible, and where there is no room to put the cuttings under glass they ought to be arranged in beds, and have a covering of canvas placed over the glass at night. Our Geraniums, Verbenas, &c., are all exposed outdoors and most of them are rooted. We have already had slight frosts, which have altered the colour of Alternantheras and some other tender plants, which is a hint that a watch must be kept, and shelter must be in readiness for plants which we wish to preserve. Heliotropes, Nasturtiums, Lobelias, Verbenas, Alternantheras, Mesembryanthemums, Abutilons, Salvias, Petunias, and other softwooded plants have been put in thickly in pots; these plants will be considered as store plants through the winter, and will be potted-off early in the spring and propagated from as quickly as possible. We have not room to treat them more liberally. A few old frames are in readiness to receive old plants that are to be taken up from the beds. Dahlias, Salvias, &c., will be stored in a dry shed.

Our attention will next be turned to preparing a place for bedding Calceolaria cuttings. The plants will be left as long as possible, and the cuttings will be taken just before frost and inserted in frames. At the same time cuttings of the Golden Chickweed, Pansies of the common sorts, Gazanias, Gnaphaliums, and Alyssums will be put in, for we find all these to keep well with the Calceolarias. The cuttings of Calceolarias and Alyssums will not bear the sun, therefore these are put in together so as to be shaded; the others are not shaded at all. A bed of soil is made up, and a frame placed upon it and filled-up with good cuttings, the soil being within a few inches of the glass, and the cuttings generally root quickly and well.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

USUALLY at this season of the year there is plenty of vacant ground requiring to be dug or trenched, and when time can be spared it is always best to trench vacant ground instead of digging it; and just a word in passing about trenching. As a matter of course, if this can be done early in the autumn when the ground is dry, so much the better in many ways—it is better for wheeling the manure, so it is easier to move soil that is comparatively dry than when it is saturated with water, and in

early spring soil that has been worked in the autumn is much better adapted for all kinds of crops than that worked in the dead of winter. Further, it is not uncommon for men to be sent to trench a piece of ground that has been made hard by frequently trampling upon it, and they fork the hard lumps into the bottom of the trenches without taking any pains to break them up. The proper thing to do with hard ground is to fork it up, first breaking the top spit well during the process. If the ground can lie a week or two in this state so much the better. Another object to be attained by trenching is to give a larger dressing of manure to the ground than could be applied if it had only been dug. A good way to apply the manure is to spread a thick coating over the surface of the soil, and as the first spit of earth is forked into the opening that has been made at one end of the ground, the manure becomes mixed with it. The loose soil should then be thrown in with a spade or shovel, another dressing of manure may be placed over this, then a spit of earth, and another shovelling from the bottom of the trench to finish. It is a further advantage to fork-up the hard bottom. In this way, by taking two spits and two shovellings, the ground is stirred-up to the depth of over 2 feet. If the ground requires digging only, let it be done to a uniform depth and as neatly as possible, and whether it is dug or trenched it ought to be left perfectly level.

The dry weather has been very favourable for earthing-up Celery. It is too early yet to earth-up the general crop, but that required, say, a month or six weeks hence, may now be earthed-up. In our district it is quite necessary to water late crops to prevent them from running to seed. Celery requires a considerable supply of water at the roots, and when soil has been added to it for a distance up the stem the surface may be quite moist, and underneath where the fibrous roots are at work the ground may be quite drained of moisture. If the ground is not yet prepared for spring Cabbages it ought to be done at once. A good dressing of manure is necessary, as the Cabbage is a very gross feeder, and the quality is deteriorated when the plants are grown in poor soil. The hoe should be freely used amongst autumn-sown Onions, Spinach, Lettuce, and other crops.

### MELONS AND CUCUMBERS.

So far the weather has been all that can be wished for the ripening of Melons and the growth of Cucumber plants; for without vigorous growth good-flavoured and handsome Cucumbers are not possible. When the Melons are grown in houses properly constructed and well heated the requisite night temperature, 65°, can easily be kept up, and if the fruit is ripening a little air should be admitted all night at the apex of the roof; but artificial heat, though necessary to obtain good Melons at this season, cannot compensate for want of sunshine, and it is principally on the amount of sunshine the plants receive that the flavour of the fruit depends. The plants should be well watered at the roots until the fruit is within a week of changing, and no more ought to be given, and it will not be necessary now to throw much water about on the paths and walls of the houses. Melons in frames are not likely to be of good flavour, for long and cold nights tell upon the plants. If the night temperature should continue to fall as low as 45° it is of much advantage to throw a mat over the frame, and the heat might be further kept up by a lining of hot manure, leaves, or the sweepings from the lawn.

Our Cucumber plants in the house have continued to bear abundantly since March, and the vigorous growth they now make gives promise that they would bear until March comes round again. Messrs. Kelway of Langport sent seeds of two new varieties for trial. Both of them have turned out well, and have held their own against Tender and True, which was planted with them for comparison. Kelway's Conqueror is a very prolific variety, and is distinct from any other sort that has been grown at Loxford. It resembles in many respects a variety that is grown to a large extent in the neighbourhood of Cheltenham, and that has been frequently exhibited under the name of Dreadnought. It is an excellent Cucumber both for summer and winter use. The other sort on being compared with Tender and True is so like it that many persons have been deceived and thought that it was that sort. It is strong in growth, bears freely in winter as well as summer, and is also well adapted for exhibition. Mr. Kelway has named it Kelway's New Winter Cucumber.

We shall clear out our old plants in a few weeks, and plant the same varieties again. The plants have been raised from seeds, and will come into bearing a few weeks after they are planted out. We pot the plants on into 8 and 9-inch pots. What with syringing and moisture in the house, the glass over the plants has been quite obscured with a greenish substance that generally accumulates when the glass cannot be washed. When the old plants are removed it will give us a chance to have a thorough clean-out—both glass and woodwork will be washed over with warm soft water.

### ORCHARD HOUSE.

All the fruit has been gathered now and the trees reotted

It is better to repot annually than it is to surface or top-dress the trees. Somehow worms will work up into the pots, and in other ways the drainage becomes choked in the course of twelve months, and with the annual potting fresh soil is placed all round and under the roots, whereas by merely digging out a certain quantity from the top and partly down the sides the fresh soil does not come into immediate contact with the roots. We always repot before the leaves fall—indeed, no time is lost, so that the potting, as it has been this season, has been finished by the middle of September. The trees are now making plenty of fresh roots, and they will be well established before the cold weather sets in. The secret of success in potting at a time when the trees are in full leaf is to take care that the leaves do not suffer. It is not necessary to shade the glass, but simply keep the ventilators a little close and the leaves moist by frequent davings overhead with the fine rose of the syringe or garden engine. When the new rootlets are formed the trees require plenty of water at the roots.

#### GREENHOUSE AND CONSERVATORY.

We are rather short of fine flowers at this season in the greenhouse, but when this is the case those that we do have are more highly valued. A number of plants of *Bouvardia Vreelandii* and *B. jasminiflora* had been out of doors during the summer; they are now either in flower or in bud, and a continued succession of them will be obtained until Christmas. For variety *B. Hogarth*, with bright red flowers, is very useful for cutting.

*Nerium Oleander* has been in flower for a month, and the plants look as if they would produce a succession for a month or six weeks longer. This fine old plant is not so much grown as it ought to be. Cuttings struck at this time last year now flower freely in 6-inch pots, and old bushes liberally treated make exceedingly handsome objects in the greenhouse or conservatory. One not unfrequently sees them producing plenty of leaves and long willow-like growths with few flowers. This is because the plants have not been allowed a season of rest. When the plants have finished flowering a good place for them is a cool dry vinery, and no more water ought to be given than just sufficient to prevent the plants from flagging. During the growing season water should be plentifully supplied to them. The *Oleander* does well in a compost of sound turfy loam with a third part of turfy peat and a little decayed frame manure added to it.

*Stage Pelargoniums* have been repotted, using clean pots a size smaller than the plants were grown in previously. The large exhibition plants are grown in pots 8½ inches in diameter, and it is astonishing to see the immense plants quite 18 feet in circumference, furnished with hundreds of well-developed trusses of flowers, and at the same time healthy green leaves in pots of this size. In order to produce fine plants the potting material must be of the best, and manure water has to be liberally supplied. Such plants must be turned out of their pots now; a large proportion of the roots and exhausted soil should be removed, and the plants be repotted into pots 7 inches in diameter. The plants should be repotted when the growths are an inch long. If the growths become too long the plant suffers when the roots are reduced. A very good compost for stage *Pelargoniums* is good turfy loam four parts, one part decayed manure, and one part leaf soil. The loam should be of a moderately clayey nature, and when this is the case a sufficient quantity of silver sand should be added to keep it open. An 8-inch potful of bone dust should be added to each barrowload of the loam. Fancy *Pelargoniums* do not succeed in a compost so strong as the above, and a little more sand should be added to the soil.

Training specimen plants of *Chrysanthemums* and looking over those plants grown for the beauty and size of their flowers, removing all superfluous buds, and dusting with tobacco powder where there is any appearance of green fly, are matters which are now receiving our attention.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

William Knight, Floral Nurseries, Hailsham, Sussex.—*Catalogue of Roses, Coniferae, Fruit Trees, &c.*

Samuel Yates, 16 and 18, Old Millgate, Manchester.—*Illustrated Catalogue of Dutch and other Flower Roots.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

ALEXANDRA PALACE (Potatoes). September 28th and 29th. Mr. John McKenzie, 1 and 2, Great Winchester Street Buildings, London, E.C.

HULL. October 10th, 11th, and 12th. Mr. J. Chappell, 96, Prospect Street, Sec.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

MARGATE. August 29th, 1877. Mr. C. D. Smith Hon. Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

APPLES WANTED.—Several correspondents would be obliged by "J. J. Lancashire," stating where Domino, Greasy Coat, Pike's Pearmain, &c., can be purchased.

APPLES AND PEARS (Rev. R. G.).—Write to Messrs. Webber & Co., Middle Avenue, Covent Garden Market.

PLUM TREE THROWING-UP SUCKERS (F. M.).—Just in proportion to the number thrown up is the tree injured by them. The best way is to work down, and cut them off close to the roots from where they spring; the usual way is to chop them off carefully with a spade. You may either prune the tree now or any time through the winter.

OLDEST VARIETY OF THE APPLE (Devon).—We cannot tell which is the oldest variety still in cultivation, but we do not think it is the Golden Pippin. We do not know which of our present Pearmain is that mentioned more than five centuries since, or whether new varieties have had that name applied. In the reign of Edward I. Walter de Hevene held the manor of Runham in Norfolk on condition that he rendered to the king annually two measures (muts) of Pearmain cider.

RASPBERRY CULTURE (M. C. Ellis).—There is no special treatment required to grow Raspberries if the soil is suitable. They like soil deep, rich, and moist. From four to six canes is a sufficient number from one stool. Have you good varieties? If you have them not, try Fastolf, Carter's Prolific, and Red Antwerp.

PEARS AND PLUMS FOR ESPALIERS (Idem).—Pears: Louise Bonne of Jersey, Williams' Bon Chrétien, Marie Louise, Doyenné du Comice, Winter Nelis, and Joséphine de Malines. Plums: Victoria, Prince Englebert, Green Gage, Kirke's, Jefferson's, and Cox's Golden Drop.

FRUIT TREES FOR UPRIGHT CORDONS (Durham).—Pear trees are best adapted for this purpose, but in your district it would be as well to try a few of the finer sorts of Apples. We should plant of Pears—Beurré d'Amanlis, Louise Bonne of Jersey, Beurré Hardy, Van Mons Léon Leclerc, Madame Treve, Easter Beurré, Doyenné du Comice, Glou Morcean, Bergamotte d'Esperen, Marie Louise, Winter Nelis, Suffolk Thorn, and Beurré Diel. Of Apples—Kerry Pippin, Cox's Orange Pippin, Golden Pippin, Ribston Pippin, Scarlet Nonpareil, Nonpareil, Braddick's Nonpareil, Margil, Mannington's Pearmain, and Sturmer Pippin.

LEAN-TO PEACH HOUSE (Tommy).—Your back wall being 12 feet high, and the width of the house 10 feet, we should have 3 feet of front lights upon 10 to 12 inches of masonry above ground, the whole of the front lights to open, and corresponding lights at the top of the house, also opening the full length. We should have trees upon the back wall for at least a time, as they will bear well until too much shaded by the trees in front; and if you wish to retain the trees upon the back wall in a fruitful state, the trees upon the trellises in front must not be allowed to extend more than two-thirds the extent of the roof. The trellis should be 15 inches from the glass. You will have room for six trees, three in front and the same number at back, or you may have eight at 12 feet apart. The best Peaches are Dr. Hogg, Crawford's Early, Grosse Mignonne, and Noblesse, to succeed which are Barrington and Princess of Wales. Nectarines—Lord Napier, Pine Apple, Elruge, and Violette Hâtive. See also Mr. Taylor's list of successional Peaches in the present issue.

VINES FOR VINERY (Idem).—You will only have room for four Vines upon the front, and they would not succeed well upon the back wall. Black Hamburg and Muscat of Alexandria are the best of all Grapes. We should have two Black Hamburgs, one Madresfield Court, and one Muscat of Alexandria, or Foster's White Seedling if you do not intend to ripen with heat.

SEEDLING BEGONIA (Typo).—It is quite a novel form, and as the plant is of good habit may prove an acquisition.

EVERGREEN CREEPER FOR PORCH (D. D.).—Not one of the Tropæolums would serve your purpose, as frost is not excluded. The Irish Ivy is the most desirable. For decorating any charcoal in powder is effective.

FORCING RHUBARB (A Young Amateur).—We do not understand what is meant by a "tunnel," but we apprehend it is constructed of fermenting materials, and is made as follows:—The space for the Rhubarb is marked out by stakes being driven into the ground, a dry sheltered situation being chosen, and are kept 3 to 3 feet 6 inches above ground. The sides of the bed are formed by nailing any old slabs of wood to the stakes, not being particular about the boards being close; all that is needed is to have the sides and ends sufficiently stable to keep the fermenting material from the enclosed space, which may be 3 to 4 feet wide, and of any length desired. The Rhubarb roots are put in the bed rather closely together, but so as to admit of some rich soil being placed between and made compact about the roots. The sides of the frame have fermenting material placed against them, the top being covered with slabs, and covered in a similar manner to the sides, a heap of fermenting material being raised around and over the bed so as to produce a temperature in the "tunnel" not exceeding 65°. In this way fine stalks of Rhubarb may be had in three weeks to a month. The end of November or early in December is a good time to commence forcing. The best heating material is an admixture of stable litter with leaves, but sweetened stable dung answers well.

HERBACEOUS CALCEOLARIAS DAMPING OFF (E. H. S.).—The atmosphere has probably been very moist and close, or damping has resulted from too frequent and heavy waterings. There is no book treating separately on soft-wooded plants.

**WINTERING SEMPERVIVUM CALIFORNICUM, WIGANDIAS, AND CANNAS (A. B.).**—*Sempervivum californicum* is quite hardy in well-drained soil, but if you have the offsets in pots they may be wintered in a cold frame or house, keeping rather dry. The *Wigandias* should be taken up and potted before frost, and be afforded a light airy position in a house from which frost is excluded. We should not cut back until spring, and then encourage fresh growth in a hotbed, hardening well off before planting out. The *Cannas* should have the roots taken up after the first frost, be laid in a shed a few days to dry, and be packed away in sand in a place safe from frost, potting them in March and forwarding in a hotbed.

**TROPEOLUM SPECIOSUM AND T. PENTAPHYLLUM (Franklin).**—Keep them in the pots over the winter in the greenhouse, and plant out in spring—late in March or early in April. *T. speciosum* flourishes best in peat soil, and would be most likely to thrive with you upon a west aspect. Planted in an American bed the shoots should ramble over the plants, and when in bloom in late summer they produce a fine effect. *T. pentaphyllum* will now be growing, and should be planted out if you intend to treat it as a hardy subject, but we should give it a position in a cool airy part of the greenhouse. If planted outdoors a south aspect should be afforded it.

**BOUSSINGAULTIA BASELOIDES (Idem).**—We think the spotted condition of the leaves is due to excessive moisture, especially over the foliage, which should not be syringed, the foliage being of a thick texture. We also think you have overwatered the roots, though when growing freely the plant requires to be copiously watered, but to be kept rather dry in winter. We should prefer planting it out, training the shoots to a pillar or trellis in a light airy position. It flowers in late summer or early in autumn, and is very fine.

**SOOT WATER (Idem).**—After being allowed to settle the clear liquid is good for syringing with, but for watering the liquid should be well stirred up each time it is used. The "soom" may be removed from the surface of the pots by a sharpened label, the flat end formed into a wedge. There is always some insoluble parts resulting of burnt soot or ash, but these may be avoided by placing the soot in a hair bag or stocking. Soot water will keep over a lengthened period, but is best fresh.

**THUJA LOBBII—SOWING HOLLY BERRIES (W. C.).**—The seeds in the cones of *Thuja Lobbi* are abortive. The Holly berries kept two years in sand may be sown any time between now and March. We should sow in November.

**DAHLIAS FOR EXHIBITION (B. B.).**—The best twenty-four show and twelve fancy *Dahlia*s are the following:—*Show*: Barnard, Royal Purple, Samuel Plimsoll, Acme of Perfection, Arbitrator, Charles Turner, Cremorne, George Goodall, Herbert Turner, James Cocker, James Service, John Dunnington, John Standish, Julia Wyatt, Lady Gladys Herbert, Leah, Mrs. Boston, Mrs. Henshaw, John Bennett, Prince Arthur, Thomas Goodwin, William Pringle Laird, Yellow Standard, Tison d'Or. *Fancy varieties*: Mrs. Standish, Henry Glasscock, Dolly Varden, Ebor, Egyptian Prince, Flossie Williams, Grand Sultan, Laura Haslam, Miss Lilly Large, Mrs. Saunders, Pauline, and Rev. J. B. M. Camm. Transplant your *Roses* in November.

**SEEDLING FUCHSIA (Darlingtonian).**—Its semi-double sepals are uncommon, but the beauty of the flower is not improved by them.

**LIMING A GARDEN (Arturus).**—Now and in the spring lime should be applied in the evening to destroy slugs. Put on the lime, and add stable manure the next morning. Make the surface of the ground quite white with the lime. Peruse Mr. Abbey's article on "Lime and its Application" in No. 795, the issue of June 22nd of the present year.

**PLANTING CLEMATIS (S. W.).**—The best time to plant is in March, though by purchasing now it is likely you may secure better plants. They may be wintered with the pots plunged in ashes in a frame or in a sheltered situation outdoors.

**HARDINESS OF CAMPANULA CALYCANthemA (Idem).**—These varieties of Canterbury Bells are perfectly hardy, requiring a rather light well-drained soil.

**WINTERING SEEDLING PANSIES, &c. (A Reader).**—Your position being bleak we should prick the Pansies out on a sheltered border in a rather light well-drained soil, and plant them in spring where they are required to flower. The "Cillies," which we presume are Carnations, Sweet Williams, &c., plant now where they are to flower, or they may be planted in spring, moving them with balls.

**SILENE PENDULA COMPACTA (C. Y.).**—It is perfectly hardy, especially in a "moderately light and dry" soil. Plant out in October where intended to flower.

**TRANSPLANTING ROSES ON MANETTI (Idem).**—Take them up carefully in November or early in December, and if they have to be removed a distance wrap the roots in straw and mats to keep them from the air and frosts. Plant as deeply as before and mulch well. Defer pruning until late, and cut back rather closely. They will afford good blooms.

**EUCALYPTUS GLOBULUS (Old Subscriber).**—There is considerable difference between the winters of Italy and those of England. In this country it does not succeed as a hardy tree except in a very warm situation and dry, so that the growths made are well ripened. We have seen it thriving in a cold house. It requires a moist situation, and a wall with protection, or a greenhouse.

**REMOVING WATER FROM SOIL (W.).**—Nothing will do so so efficiently as drainage, the want of which we presume is the cause of your soil not being dry. If the ground, however, does not suffer from stagnant water, the staple of the soil may be improved by an admixture of old mortar rubbish and ashes. November is the best time to transplant *Roses*, or as soon as possible after a majority of their leaves have fallen.

**RETAINING THE AUTUMN TINTS OF LEAVES (B. Hindley).**—It can only be done, so far as we are aware, by drying the leaves between sheets of blotting paper, changing them to dry sheets daily. The sheets should be dry and pressed firmly, and relaxing the pressure after the leaves cease to moisten the paper, placing them thinly between sheets of paper afterwards.

**PEAR EATEN (Idem).**—The Pear has the appearance of being eaten by wasps, bluebottle flies probably assisting. It is probable that birds may have begun the mischief by pecking at the fruit, complete devastation being effected by the wasps.

**FUNGUS ON LAWN (S. M. H.).**—Sow common salt over it when the fungi appear at the rate of ten bushels per acre.

**ARRANGEMENT OF FRUIT ROOM (Constant Reader).**—The walls are sufficiently thick. We advise you to skirt the wall with boards, and plaster the roof as you propose. The floor, we think, will answer as it is. If you find the damp injures the fruit then you can lay down boards.

**NAMES OF PLANTS (T. S.).**—*Acanthus spinosus*, Prickly *Acanthus*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### CAN A POULTRY FARM PAY?—No. 1.

THIS question has been fully answered in the affirmative by our neighbours the French. Hitherto with us the attempts have ended more or less in failure; but is that a reason, if a proper method is adopted and due care and supervision exercised, that we should not succeed in the future? From the accounts I have before me of the French poultry farms I gather that if we follow their example and breed for sale, just as ordinary farmers do their sheep and oxen, there is no apparent reason why a fairly remunerative profit should not be realised by poultry farmers in this country. My belief is that all attempts hitherto in Great Britain have been undertaken and carried out on fallacious bases. The mania for prize-winning and fancy exhibiting has helped to bar success. Again, too expensive and elaborate buildings, &c., have been another cause of failure. Look to some of our most successful breeders: ordinary wooden houses have been enough for them, and their birds have everywhere gained commendation. Let, therefore, economy and real, not elaborate, efficiency be our aim.

1st, Let there be plenty of space in the open runs. The poultry will find for themselves much good and wholesome natural food, and so save extra feeding. 2nd, Let the home feeding be regular and liberal, but not excessive; your birds then will always be in good health and condition. 3rd, Whether you purpose producing eggs or meat for the table, choose suitable breeds for each object. Do not, however, use too many different breeds, as that involves complications in your houses, yards, and accommodation generally. 4th, Let your personal supervision be constant, and employ only the best and most trustworthy assistants.

I have lately read with pleasure in Mr. L. Wright's book on poultry of the Bellair (French) farm, that if intending poultry farmers here took this as their model, and only improved upon it so far as their own experience and that of celebrated poultry breeders suggested, they would soon have a sound system to work on and success be assured.

To take another line of argument. A farm, say, of fifteen or twenty acres will only support a certain number of sheep or oxen according to its fertility of soil; all other feeding stuff, oil cake, &c., will have to be paid for extra, and that in high proportion. Calculate out the product of this in beef and mutton for the market. So many oxen or sheep of such and such weight can be raised, but what can we say of poultry? In this case so much does not depend on the quality and richness of soil; and a greater weight of poultry at less cost, as I purpose showing in my next article, will be raised than could be of beef or mutton.

Poultry, it is true, are liable to disease, so are sheep and oxen. With twenty acres, too, if properly managed nearly every requisite might be raised for the stock kept. Could this be done in ordinary farming? Byes, cattle-steading, granaries, would in the case of an ordinary farm be on a much larger and more expensive scale than need be for a poultry farm.

There is only one question that seems to me of vital importance now left for consideration—Is there a good and conveniently situated market for your poultry, easy of access, and where fair wholesale prices can be obtained? If so, I can see no reason to doubt success.

I have for the last eight or ten years raised poultry in a large way for my own consumption (selling only at times the surplus), frequently having three or four hundred birds young and old in my yards, and averaging over five thousand eggs per annum, with always a fair supply during winter from young pullets. The direct gain in money was comparatively small, inasmuch as my runs were contracted, so entailing extra feeding, and little produce went to market, and that not of the best description; but indirectly my butcher's book was greatly relieved, and I always had a pleasant variety of food for the table. I bred Houdans, Brahmas, Chinese and common Geese, Peruvian and common Ducks.

As to the question of breeding for actual profit, I have not hitherto tried it; but so convinced am I from my past experience as an amateur that it will or should pay that I intend shortly, in conjunction with a friend of mine, to undertake poultry farming on a fairly large scale, beginning moderately at first, and eventually, if successful, extending our sphere of action.

So far I have given you and your readers my ideas and experience, hoping that others will take up this question and give us the benefit of their advice: in any case they must look upon the question in the proper light—viz., profit and loss.—G. R. HARRIOTT, *Killmore*.

**NOTTINGHAM POULTRY AND PIGEON SHOW.**—The Dog, Cat, and Poultry Show to be held at Nottingham in October, is not under

the auspices of the Committee of the Nottingham Poultry Show, which, we believe, will be held towards the end of the year.

### NORTHALLERTON POULTRY SHOW.

THE annual meeting of the Northallerton Agricultural Society came off on the 22nd inst., when the entries were greatly in advance of those of any previous year. Some capital pens were provided, and protected with canvas and placed in the open air. The day was very fine, so that the poultry did not suffer from exposure.

*Dorkings* are largely kept in the locality, and the class was a very good one, old birds carrying off the first and chickens the second prizes. *Game* were also a fair lot; first old Brown Reds, and second chickens of that variety. *Cochins*, very good old birds being ahead here also, the cup for best pen going to these. *Brahmas* not good, but there were some moderate *Polish*. Most of the *Hamburgs* were out of feather, but the first-prize winners were well-known birds of high quality. *Bantams* poor except the winners in the Variety class; first Silver Sebrights, and second Blacks in deep moult. *Ducks* very good in all classes. The first in the Variety class a neat pair of East Indian. *Turkeys* were a grand lot, and *Geese* also good.

In *Pigeons* the first-prize Carriers were very promising young birds, and the Pouters were good as a class; first Black, and second Blue Pied. In *Jacobins* first and second Reds, good in all points; rest only moderate. In *Tumblers* was a pair of young Almonds, cock very promising. *Fantails* a good class, but the wind used them ill, and made them difficult to judge. *Turbits* also a fair lot of thirteen pens; first Blue and second Reds. *Magpies* all Blacks, very good throughout, but the pick of the Show was a pair of White African Owls in the Variety class, which were a really grand pair, and very much like the cup-winners at Middleton-in-Teesdale.

POULTRY.—*DORKINGS*.—1, J. White. 2, A. Jackson. *GAME*.—1, W. Young-husband. 2, W. Bearpark. *SPANISH*.—1, H. Dale. 2, J. Robson. *COCHINS*.—1, G. H. Proctor. 2, C. Sidgwick. *BRAHMAS*.—1, J. Cass. 2, T. P. Carver. *POLANDS*.—1 and 2, T. P. Carver. *HAMBURGS*.—*Gold-spangled*.—1, T. P. Carver. 2, J. Johnson. *Silver-spangled*.—1 and 2, W. Bearpark. *COCK-PENCILLED*.—1, T. P. Carver. 2, G. Kidson. *ANY OTHER VARIETY*.—1, T. P. Carver. 2, Col. Cathcart. *BANTAMS*.—*Game*.—1 and 2, G. Carter. *Any other variety*.—1, T. P. Carver. 2, R. H. Ashton. *DUCKS*.—*Rouen*.—1, G. Pounder. 2, Mrs. Booth. *AYLESBURY*.—1, J. Cass. 2, T. Scooby. *Any other variety*.—1, G. Sadler. 2, R. H. Ashton. *TURKEYS*.—1, T. P. Carver. 2, T. Parker. *GEESE*.—1, J. Arrowsmith. 2, R. Brown. *SELLING CLASS*.—1, G. Carter. 2, G. Pounder. *LOCAL CLASS*.—*Barndoor Fowls*.—1, G. W. Dale. 2, G. Granger. 3, G. Oliver. *PIGEONS*.—*Carriers*.—1, T. C. Taylor. 2, J. L. Nicholson. *POTTERS*.—1 and 2, G. Sadler. *JACOBINS*.—1, J. H. Bennison. 2, J. L. Nicholson. *TUMBLERS*.—1, T. Horsman, jun. 2, J. L. Nicholson. *FANTAILS*.—1, G. Sadler. 2, J. L. Nicholson. *TRUMPETERS*.—1, G. Sadler. 2, J. Petch. *TURBITS*.—1, J. L. Nicholson. 2, Wetherill & Braithwaite. *NUNS*.—1, H. Mitchell. 2, Wetherill and Braithwaite. *MAGPIES*.—1, G. Sadler. 2, J. L. Nicholson. *ANY OTHER VARIETY*.—1, J. H. Bennison. 2, W. S. Clark. *SELLING CLASS*.—1, J. Maude. 2, H. S. Horn. *RABBITS*.—*ANY VARIETY*.—*Buck*.—1, A. Robson. 2, W. Tessiman. *Doe*.—1, A. Robson. 2, J. Johnson.

JUDGE.—Mr. E. Hutton, Pudsey.

### AYLESBURY POULTRY SHOW.

THIS Show was held on the 20th inst., and the quality was, as usual, very good. We hope the Committee will arrange some of their classes better another year, for in a Variety class of seventeen pens of splendid birds there were only two prizes, and one of those went to Bantams.

There were sixteen pens of *Dorkings*, and the cup again went to Silvers, the winners here being a very good pair of chickens, good in size, colour, and claws. We liked pen 7 (Beachey) very much indeed; they were a good pair of Coloured. The Silver pullet, too, in Lady Dartmouth's pen was a pretty bird. In Dark *Brahmas* the cup pullet was very lovely, her pencillings being superb. In Lights Mr. Dean won first with a good pen of old birds. We thought he had retired permanently, and had sold all his stock to Mr. Hall. Second and third prizes were won by Light chickens of good quality. *Cochins* came well to the front, and a very well-shaped pair of adults won the cup. The second were a good pair too, the cockerel being the unnoticed bird of Mr. Darby's at Southport, with a very fine adult hen. Good Partridge chickens won first in their class, and a very good pen of Blacks took third place, old Partridges coming in the middle. *Spanish* were a superior lot, though not a large collection. The cup pen was a first-class pair. In the *Game* we noticed nothing very striking. The cup went to good Brown Reds, Black Red chickens taking second, while in the next class a neat pair of Duckwing chickens won first. The *French* mustered very well. The cup Houdans were a good pair and large in size, while in Crêves a very fine old pen took the cup. Many of the highly commended pens were good, and well worthy of prizes. In *Hamburgs* the silver cream-jog, which Messrs. Field & Son annually offer for competition at this Show, went to Trentham for a pen of Golden-pencils, Silvers of good quality from the same yards taking second place. In Spangled *Hamburgs* the first went to good Silvers, while Silvers also took second, the pullets in both pens being well spangled and rich in markings. *Leghorns* made two very fair

classes; Whites were perhaps the best, the first and second here being very even in quality. We still find badly-coloured earlobes and high tails in the Browns, and hope they will soon be remedied by the enthusiastic members of the Leghorn Club. Mr. Ayre's two pullets were both very good indeed. The Variety class was, perhaps, one of the best classes in the Show. A very beautiful pen of White-crested Blacks won first, and well they deserved it. The cockerel is of much promise, but is not the same bird Mr. Norwood won with at Bath and Weymouth, we believe. Second prize went to lovely Silver-laced Bantams. Another half-dozen pens well deserved prizes, notably so Mr. Darby's Black Poles, Mr. Burrell's Golden ditto, and Lady Dartmouth's Silver ditto. *Aylesbury Ducks* were very fine, and quite properly Mr. Fowler won. Rouens too were admirable, and the cup pen really enormous. A very large pen of Ducklings took second place. *Geese* made but a poor collection for numbers, and *Turkeys* "were not." The Sale classes were well filled with mostly but fair specimens. Mr. Hewitt awarded the prizes. The whole Show seemed well managed as usual, and the catalogue arrangements were as admirable and prompt as ever.

POULTRY.—*DORKINGS*.—Coloured.—1, T. C. Burnell. 2, J. Walker. 3, H. Dadds. *Any other variety*.—Cup, T. C. Burnell. 2, E. Woodford. 3, O. E. Cresswell. *BRAHMAS*.—Dark.—1 and 2, S. Newham & Manby. 3, R. P. Percival. *Any other variety*.—Light.—1, T. A. Dean. 2, R. P. Percival. 3, P. Haines. *SPANISH*.—1, W. R. Bull. 2, Mrs. Alsop. 3, S. L. Edwards. *COCHINS*.—*Buff*.—Cup, P. Ogilvie. 2, A. Darby. 3, Mrs. A. Tindal. *Any other variety*.—1, S. R. Harris. 2, J. K. Fowler. *Partridge or Black*.—1 and 2, Mrs. A. Tindal. 3, A. Darby. *GAME*.—Black-breasted or other Red.—Cup, J. Cock. 2, S. Matthews. 3, E. Holland. *Any other variety*.—1, S. Matthews. 2, Miss F. K. Winwood. 3, G. H. Fitz-Herbert. *HOUDANS*.—Cup, S. W. Thomas. 2, Mrs. Vallance. 3, E. Harvey. *CREVE-CEURS*.—Cup, F. F. Le Sueur. 1, Mrs. A. Tindal. 2, E. Burrell. 3, Rev. H. R. Peel. *HAMBURGS*.—*Gold or Silver-pencilled*.—1, Duke of Sutherland. 2, J. G. G. 3, T. Dean. *LEGHORNS*.—*White*.—Cup and 2, R. R. Fowler. 3, C. C. Seaman. *Brown*.—1, E. Ayre. 2, R. Harvey. 3, A. Kitchen. *GAME BANTAMS*.—1, F. C. Davis. 2, Miss W. Wyles. *ANY OTHER VARIETY*.—1, T. Norwood (Black Polands). 2, M. Leno (Laced Bantams). *DUCKS*.—*Aylesbury*.—Cup and 2, J. K. Fowler. 3, J. Hedges. *Rouen*.—Cup and 2, S. W. Evans. 3, J. ### CHESTERFIELD POULTRY SHOW.

THIS, the first Show of poultry, was held in connection with the Norton Farmer's Club on the 20th inst. Turner's pens were used, and a capital marquee was provided; and with Mr. G. Helliwell as manager the whole arrangements were well carried out. The birds were of any age, which we think a mistake, as the entries would have been large had it been a chicken show. There were 187 pens.

*Brahmas*, first-and-cup a massive pen of old birds in fair order; second also old, but not in good feather, but cock good in shape. *Brahmas*, Light a fair lot as regards the winners. *Dorkings*, first and second chickens, and third old, the latter best except that the cock had one badly swollen foot. *Cochins* a grand lot; first-and-cup a pair of very large Buffs, grand in colour but little dark in tail; second and third Buff chickens, also very good. *Malays* were chickens, but not forward. *Hamburgs* being mixed classes were not large entries, the cup going to a pen of Silver-pencils, which were something near faultless; the second were Gold-pencils, very bright-looking, the cockerel perfect except that the spike of comb is not level at the base with the comb, and the pullet a little coarse in pencilling. Spangles only two, were fairly in the race; first Gold and second Silvers, and both out of feather. *Spanish* won the cup; *Polish* and *French* fowls being good and in very good order. *Game*, Black Reds were a large class, but there were many faulty birds; first-and-cup a good all-round pen of chickens; second lost in very few points, but were old and out of order; third also good. *Duckwings*, first cock a grand-coloured bird, but pullet not so good in colour; second a wild-looking fellow, good pullet; third best pullet, but cockerel crooked in breast. *Piles*, first an old cock and pullet, very good, the cock especially, and to this was awarded the extra for best cock in the Show. Brown Reds poor except first and second; no third given. *Bantams*, Black Red Game a good large class; first as near perfect in all points as possible, and the cup was given here, the rest of the birds also coming up well in quality. Brown Reds a moderate lot, the first in full feather. *Duckwings* poor, but *Piles* very good. In the Variety class the winners were Blacks, first very good chickens. In the Variety class all the winners were Black *Hamburgs*; first a good all-round pen; second also good, but cockerel not so good as first; third by far the best cockerel, but pullet no match at all, quite a chicken, and not fit for the show pen. *Geese* about the best class in the Show, and two extra prizes were awarded. There were some good birds in the Variety class, and some of these changed hands.

POULTRY.—*BRAHMAS*.—Dark.—1 and Cup, J. F. Smith. 2, J. Long. 3, E. Pritchard. *Light*.—1, E. Snell. 2, G. B. C. Breeze. 3, F. Holbrook. *DORKINGS*.—1, E. Snell. 2, W. Moritt. 3, W. Arkwright. *COCHINS*.—1 and Cup, H. Robinson. 2, C. Sidgwick. 3, J. F. Hodson. *MALAYS*.—1, A. Brooke. 2, R. Hawkins. *HAMBURGS*.—*Gold and Silver-pencilled*.—1, E. Beldon. 2, J. Long. *Gold and Silver-spangled*.—1 and 2, H. Beldon. 3, S. W. Hallam. *SPANISH*.—1 and Cup, R. Newbitt. 2, H. Beldon. 3, J. Powell. *POLANDS*.—1, H. Beldon. 2, A. & W. H. Silvester. 3, A. Darby. *FRENCH*.—1, E. Snell. 2, J. E. Clayton.

3, B. Barker. GAME.—*Black Red*.—1 and Cup, J. Fletcher. 2, J. S. Hodgson. 3, A. Brooks. *Duckwing*.—1, H. E. Martin. 2, J. Cook. 3, J. Calladine. *Pile*.—1, J. F. Walton. 2, G. Barnesby. 3, P. Lucas. *Brown Red*.—1, J. Cook. 2, W. Berestford. *Any other variety*.—1, J. Cook. BANTAMS.—*Black Red*.—1 and Cup, E. Walton. 2, H. Walshaw. 3, J. Oscroft. *Brown Red*.—1, W. H. Robinson. 2, J. Fletcher. 3, J. Mayo. *Duckwing*.—1, W. L. Mason. 2, R. Newbitt. 3, J. Atkinson. *Pile*.—1, E. Walton. 2, W. Roe. 3, J. Oscroft. *Any variety*.—1, E. Walton. 2, R. H. Ashton. 3, R. Wingfield. ANY OTHER VARIETY.—1, C. Sidgwick. 2, A. S. Webb. 3, J. Long. *GEES*.—1 and Cup, H. Beldon. 2, E. Snell. 3, F. G. S. Brown. *Extra*.—1, E. Snell. 2, P. Wood. *TURKEYS*.—1, E. Snell. 2, J. Martin. *DUCKS*.—1, E. Snell. 2, A. & W. H. Silvester. 3, J. Denton. *SELLING CLASS*.—*Cock*.—1, A. & W. H. Silvester. 2 and 3, W. A. F. Fenwick. *Hen*.—1, E. S. Milnes. 2, A. Darby. 3, J. N. Lawson.

JUDGE.—Mr. E. Hutton.

### CRYSTAL PALACE POULTRY SHOW.

MAY I again, as in former years, ask through your columns for subscriptions towards a five-guinea cup for the best adult Silver-Gray Dorking cock or hen at the forthcoming Crystal Palace Show? It will save me much trouble if subscribers are kind enough at once to send me their donations without my writing to them personally.

I also am trying to collect £2, the first-prize money for an Archangel class, upon which condition a class will be given to that beautiful but neglected variety of Pigeons.—O. E. CRESSWELL, *Early Wood, Bagshot*.

### INFLUENCE OF EXTERNAL CONDITIONS ON PIGEONS' FORM.

TAKE two families of the same strain of Pouters, all average birds, place one family in a large roomy loft, where they can have plenty of action, feed them with the best of food, keep them moderately warm all the year (temperate climate), and the tendency is to increase in size and beauty, and with judicious selection of the best specimen, a first-class strain is formed. The other family is placed in a low small pen, exposed to the inclemencies of the weather, and fed on refuse, and (notwithstanding selection) is, in a few seasons, unrecognisable as being of the same strain with the well-protected family. With Carriers and Runts the same influences make or mar the strains. Therefore all the birds having size as a point must be well nursed, and especially is it necessary while they are nestlings. Keep them warm, and force them with feed. When breeding Pouters and Carriers, the difference between the summer and winter birds was so great that I stopped breeding them during the winter (until I heated my lofts), and during the breeding season, after a number of experiments, feed mostly on black-eyed peas, my best birds being forced by that easily-digested food.

By strict attention in placing these three varieties under the three influences of heat, food, and room, especially while young, one can increase the size (form) in a comparatively short time; while under the adverse circumstances of cold, &c., the form is likewise changed, but rather unsatisfactorily.

In a very short time a very perceptible change of form is discovered in Pouters that are obliged to enter low boxes; the continuous stooping elongates the back, and a pair of short-backed birds will become roach-backed, impressing that fault upon their young, which, being bred in low boxes, will never be anything else. Many a good strain of Pouters has degenerated under such external circumstances, much to the disgust of the owners. So have Carriers lost the bold upright carriage by dodging into low boxes—some of my own among them.

Suppose that instead of large we wished to obtain small size. Expose the individuals to adverse external conditions. This was vividly impressed upon me while breeding the ordinary Speckled Flying Tumbler. One very cold winter there was but one bird escaped the inclemencies of the season; it was a grizzled hen very much stunted by the cold; several times it was revived from a stiffened condition by placing it near the stove without any anticipation of its recovery; it did survive, however, though always very small and delicate. It mated the following season, and after raising two or three sets of young, died egg-bound. From the young I obtained many very beautiful specimens no larger than the Almonds.

I extended the principle to Fantails, purposely exposing them to the cold, and obtained some very beautiful birds; and I think that exposure to cold while young has some influence upon the nervous system of the Fantail in increasing the vibration of neck, as the birds so exposed had the trait to higher degree than others of the same strain.

These examples are sufficient to suggest to the reader the influence of climate, while in almost every nest of moderate feeders one of the young birds is neglected, becoming stunted for want of food, thereby illustrating, side by side with its more fortunate companion, the influence of food upon change of form.

Pigeons have occupations as well as men; or rather we should say actions productive of change of form. Every action of muscle changes form—of itself, and of the objects to which it is attached. In its minor degrees this change is imperceptible to the senses, but when it is continued for a period of time

it is more and more observable. A horse is taken from the field, thin-legged, big-bellied, with flabby and slight enduring muscles, and put in the hands of a trainer; within a few months it is difficult to recognise in the firm, compact animal, with its rolls of muscles vibrating between the glossy hide, the raw material culled from the field. Change of condition has changed the form. So of Tumblers; keep them housed, and the muscles are thin, the shoulders narrow, and flight exhausting. Fly the same birds hard; the shoulders broaden, muscles are felt like bands of steel, and hours of flight are endured. The form is changed by the conditions. As with Tumblers, so with all birds of flight.

Feathered feet is a condition that changes form. Birds with such appendages bring into more determined action certain muscles necessary to drag the feathers through or over impediments, and their influences broaden the pelvis and flatten the back, as is seen in Booted Swallows and Trumpeters. Thus it is seen that the conditions of food and climate produce size, and occupation or action unceasingly change it, and, being under the control of man, place in his hands the power of moulding forms to his wish.—DR. W. P. MORGAN (in *American Poultry Bulletin*).

At a general meeting of the Central Norfolk Poultry Club, held at the Royal Hotel, Norwich, on Saturday, 9th September inst., the Rev. T. S. Fellowes in the chair, it was proposed and unanimously carried that the next show be held on Wednesday and Thursday, 3rd and 4th January, 1877, and that in addition to poultry and Pigeons the show should be open for the exhibition of Canaries.

### BRITISH BEE-KEEPERS' ASSOCIATION.

ALEXANDRA PALACE HONEY SHOW, SEPT. 15TH, 16TH, AND 18TH.

CONTINUING our report of last week we now come to the honey, of which the show was very fine. For the second time the Association offered prizes for the largest and best harvest of honey in the comb from one stock of bees under any system or combination of systems. It was hoped that competitors using Mr. Pettigrew's large skeps would have come forward here, but such was not the case. Although Mr. Phillips gained the second prize for a harvest of 131½ lbs. in eight small supers from a small straw hive, their quality was, however, exceeded by two supers holding 120 lbs. of fine comb, exhibited by Mr. Cowan from a thirteen-frame Woodbury hive. These two exhibits were notable examples of the two systems—wood *versus* straw, and it would be interesting if Mr. Cowan and Mr. Phillips would furnish to our columns a short detailed statement of their respective managements. The Rev. G. Rayner's super, weighing 67 lbs., excelled in purity of colour either of the above, and had it been heavier would have deserved a better place than third, which it obtained. In the next class, for the best exhibition of super honey from one apiary, Messrs. Cowan and Phillips again held first and second places, the third prize going to a cottager, Mr. Walton, who was a winner in eight other honey classes—very creditable to his skill in management of his bees. In the class for straw supers Mr. Phillips took first prize with 26½ lbs., a weight which would have been nowhere in wood or glass. If we except Mr. Phillips' exhibits the show from straw hives was very poor indeed, and there can be no question that they have no chance under equal conditions with the others. We may safely say, in the south of England at least, the day of straw hives is past for those bee-keepers who go with the times.

The remaining class for wood and composite supers was well filled, boxes of upwards of 40 lbs. being quite common, the first prize going to Mr. Walton for 75 lbs. of very fine comb. Sectional supers for the first time at any show made a creditable appearance, Mr. Cowan again taking the lead with first and second prizes—one exhibit in wood, the other in tin boxes. This is a step in the right direction—i.e., to obtain fine honeycomb in a saleable form. All that the retailer has to do when selling is to wrap up the section in paper, and without waste or mess this can be done. The cost of these sections very neatly made, as exhibited by Mr. Lee and others, is under 2d. each.

The first-prize glass super was a grand one—a noble vase in the shape of an oriental oil jar well filled with 101 lbs. of honeycomb; the colour of the comb was not fine, not by any means equal to its neighbour, a globe containing 50 lbs. of exquisitely white comb, to which was awarded the second prize. The production of such supers as these may be very well for show purposes, like over-fat cattle for Christmas, but for useful purposes they are not desirable. In these two instances the bees had certainly neatly filled the glasses, but they could only be emptied by cutting and scooping the honeycomb out. What retailer would or could profitably do this, and what private person would care to see a 100-lb. glass of honey appear again and again on his breakfast table until consumed?

The exhibition of run and extracted honey was not large, and not in all cases of good quality. An attractive show of clarified honey was made by the Rev. J. G. H. Hill in small narrow

glasses, but, as the conditions of the class required not less than 5 lbs. in each class, no prize could be awarded. By far the neatest and most striking exhibit was that made by the Hon. and Rev. H. Bligh, who was honest enough to enter it "not for competition," as much of the comb was made last season by the bees. The display consisted of three glass and wood supers, flanked on each side by a pile of sections, with glasses of run and extracted honey in the foreground, the various methods of harvesting being thus brought together; the weight of the whole exceeded 100 lbs. from the single stock of bees.

It is evident that cottagers are not yet, as a body, educated for honey shows, for the Association again offered seventeen prizes in three classes, for which only eleven men competed; even this is better than in previous years, but it is very discouraging to the Committee. There were some very excellent supers shown, which need not have been in cottagers' classes to have taken prizes.

It is unfortunate that the Association cannot hold their Show earlier in the year, before the aristocracy leave town, for such only are buyers of first-class honey; and it cannot be denied that, as a "honey fair," the Exhibition was a failure, nearly all the fine supers having either been sold to the dealers at a sacrifice, or returned to their owners.

DRIVING BEES VERSUS SMOTHERING.

On Thursday night September 14th a farmer about a quarter of a mile distant was about to "put down," as he stated, his bees by the cruel fashion of brimstoning. He had six skeps, which he would have operated upon unless I had interceded for the lives of the bees and prevailed upon him to allow me to drive them, according to Mr. Pettigrew's instructions, into empty hives. I set to work about eleven o'clock, and about one o'clock accomplished the task successfully. After sunset I had the skep carried up to my garden, where I joined two stocks together in a large-sized hive, and also added one to a stock which was weak. I have been feeding every night since with a pound of syrup. The bees are very strong. How long shall I continue to feed?

In two hives small pieces of comb gave way, which I removed. It was of a very soft thin texture and very white. The syrup was placed in a soup plate covered with blue foolscap paper with holes bored in it. I found the bees devoured it to such an extent that I have replaced it with brown paper, which they do not like as well. I have seen stated that paper is a good thing to place upon the board of a super. I did so in one case, and found when removing the super that the bees had eaten the brown paper and built combs on the board. I may state, that in driving the bees and joining them I never troubled myself about the queens.—S. A. BRENNAN, *Cloghan Rock, Co. Tyrone.*

BEDFORDSHIRE BEE-KEEPING.

I BEGAN bee-keeping last year in August with one stock hive, which I bought of a labouring man. It was a small hive, and did not weigh more than 25 lbs. I fed the bees a little rather late in the season, and they managed to live through the winter. On the 28th of May they swarmed but did not settle, and went back; the next day they swarmed and settled on a little elm tree, but just as I was going to live them they all went back; the next day they swarmed on the wall close by, but went back as before. On the 2nd of June they swarmed on a raspberry cane; I lived them and set them up all right, and put on a super that held 7 lbs. Four days afterwards the old hive cast a second swarm, so I then had three hives. Last month I bought two more good early swarms, but they were in small hives. My second swarm was in a very ill-shaped hive, so I thought I would try what I could do by driving. I smoked the hive a little with fustian rags, turned it up, and put another hive over it, wrapt a cloth round the junction, and began hammering, but owing to the bad shape of the hive many of the bees came out, but I drove most of them into the empty hive. I took the honey out, but the next morning when I came to turn the hive up there was not one bee in it; they had evidently gone to one of the other hives.

Two or three weeks ago I wrote to Mr. Pettigrew to ask him where I could obtain large hives; he very kindly gave me the address of Mr. Yates, 16 and 18, Old Millgate, Manchester. I wrote to him for a catalogue of his hives and prices; he sent me the catalogue, and I sent for eight of Mr. Pettigrew's 18-by-12-inch hives, four of his 20-by-12-inch hives, two ekes for each size, a pair of honeycomb knives, and two Lancashire bee-feeders. I have them, and am very much pleased with them. Some of the people about here say, "Have you seen Mr. Baker's great bee hives?" and three or four people have come up to see them. Yesterday I weighed my hives. One of the two that I bought weighed 30 lbs., the other 39; my first swarm 32 lbs., and the old stock 33 lbs. I have now my two Lancashire feeders on the two lightest, and mean to try to feed them all up to 40 lbs. weight each. I have taught two or three people how to drive bees instead of using the brimstone pit, and hope to teach

them to use large instead of small hives.—A. DE C. BAKER, *Old Warden, Beds.*

OUR LETTER BOX.

TUMOUR IN COCKEREL (*J. A. B.*).—It probably occasioned the leg-weakness, and, indeed, general debility, as such tumours usually do.

ADDRESS.—Mr. H. Attwood, Wenlock Street, Luton, Beds.

CHEAP BEE-KEEPER'S MANUAL (*J. F.*).—The best and cheapest book on bees is "Bee-keeping for the Many," published at our office for 4d., by post 5d.

COMBS OF YEARS OLD (*Idem*).—Bees may be kept in the same comb and hive for many years. The former will remain good for ten years, but the bees bred in them will by that time have become somewhat diminutive. We should destroy the comb after six or seven years. Hives will keep good if properly protected almost any number of years, especially if made of wood.

EMPTY DRONE COMBS (*T. W. W. Kinlay*).—The combs of which you write are not in any way injured by the sulphurous fumes, and are very eligible for super work. Place them neatly in a small super on a hive containing a swarm of bees, and let them have honey enough to fill the combs as fast as they can carry it up. We shall be pleased to have the result of your experiment for publication. At this late season we are of opinion that the combs would be sooner filled on an empty hive than on one nearly full.

REMARKS.

20th.—Rather hazy and dark morning and evening, but a pleasant day.  
21st.—Hazy morning, but followed by a beautifully fine day, rich sunset, and starlit night.  
22nd.—Fine morning and splendid day throughout, slight rain commencing at midnight.  
23rd.—Rainy morning and forenoon, but fine afterwards.  
24th.—Rainy and very dark all day, except from noon to about 3 P.M.  
25th.—Fine morning, high wind during the night and till the after part of the day.  
26th.—Dark damp morning; rainy till noon.  
Temperature rather warmer than during the previous fortnight, and much damper.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 27.

LARGE quantities of Grapes are still arriving from the Channel Islands, and the price of second-rate home-grown fruit remains low. There is still a fair supply of Apples at last week's quotations; while Pears, consisting of Marie Louise, Louise Bonne of Jersey, and Duchesse d'Angoulême, are sought after at higher rates. Kentish Cobs are lower in price.

From observations taken near London during forty-three years, the average day temperature of the week is 61.6°; and its night temperature 42.4°.

## CULTURE OF HYACINTHS AND OTHER SPRING BULBS.

URSERYMEN and seedsmen are now busy executing orders for these spring-flowering bulbs, and those intending to purchase should not delay any longer. When the bulbs arrive they ought to be placed in a dry position. They are usually packed in buckwheat chaff, and in a damp close place this becomes musty and causes decay in the bulbs. Early in September is the best time to pot Hyacinths for early flowering. Another potting should take place about the first week in October, and those intended to flower very late should be potted the last week in October or the first week in November. There is not much difference of opinion amongst the best growers as to the proper constituents of the potting material; good sandy loam, leaf soil, decayed cow manure, and river sand make a suitable compost. If the loam is clayey it is not well adapted for the culture of Hyacinths, but if a larger proportion of sand is added to it, it will greatly improve the compost. Six-inch pots are the best for the late-flowering sorts, and 5-inch are sufficiently large for those bulbs that are forced early.

A few words may be written as to the manner of potting. A very usual way is to fill the pot loosely with the compost, place the bulb with its base on the surface and then press the bulb down to a sufficient depth; this is wrong in practice, though it may seem right in theory. Bulbs potted in that way are often thrown out of the soil altogether, because the roots fail to penetrate into the hard material underneath. The proper way is to make a hole with the fingers for the bulb, and then in potting press the soil firmly round it. A little sand placed in the hole first is desirable.

The best position for the bulbs after they are potted is out of doors. The pots should be placed on a hard bottom of coal ashes, or some material through which worms will not care to force a passage. I generally cover the pots to a depth of 3 or 4 inches with cocoa-nut fibre refuse, and there they are left until it is time to remove them under glass. Coal ashes are not good to plunge them in, often causing decay in the flower spikes.

Many persons think that the best place to put the Hyacinths in after they are potted is under the stage of the greenhouse; this is a great mistake, a worse position could scarcely be found for them. Those pots that are placed underneath where water drains from the pots on the stage become sodden with water and the soil becomes sour; others receive none and suffer from drought, and for other reasons this place ought not to be chosen for them.

Sometimes it is necessary to retard the roots, and this I have seen done in a way that was not commendable. They were left in the plunging material until the end of February or the first week in March, and the plants had grown nearly 6 inches, having much the appearance of blanched Seakale. The leaves and flower spikes soon

became green by exposure to the light, but a check was experienced from which the plants never recovered. When the plants are intended for very late flowering they ought to be removed to a cold frame behind a north wall early in January, and the pots may be plunged to prevent injury from frost. Those who grow for exhibition will also be careful to remove their stock to a cold frame or pit at the same time.

By the 1st of January the bulbs have started to grow upward and the pots are fairly well-filled with roots, and on their removal to the cold frame or pit a small pot should be inverted over the crown for a few days, as the sudden change from the cold plunging material to the dry atmosphere of the pit might be injurious to the tender growth. If there are no other plants in the frame with the Hyacinths the lights might be kept close for a few days and the glass be covered with mats; this is the most convenient way when large quantities are grown. A heated pit is a more suitable place for them than a cold frame, for the obvious reason that they might in the cold frame be checked in their growth by severe frost, and even if mats are placed over them it is not so well as keeping severe cold from them by hot-water pipes. Plenty of air ought to be admitted even at night if the weather is mild. The flower spikes and foliage are formed very rapidly, and it is a sign of bad cultivation if the leaves do not retain their natural erect position until the spike decays.

Perhaps the best Hyacinths in the world have been exhibited at South Kensington and Regent's Park Botanic Garden, but one very often sees otherwise well-grown examples having the leaves hanging about and tied round the middle with a strip of matting. In many cases this is caused by the Hyacinths being placed in a high temperature to force them in by a certain date. I have known good growers place them in a night temperature of 70°; but this in itself must be called bad management of another kind, as the proper way to force Hyacinths is to place them in a house near the glass with a temperature of not more than 55°, and a chink for air should be left in the ventilators all night. Of course it requires a little experience as to the best time to place them in heat.

Some varieties take much longer than others to arrive at the point nearest perfection. For instance, take two single blues—Baron Von Tuyl and King of the Blues, place them in the forcing house together, and Baron Von Tuyl would be in flower from two to three weeks before the other. Von Schiller, Cavaignac, Vurbaak, single reds, are amongst the latest. Sometimes one bulb will throw up two, three, or more spikes; when this is the case all the inferior spikes should be removed, allowing only the best one to remain—that is, if they are intended for exhibition; if only for decorative purposes in the greenhouse all the spikes may be allowed to remain. When the flowers are fully expanded the plants ought to be kept as cool as possible; plenty of air should be admitted, but they ought not to be exposed to draughts, and during bright sunshine some slight shading ought to be placed over the glass. When Hyacinths are forced very early

it is a good plan to place the pots in a gentle bottom heat, so that the roots are stimulated into action at the same time as the top; this is the more necessary if the plants have to be placed in a high night temperature to begin with. I have grown the Hyacinth very successfully for many years, and the above few remarks contain all the instructions requisite for their culture.

The following list of sorts are those that I grow for exhibition, but they are also the best for ordinary greenhouse culture. The double varieties are marked with a (†).—*Red*: †Duke of Wellington, Fabiola, Garibaldi, Gigantea, †Lord Wellington, †Koh-i-noor, Lord Macaulay, Linnaeus, Prince Albert Victor, Solfaterre, Von Schiller, and Vurbaak. *Blue*: Baron Von Tuyl, Blondin, Charles Dickens, Czar Peter, De Candolle, Feruck Khan, Grand Lilas, General Havelock, King of the Blues, Leonidas, Lord Derby, Laurens Koster, Marie, Mimosa, and †Van Speyk. *Mauve and Purple*: Haydn and Sir Henry Havelock. *White*: Alba Maxima, Baroness Von Tuyl, La Grandesse, L'Innocence, Mont Blanc, and Grandeur à Merveille. *Yellow*: Bird of Paradise and Ida.

Early-flowering Tulips require very similar treatment to that of Hyacinths, except that decayed stable manure may be used instead of cow manure, and three bulbs should be placed in a pot instead of one. The single varieties are the best, and when well grown they are very showy and last a long time in beauty. Some few of the double sorts may be worth growing where there is a large collection, but I do not cultivate any of them. The most useful sorts both for exhibition and greenhouse are the following:—Chrysolora, Couleur de Cardinal, Fabiola, Le Matelas, Pottebakker (white), Proserpine, Keizerskroon, Rose Luisante, Van der Neer, Vermilion Brilliant, and Wouverman.

Polyanthus Narcissus may be placed next to the Tulip, and by many persons is preferred; they require very similar treatment, and may also be potted three bulbs in a 6-inch pot. Some of the varieties are better adapted than the others for early forcing, but all of them are beautiful, and the flowers are highly fragrant. The earliest sorts are the double Roman and the Dutch variety Paper White. They should, like the earliest Hyacinths, be potted early in September, when they may be had in flower from Christmas. Some of the best sorts for greenhouse culture are Bathurst, Bazleman Major, Grand Monarque, Grand Primo, Newton, Queen of the Netherlands, Soleil d'Or, and Staten General.—J. DOUGLAS.

### GREASY COAT APPLE.

I am inclined to think that the "book name" of the above Apple, which has been praised by "J. J., Lancashire," is the Transparent Codlin. This Apple may be frequently found growing in Lincolnshire, where it is highly esteemed for its good qualities. About a week after the fruit has been gathered it turns exceedingly greasy, or "clammy" as it is termed in the local vernacular, hence probably the name of "Greasy Coat." Many a cottager has paid his rent from a tree of "Transparent," and in that respect I have frequently had the best of evidence, having assisted in gathering and selling the fruit for "rent day."

The Lincolnshire Transparent forms a fine stately standard tree, and it is rare indeed that it does not produce a "paying crop" of fine fruit. The fruit is large and generally conical, although many specimens are somewhat flattened. The skin is a smooth light yellow, slightly flushed on the side next the sun. The stalk is short and slender, and is inserted in a deep and broad cavity, and this cavity is occasionally mottled with light dots. The flesh is exceedingly white, clear, and juicy, hence probably the name of "Transparent," which is certainly very appropriate. As a culinary Apple none is of better quality than this, and no Apple in its season is in greater demand by purchasers who are acquainted with it. It is ready for use in September, and the crop is generally gathered in October, when the fruit will keep almost until Christmas.

I have given these characteristics of the variety in order that "J. J., Lancashire," may judge whether it is the same as "Greasy Coat" which he has mentioned on page 257. If so, I can say with him that "I do not know any other autumn Apple to surpass it."—J., Lincolnshire.

PIKE'S PEARMAIN and Domino can be procured at Mr. Pearson's, Chilwell Nurseries, near Nottingham, but I am doubtful if what I called "Greasy Coat" is known under that name; I could never obtain any young trees of it, and my trees were

very large when I was a little boy, yet I cannot think such a very valuable Apple has been lost sight of. It is everything that can be desired as a cooking Apple, being large in size, rather flat, very short-stalked; colour greenish white, very rarely streaked with red, when fully ripe pale straw-coloured and remarkably greasy to the touch. The tree is of good habit as a standard, seldom requiring pruning; the blossoms are pure white. I hope someone will recognise it from my description.—J. J., Lancashire.

### VIOLET ODORATA PENDULA.

I FORWARD for your inspection a few blooms of *Odorata pendula*, or New York Violet. I have frequently been surprised in reading the remarks on Violets made from time to time in the Journal, that this charming variety is entirely overlooked. It has with me proved to be the greatest possible acquisition. Evidently a seedling from the Neapolitan, it nevertheless surpasses that grand variety in every particular. The plants from which the enclosed specimens were gathered are planted side by side with the Neapolitan, under precisely similar circumstances.

As yet the latter shows no sign of blooming for weeks to come, while *O. pendula* is laden with the most delicious flowers. The colour, too, is much more intense and pleasing; the Neapolitan being a pale greyish lilac, while *O. pendula* is a deep mauve, and when grown under glass usually shows a dark red eye.

The perfume is the same as that of its parent—the highest possible praise; for of all the Violet tribe, I could almost say of all flowers, not one is to be compared for sweetness with the Neapolitan Violet. One can only describe its scent as a mixture of the most delicate essences of Wallflower, Heliotrope, and Violet combined. Just so sweet as not to be cloying, just so strong as not to be overpowering.

This best of all Violets, too, appears to be much more hardy than the Neapolitan, blooming freely in the open air without the slightest protection, and standing both sun and wet well. The blooms sent were exposed all day yesterday to very heavy rain, and seem little the worse for it. It is a stronger grower than the Neapolitan, as you will observe by the foliage enclosed. The two large leaves are from *O. pendula*, and the smaller one (the largest I could find) from the Neapolitan, otherwise the plants are very similar in shape and colour, *O. pendula* being a rather lighter green.

Not one of the least of its recommendations is the extraordinary way in which it increases and the ease with which it may be propagated. A single plant last spring divided into between fifty and sixty pieces, all of which grew, and are now plants from 9 to 10 inches across laden with blooms. Besides these the summer runners have produced between one and two hundred smaller plants, some of which are showing bloom already. I can only add that as a frame Violet it is superb. Last winter it gave us a succession of blooms all through the season until the end of March, and was much admired by all who saw it.—R. W. BEACHEY, *Fluder, Kingskerswell, Devon*.

[We agree with Mr. Beachey that it is one of the varieties most worthy of cultivation. The size and doubleness of the flowers and their perfume are unsurpassed among Violets.—Eds.]

### MR. PEARSON'S GERANIUMS.

I QUITE agree with your correspondent "C. P. P." as to the merits of the new varieties of Mr. Pearson's Geraniums, most of which I have grown in borders this year; and the richness and grandeur of colour so far surpasses the old bedders that I can hardly imagine the latter being used where the others are known. The enormous trusses he mentions are a fine feature, but I wonder he does not name Mulberry, which I consider the most beautiful and most extraordinary, as to colour especially; and I would add Brutus, Mrs. Wm. Brown, and Charles Smith to the list of excellent and gorgeous novelties, all Mr. Pearson's.—J. H.

### THE ROSE ELECTION.

#### DECLARATION OF THE POLL.

OPINIONS doubtless will vary as to the quality of the Roses exhibited during the present season, a season in many respects most remarkable and much to be remembered by all interested in the vegetable kingdom. In one of my replies from Hereford occurs the following passage—"The unusual dry season has

had something to do with this, as until yesterday (August 20th) we have not had sufficient rain here to go to the roots of even Potatoes for nearly four months; last date, April 30th." When we reflect that during some portion of this time the heat was unprecedented in this country it is not surprising that vegetation should suffer, and yet, perhaps, to gather ideas from reports of exhibitions, the queen of flowers has never been exhibited in such brilliant form as during the past season. I hazard the opinion that the position of some Roses in this election has been materially influenced by the dryness of the weather, and that the light Roses have had a favourable time, and will accordingly be rather higher than heretofore; notably is this the case as regards Madame Lacharme, which has been exhibited at some shows in great beauty, even to forcing our good friend the Rev. J. B. Camm to acknowledge its merits. Yet methinks Madame, even when acclimatised, will never be an "all-weather" Rose; and it is noticeable that her position—not a bad one it must be acknowledged for one who has received no small share of abuse—is due rather to amateurs than nurserymen's votes; to those in fact disposed to offer some degree of protection to tender blooms. Personally I have never bloomed her ladyship well out of doors; under glass she is beautiful. One thing I have remarked in this very extraordinary season—that Maréchal Niel, which hitherto in my experience has made only an occasional effort at blooming in the autumn months, has this year come out in a perfectly new character. Only yesterday, September 7th, when standing at a window round a portion of which a Maréchal was trained, I counted over a dozen buds in various stages of growth. If the rest of the plant was at all similarly affected there must have been more than a hundred blossoms in prospect. My own trees, though not approaching this, have a far larger amount of bloom than I ever remember.

I had written thus far when the number of "our Journal" for September 7th came to hand, and in Rev. W. F. Radclyffe's remarks on the "ninety-and-nine" I find this:—"Louis Van Houtte (Lacharme). I have the other. This and Maréchal Niel are the two finest autumnals, but somewhat delicate." Now, if our friend Mr. Radclyffe means by this that Maréchal is our "finest autumnal" bloomer, he must be far more fortunate with this beautiful Rose than we are here, and it is another proof of the great difficulty of saying beforehand what Roses are best suited to any given locality and are most likely to succeed. So far as I have seen here, where nevertheless we all esteem the Maréchal highly, the blooms are in autumn "like angels' visits," and even, when they come, but a faint echo of the former splendours. Is not this, perhaps, another proof of the importance as regards the Rose, our national emblem, of a general election as to merits from growers all over the country? By this test we at least learn the general opinion of each Rose's merits, let their local habitation be favourable or the reverse.

I have adhered to the old plan in this election, but I have been asked by one contributor to put the question in a rather different form. He wishes twenty-four underlined as "best" out of forty-eight, or perhaps seventy-two, as being numbers suited to exhibition boxes. This idea is a useful suggestion, but the election was already commenced. Taking, then, the results as they appear from the returns of voting papers, I, in common with all interested, regret the absence of names we would gladly see still giving us the weight and influence of their voice. Some there are still sending me lists, heroes in the annual Rose courts; whilst there are new names, men of might in their own localities, who perhaps have never tempted fortune in distant competitions; but the whole result, though perhaps not absolutely free from error, will nevertheless give us, at the very lowest computation, out of the first fifty on the list at least forty-five that no Rose-grower should be without attempting to grow, and this is what we desire.

The table runs as before. The first column, a number denoting the position of the Rose at the poll; next comes the name of the Rose; then initials denoting its character; then its date of introduction; next the raiser (two columns more or less incomplete, but very useful, towards the completion of which I should be glad of help); then come the three columns of amateur votes—A denoting the number of votes the Rose has received in the first class, B the number of votes in the second class, C the total of amateur votes; the same letters with an asterisk denote the same votes of nurserymen. The last column shows the total number of votes received by any Rose. This column is the test of position. Roses receiving equal votes are bracketed together, but first-class votes of course

place a Rose in higher position than second class. With this explanation the table speaks for itself.

No.	Rose.	Character.	Age.	Raiser.	A	B	C	A* B* C*	Total.

Forty-seven electors prove to be so diverse in taste as to the necessary good qualities in a Rose, and what should entitle any

\* These Roses were, I believe, brought out by those whose names are attached to them, but I am not certain that the honour of raising them is also theirs.

candidate for the honour to rank among the premier fifty, that they name between them no less than 239 Roses, and even amongst the premier twenty 115 find a name if not a throne. In continuation of the table I may add that five Roses obtained each six votes, these being Duchess of Edinburgh, H.P. (one first-class vote); Le Havre (one); Boule de Neige (two); Lyonnais (two); Madame Margottin (one). Eight received five votes, Alba rosea having two and Eliza Boëlle one first-class vote. Thirteen were mentioned four times, amongst these the more recent introduction Marie Guillot had two first-class votes. Fifteen polled three votes, thirty-five two, and no less than seventy-eight found but one solitary champion to assert their charms. In round numbers this last class forms a third of the total, and, to make the matter still stronger, no less than eleven of these solitary votes are A1.

It may interest some of our readers to know how many of the Roses comprising the best fifty in this 1876 election have been named by the several electors in their voting papers. Of the fifty Roses that head the poll, Messrs. Ryland, Berrington, Atkinson, and Walters tie in naming the greatest number—viz., forty-one. Mr. M. Davis and Rev. J. B. Camm follow closely with forty; then thirty-nine are hit off by Messrs. Burrell and Beachey, and thirty-eight by Rev. C. P. Peach, Messrs. John Turtle, Cranston, Curtis and Corp. Messrs. Scott, Laxton, Christy, Cant, and Cragg single out thirty-seven. Messrs. Robson, Mayo, Fraser, and the returning officer are content with thirty-six; whilst Messrs. H. Davis, Mitchell, Davison, and W. Paul pin their faith on thirty-five. Thirty-four find favour with Messrs. Chater, Moseley, and Rev. A. Cheales. "A LADY AMATEUR, *South of Ireland*," Messrs. Mawley, Tapner, Jowitt, and Watkins (gardener to Mr. Wood of Henley Hall, Salop), Ewing, and H. Merryweather follow with thirty-three. Messrs. Turner, G. Prince, and Rumsay thirty-two each. At thirty-one Messrs. Jessop, Smallbones, Wootten, and Harrison meet. The Rev. H. Dombrian is solitary at thirty. Capt. Rochfort and Mr. Wheeler spot twenty-eight; whilst the list is completed by Mr. H. May naming exactly half the stipulated number. It is well there should be differences of opinion, and there is no royal road to our all thinking alike about Roses, yet the above summary proves that there are certain qualities of a good Rose—form, substance, and stuff that will hold their own even in spite of diversity of taste; and if the time ever arrive for these three qualities to meet in a white, or nearly white, Rose, coupled with a good constitution, the royal yellow and the dark Roses that now head the list may quake in their shoes—I mean their sepals, lest the pride of place be wrested from them. We have been hoping for years, when will it arrive?

In some instances the different estimation in which each Rose is held by amateurs and nurserymen is strangely brought out. Here in round numbers the voters are as three to two, yet in the votes for Sénateur Vaisse, John Hopper, Dupuy-Jamain, Souvenir d'un Ami, Abel Grand, Madame C. Joigneaux, and a few others, the amateur growers far outstrip this ratio; whilst—and this we should naturally expect—the newer varieties have a greater preponderance of nurserymen as their champions, as, for instance, Comtesse de Serenyi, which has rapidly risen into a good position; Marie Finger, of which Mr. B. R. Cant remarks that it is rather better than Eugénie Verdier, Hippolyte Jamain, and very markedly Princess Beatrice. I think there is probably another reason for this, that Roses that are shy in giving perfect blooms, which when perfect are exquisite and second perhaps to none, cannot be cultivated by amateurs having only a few plants of each variety, and after a few years are discarded. Twenty times the number of plants give the nurseryman many opportunities of seeing the Rose in perfection, and his estimate is formed accordingly. I have already noticed that Madame Lacharme comes out well, still I doubt whether it is a position that will be maintained; whilst what shall we say and how explain the position of Capt. Christy? In the 1875 election of newer Roses we see him making a gallant and very nearly successful battle for the premiership, passing those grand Roses François Michelin and Etienne Levé, and now it is as low as thirty-five, with a very small proportion of first-class votes. Is it to prove "an impostor," as somebody called it not long since in our pages? Marie Van Houtte, another Rose that the amateurs do not value in proportion to the trade, is lauded in no light measure by our friend Rev. J. B. Camm, for he says of her, "The best Rose in cultivation. It has every good quality (here at least), robust in growth, erect in habit, free-flowering, a wonderful constitution. I consider that M. Ducher has conferred on the Rose

world a benefit which we can never be sufficiently grateful for, and has made all lovers of the Tea Rose greatly in his debt for life." And truly Marie Van Houtte is a gem, but in my experience, like many other gems, not so large as you might desire.

The list will repay comparison with the 1874 election, September 24th, 1874. Some Roses are in exactly the same position now as then—for instance, Etienne Levé, François Michelin, Eugénie Verdier, Dr. Andry, and others. On the other hand, several Roses have made a remarkable advance. Marquise de Castellane and Horace Vernet from 37 to 19; Reynolds Hole from 60 to 30; Madame Lacharme from 58 to 34; whilst Comtesse de Serenyi, then unknown, is now in the fifty, No. 42. There are not wanting instances of failure to maintain position—Abel Grand from 33 to 47; Exposition de Brie, 33 to 60; though this latter may probably owe some of this to its similarity to Ferdinand de Lesseps, some electors declining to name both. Mr. Cant's list proves this. We miss, as I have already said, some of the old familiar names from the list of voters, but we have a larger number than we have ever had, no less than four coming from the sister isle. One of these latter arrived when the results were being tabulated, and is not included in the forty-seven voters, but will be given in full. This list is, however, included in the following table of the Irish votes, which I thought might be of interest to all, showing us the difference that soil, climate, and other circumstances make in the table.

## IRISH LISTS OF VOTES.

No.	ROSE.	A. B. C.	No.	ROSE.	A. B. C.
1	Louis Van Houtte.....	4 0 4	14	Maréchal Niel.....	3 0 3
to	La France.....	4 0 4	to	Gloire de Dijon.....	3 0 3
4	Duke of Edinburgh.....	4 0 4	16	Prince Camille de Rohan.....	3 0 3
	Charles Lefebvre.....	4 0 4	17	François Michelin.....	2 1 3
	Madame Rothschild.....	3 1 4		Madame Victor Verdier.....	1 2 3
5	Alfred Colomb.....	3 1 4	18	Dr. Andry.....	1 2 3
to	Marie Baumann.....	3 1 4		Marguerite de St. Amand.....	1 2 3
	Marquise de Castellane.....	3 1 4	to	Annie Wood.....	1 2 3
10	Sénateur Vaisse.....	3 1 4		Abel Grand.....	1 2 3
	John Hopper.....	3 1 4	25	Antoine Ducher.....	1 2 3
11	Comtesse d'Oxford.....	2 2 4		Jules Margottin.....	1 2 3

13	Fisher Holmes.....	0 4 4	26	Edouard Morren.....	0 3 3
			27	Mlle. Eugénie Verdier.....	0 3 3

Baron de Bonstetten, Boule de Neige, Abbé Brammerel, and Duc de Cazes follow with two first-class votes; Etienne Levé, Xavier Olibo, Camille Bernardin, Thérèse Levé, Clémence Joigneaux, Triomphe de Caen, and Baron Prevost have one of each class; and the next on the list are Devoniensis, Reynolds Hole, Anna Diesbach, Ferdinand de Lesseps, Paul Verdier, Maurice Bernardin, Souvenir de la Malmaison, Madame Vidot, General Jacqueminot, Charles Lawson, Duchesse de Morny, Duchesse de Caylus, M. Noman, and Comtesse de Jaucourt. Whilst these four electors choose no less than 104 Roses, fifty-one of which receive only a single vote, many of these last figuring very high up in the general poll—a proof not only of the difference of opinion, but also that varieties of soil and climate greatly affect the well-being of her floral majesty. Would the majority of Rose-growers have said beforehand that Fisher Holmes would have stood thirteenth in such a contest?

There is also another way of looking at the various Roses, and that is very interesting as compared with the general table. There are many Roses which we would all like to have in the fifty, yet which are considered by comparatively few first-class Roses—i.e., fitted to take their place amongst the best twenty. The following table shows the first-class votes given for each Rose and its position; taking these votes only, it will be noticed that amongst some the change in position is very great.

1.	Maréchal Niel	46		(Emilie Hausberg	15
Equal	Alfred Colomb	45	Equal	Devoniensis	15
	Charles Lefebvre	45		Marie Rady	15
4.	Marie Baumann	44	24.	Horace Vernet	18
Equal	La France	43		Marguerite de St. Amand	12
	Madame Rothschild	43	Equal	Ferdinand de Lesseps	12
7.	Louis Van Houtte	39		Souvenir d'un Ami	12
8.	Marquise de Castellane	35	28.	Reynolds Hole	11
9.	Etienne Levet	34	29.	Xavier Olibo	10
10.	François Michelin	31		Camille Bernardin	9
Equal	Comtesse d'Oxford	27	Equal	Capt. Christy	9
	Madame Victor Verdier	27		Souvenir d'Elise	9
13.	Duke of Edinburgh	25	Equal	Comtesse de Serenyi	8
14.	Mlle. Eugénie Verdier	21		Edward Morren	8
Equal	John Hopper	20	35.	Prince Camille de Rohan	7
	Dr. Andry	20	Equal	Marie Van Houtte	6
17.	Sénateur Vaisse	19		Niphetos	6
18.	Pierre Notting	19		Hippolyte Jamain	5
19.	Gloire de Dijon	17		Monsieur E. Y. Teas	5
20.	Catherine Mermet	16	Equal	Souvenir de la Malmaison	5
				Monsieur Noman	5
				Dupuy-Jamain	5

The above are sufficient to show how very much altered the first fifty are, tried by this test. The same standard varieties head the list, and the first change noticed of any importance is the elevation of that lovely Rose François Michelin. Dr. Andry makes a still greater move, as does Souvenir d'un Ami, a Rose which the nurserymen do not appear to value according to its deserts. I write this in all humility, but I cannot help adding that in my estimation few Roses are lovelier or more conducive to the beauty of a stand as it is seen here. Comtesse de Serenyi and Marie Van Houtte materially improve their position, and Mons. E. Y. Teas rushes from 75 to equal 38th. Such lifts in the newer Roses foreshadow a useful addition to our list. Capitaine Christy makes a slight rise.

On the other hand, let us glance at the retrogression of some. Devoniensis is considerably lowered, but this is slight compared to the fall of Xavier Olibo from 17 to 29th, or of Dupuy-Jamain from 29 to equal 38th, whilst Madame Lacharme falls quite outside the table, mustering only three first-class votes in her total of 29.

The general election furnishes fresh proof of the uncertainty of the new Roses and of what they may become. Anyone comparing these elections annually will see how some Roses that appeared to have a brilliant career before them are in a few short years names almost of the past; names which, heralded with a flourish of trumpets, have appeared, like a meteor on the Rose world, to disappear for ever. If we may judge from the votes, President Thiers, André Durand, Marquise de Mortemart, Souvenir de J. Gould Veitch, and Napoleon III. come in quite at the tail of the lengthy list, some only with a solitary vote, though it is equally certain that there are still a large number of good Roses, that everyone with a moderate collection would desire to possess, outside the pale of the fifty.

In concluding this portion of the election I desire to express my warmest thanks to all who have assisted me with voting papers and information, as also to those who with their lists have gratefully acknowledged the utility of these papers. Though personally unknown to them I value their kind expressions, and feel that there is something akin to friendly feeling generated, even when the subject discussed is only the merit of a flower. Some, perhaps, of the lists have been framed less carefully, at least I fancy. I have had to return more than usual from some informality; but with an Englishman's privilege we must blame the weather, for, perhaps, like Punch's cabby when the demanded fare was called in question, all might reply, "Well, anything you please, 'tis too hot to dispute about trifles."—JOSEPH HINTON, *Warminster*.

P.S.—Your correspondent, "ZUMMERZET YOKEL," will be pleased to find that some of his favourites, the Teas, stand fairly in this general election—not, however, Cloth of Gold; but then it is only here and there, very few and far between, that it finds a "local habitation" congenial to itself; but when it does it has no difficulty in making for itself "a name." I have in "Zummerzet" seen trees of it that have had their "local habitation" for a quarter of a century. Such a tree in bloom is a sight to be remembered, and, though savouring somewhat more of man's work than does the Gorse, might yet teach the beholder to pay a tribute of praise to the All-wise Creator for the sight, as Linnaeus is said to have done on his first sight of Gorse in full bloom; but these trees have a trunk the size of a good large arm, and have an air of antiquity about them. Doubtless he will be pleased to see Mr. Camm's opinion of Marie Van Houtte. We all have our tastes, and mine will lie between Souvenir d'un Ami and Catherine Mermet. I cannot say which would win, "t'other or which." When I look at "which" I am ready to vote instantly, and when I look at "t'other" I am equally ready to recall the vote. These two gems are kind to us, even in these hyperborean regions, where we have a continuous north-easter from the downs for eight or ten weeks in the spring, capable of taking off the nose of a brass monkey, and which does take the bloom off the blooms of scores of our Roses, even the hardier, if less beautiful, Hybrid Perpetuals. If "ZUMMERZET YOKEL" ends by giving us his list, what a Tea flavour there will be about it!—J. H.

### APPLES.

THE following succeed well at Lynwood, Hants, as we are informed by Mr. W. Gain, an experienced gardener:—*Dessert Apples*: May Queen, Joanneting, Devonshire Quarrenden, Early Margaret, Court-Pendu-Plat, Cox's Orange Pippin, Early Harvest, Oslin, Golden Pippin, Nonpareil, Northern Spy, Peach

Apple, Hubbard's Pearmain, Ribston Pippin, Boston Russet, Sam Young, and Winter Strawberry. *Kitchen Apples*: Chiswick Codlin, Hawthornden (English and American). The English is earlier than the other (the American), and preferable. Lord Nelson, Blenheim Orange, Emperor Alexander, Lord Suffield, Norfolk Beefing, Scotch Greening, Warner's King, Yorkshire Greening, and French Crab.

### TUBEROUS-ROOTED BEGONIAS.

THEY have this year proved a very attractive feature in the Mesembryanthemum and Heath house at Kew, and earlier in the season scarcely a day passed without inquiries being made as to where they could be obtained. Flowering commenced in early summer, and is still far from being over. To the majority of visitors they do not seem at all familiar. Although with common attention to the well-known principles of horticulture they can easily be grown, it may still be of service to detail a system of treatment found to give a good measure of success, especially as they are indispensable in every well-appointed garden.

In order that they may start with the greatest amount of health and vigour it is essential to have them properly cared for during the season of rest. The best position would be found in a house where only slight fire heat is used—sufficient to keep out frost, or a little more, and, if possible, they should stand on a bed of soil or ashes, where occasionally they can have a slight sprinkle of water if required. This is not unimportant, because if too dry they are reduced to a condition similar to the chalky state of wrongly-treated Caladiums. The sap is easily compelled to evaporate, and even if the roots are not killed they may become tough and flabby. The resting of plants is a rock on which there are many wrecks, and often because of excessive dryness.

It is, perhaps, best to let the tubers remain in the old soil until they show signs of growth, which will be about the end of March or April. They may then be shaken out, and should be put into pots just large enough to admit the fingers round the tuber easily. Good drainage is very necessary, because water must be given liberally, especially when growth is rapid. The compost should be rich, and so porous that the roots can easily penetrate it. Fibrous loam may constitute one half, the other half may be peat and leaf soil, and then some sand and dung should be added. It is not, however, necessary to be so very precise, since the mechanical condition is perhaps of most importance, though on no account must the soil be poor.

In a collection of several varieties it will be found that all do not start at the same time, so that more than once going over will be necessary. One shift after the first potting may often be found sufficient, though it is highly beneficial to give another shift just as the plants are coming well into flower. This will feed the flowers and produce them of good size; it will also enable the plant to continue growth, without which future flowers cannot be borne. Manure water is of great value when the pots begin to fill with roots. Careful watering is of importance, as they should never be quite dry at this period of their growth. Every evening is by far the best time to water, because they will absorb during the night, and be prepared for a day's sun on the morrow. It is very trying for these and other plants to stand dry during the night and commence the next day nearly exhausted. The female flowers should be picked off when past their best, unless, of course, seeds are required.

To propagate a stock it is of little use to sow seeds, because they do not come true, and only a small proportion are worth saving. Cuttings are easily struck, but they should be taken early so that good tubers may be formed. They may be treated much in the same way as Dahlias; but to put cuttings in now would amount to about the same thing. It must not be forgotten how very fine these Begonias are when planted on rock-work, and it may also be suggested that they would make beautiful beds.

The varieties found most effective in the Royal Gardens are Vesuvius, Dr. Masters, Sedeni, Chelsoni, Prince of Wales, Intermedia, Rosella, Roseflora, and Charles Van Eckhaute. Sedeni has had larger flowers than before seen by the firm who sent it out. This was one of the first hybrids, and from its distinct colour and qualities in general it is still one of the best. Dr. Masters is of a rich crimson, and similar in form to Boliviensis. Vesuvius is a flower of immense size, and is inclined towards orange. Chelsoni is desirable for its great profusion of bloom and freely branching habit. Prince of Wales

is of a rich crimson and allied to Dr. Masters. *Rosæflora* is of pyramidal habit, and the flowers are pink. Charles Van Eckhaute is a good white, but rather late.

### HOME ADORNMENTS.

To the various picturesque contrivances devised by Messrs. Dick Radclyffe & Co. is added that of a miniature floating island in association with their small room aquarium. The small figure of this submitted explains itself by showing how colour and perfume may be added to the usual aquatic plants by taking advantage of the adaptability of Hyacinths to this mode of decoration. That a pleasing effect can be produced in rooms and other places in the way suggested is very apparent. The plants employed are easy of management, and are certain to flourish without any special care or extraordinary

Fig. 44.

skill; and this, "the latest novelty" of the firm in question, is worthy of being submitted to those of the public who desire to see their rooms rendered attractive by artistic contrivances of this nature.

### INTERNATIONAL POTATO SHOW, ALEXANDRA PALACE.

SEPTEMBER 28TH AND 29TH.

SURELY never before in the history of the Potato, and that history has been a chequered one, has so much interest been attached to the tuber as in this our day and generation. Never before the past few years have such stimulants been offered for the introduction of new varieties, as well as encouragements been given for improvements in the culture of older sorts. This is almost entirely due to private enterprise, and if real good does not result no fault can attach to the promoters of such exhibitions as the one in question, for those immediately concerned have evidently worked well and for a good purpose.

There are those who can see no beauty in Potato shows, and are incredulous that any real benefit can arise from them; but on the other hand there are others, and not a few, who hold opinions diametrically opposite, who believe that exhibitions of Potatoes possess no ordinary attractions, and that the gathering together of the best samples of the best varieties extant cannot fail to be advantageous to the general community. The Potato in itself is not an object of beauty so much as an article of utility. But how often are these two qualities allied?

That the Potato possesses features which are attractive is as certain as that it possesses qualities which are agreeable to the palate. Possibly it is only those who have given special attention to the tuber who can fully appreciate its points of beauty, and who can discern at a glance whether that beauty is more than "skin deep." These are the experts—the enthusiasts; and it is well that there can be enthusiasts even in the matter of Potatoes, for enthusiasts in every branch of industry and science have ever been the pioneers of improvement.

Potato shows unquestionably afford a stimulus to the cultivation of new varieties, and kitchen gardens become thereby more interesting to their owners, the ground becomes better managed, and the natural requirements of the Potato are more studied by the cultivators. These are advantages produced by exhibitions. Other advantages are expected from these special shows. They should teach the public, through the judges, the standards of excellence desirable to be attained in endeavours to produce tubers in the greatest perfection. They should teach us not only that Potatoes to be perfect must be spotless, speckless, and scabless, and, if not eyeless, the growing parts must almost approach the "vanishing point," and that the form of the tubers must not be irregular and corrugated, but symmetrical, and without furrows or protuberances. These

considerata are generally acknowledged by the judges, but another important point, that of size, is not nearly so unanimously determined. It cannot be too urgently repeated that Potatoes to be acceptable must be of medium size. These are not only almost invariably the best in quality, but they are undoubtedly the most agreeable in appearance; yet how frequently do we find unwieldy size triumphant, and the big bearing away the palm of supremacy.

Besides desiring to see an authoritative veto placed against gigantic tubers, we desire especially to see the real qualities of varieties brought to the surface. This can only be done by cooking. The cooking of hundreds of dishes would entail considerable expense, but that in a measure might be met by competitors. We should like to see a great international handicap open to all the world and every kind, an entrance fee being paid on every dish submitted to the cooks. We should like to see the prizes substantial and numerous, and to know the nature of the soil, modes of management and manures used in producing the prize dishes. Unquestionable good would then result, valuable information would be forthcoming, and a competition of great interest and importance would certainly be produced. If the able and energetic managers of the Alexandra Potato Show could see their way to establishing a class of this nature they would more completely achieve the object which they have in view—improving the Potato and its modes of culture.

We will now look more immediately at the Show. There were seventeen classes, in the first of which prizes to the amount of upwards of £30 were offered. Two silver cups were provided, and other substantial prizes were offered by those who are more or less identified with Potato culture.

We will follow the arrangement of the schedule, beginning with the first and most comprehensive Class, A. This was for twenty-four varieties of Potatoes, distinct, nine tubers of each (open). All the prizes in this class were given by the Alexandra Palace Company, who contributed forty guineas to the general fund. The amounts of the prizes were £12 12s., £9 9s., £5 5s., £3 3s., and £2 2s. In this class fifteen collections were staged, and the Judges could not but have had considerable difficulty in distinguishing the relative merits of such admirable examples of culture, but eventually they awarded first honours to Mr. Porter of Old Meldrum. There could be no disputing the cleanliness, beauty, and finish of this fine Scottish collection, but a majority of the tubers were too large for table purposes. Porter's Excelsior were very large, but the tubers of Model were models as to size, as also were those of Rector of Woodstock, Victoria, and Albion Kidney. Other fine dishes were Select Blue, Bresee's Prolific, Climax, Snowflake, Wonderful (red), Napoleon, Ashtop Fluke, Crimson Walnut-leaf, Early Vermont, and Early King; while the Grampian, Blue Ashleaf, Napoleon, and Champion were rather coarse. The second prize went to Mr. Pink, Lee Court, Faversham, who also staged a splendid collection of medium-sized tubers; they were also smooth and well finished, but not so transparent as their larger rivals. Highly superior amongst the rounds were Model, Coldstream, Porter's Excelsior, Rector of Woodstock, and Red Emperor; Giant King was also good. The best kidneys were Birmingham Prizetaker, Berkshire Kidney, Bountiful, Bresee's Prolific, Hedley's Nonpareil, and Snowflake; other good dishes being Bryanston Kidney, Early Vermont, Prince of Wales, Magnum Bonum, and Late Rose. Many on-lookers considered this collection equal in merit to that which secured the premier prize, but it lost the honour by the unpardonable coarseness of Scamle's Glory, Ruby, and Blanchard. The third prize was awarded to Mr. Lye, Clyffe Hill, Devizes, but the tubers as a whole were wanting in clearness, although most of them were of the correct size. The best dish was Model, followed by Early Market, Climax, Bresee's Peerless, and Lye's Favourite. The best kidneys in this group were Snowflake and Bountiful. The fourth prize went to Mr. Peter McKinlay, Beckenham, who staged a collection containing some handsome dishes, especially of McKinlay's Seedling, a rather small but beautifully clean pebble-shaped tuber; also Model, Webb's Imperial, Royal Ashleaf, and International Kidney. The remaining dishes were more or less coarse, yet the collection was quite equal to the third-prize lot. The fifth prize went to Lott & Hart, Whitehall Nursery, Faversham, for a good collection.

In Class B, for eighteen varieties, distinct, nine tubers of each, open to gentlemen's gardeners and amateurs only, the first prize, a silver cup value £10 10s. was given by Messrs. Sutton & Sons, seedsmen, Reading. The remaining prizes were £10 10s., £6 6s., £4 4s., £2 2s., and £1 1s. For these prizes there were twenty-three competitors, first honours again going to Scotland in the person of Mr. G. Donaldson, Inverurie. This was a very superior collection, and merited the handsome cup which it won. The varieties comprised Hundredfold Fluke, Victoria, York Regent, Bresee's Peerless, Yorkshire Hero, The Countess, Rector of Woodstock, Long Blue, Early Handsworth, Bountiful, Bresee's Prolific, Scotch Blue, Snowflake, Early Rose, Early King, Early Goodrich, Webb's Imperial, and Main Crop, every variety being shown in admirable condition. The second prize was awarded to Mr. Finlay, Wroxton Abbey, Banbury;

the collection containing some splendid dishes, especially of Edgcott Seedling, which is similar to Snowflake, Porter's Excelsior, which closely resembles Early Handsworth, Rector of Woodstock, and Model; and amongst kidneys we noticed Sedilla and Lady Paget as attractive. Mr. Pink was placed third; Mr. Miles, Wycombe Abbey, fourth, his collection containing a splendid dish of Schoolmaster; and Mr. Miller, Northdown, Margate, fifth, each staging admirable collections.

In Class C, for twelve dishes of Potatoes, English varieties, distinct, nine tubers of each (open), all the prizes were given by the President, James Abbiss, Esq., J.P., and amounted to £13 13s. Eight collections were staged, Mr. Porter again winning with grand and finely polished examples of Napoleon, Blue Ashleaf, Champion, Excelsior, Ashtop Fluke, Round Blue, Early King, Bountiful, Rector of Woodstock, Crimson Walnut-leaf, Golden Eagle, and Grampian. Mr. Ironside, Aberdeen, being placed second; the most attractive dishes being Carter's Main Crop, Early Handsworth, Fenn's Bountiful, and Yorkshire Hero. Mr. Minchin, the Nurseries, Hook Norton, being third with rather large tubers, the best being Model. Mr. Pink had the fourth place with clean handsome dishes of tubers, which must have been considered a trifle too small, or the collection would have been placed a step higher. Turner's Union, around red variety, was very good in this collection, as also were Model and Waterloo Kidney.

In Class D, twelve dishes of American varieties, the prizes also amounted to £13 13s., the first prize of £6 6s. being given by Messrs. Daniels Brothers, seedsmen, Norwich. In this class there were eleven competitors, and the produce was decidedly more coarse than that in the preceding class. The first prize went to Mr. Pink for medium-sized tubers of King of the Earlies, Early Rose, Eureka, Ruby, Climax, Brownell's Beauty, Bresee's Prolific, Early Vermont, Bresee's Peerless, Onida, Early Goodrich, and Snowflake, all good. The second prize was awarded to Mr. Lumsden, Bloxholm Hall Gardens, who had grand dishes of Breadfruit, Snowflake, and Bresee's Peerless, the remaining sorts being somewhat coarse and large. The third prize went to Mr. Minchin for a good level collection, the best dishes being Snowflake, King of the Earlies, and Hundredfold Fluke; the fourth prize going to Messrs. Lott & Hart, Faversham, for a creditable collection.

Class E, nine varieties of Potatoes, distinct, nine tubers of each (open). All the prizes were given by Mr. John Coutts, James Street, Covent Garden, London. Nineteen collections were staged in this class, most of them being of high merit. Mr. Porter was again in the ascendant, his tubers being "got up" in the "highest style of art." Nothing could be more perfect than his dishes of Excelsior and Snowflake; the others, which were the same as those in Collection A, being also superior, but some of them too large. The second prize went to Mr. Finlay, Wroxton Abbey; Mr. Farquhar, Fyvie Castle Gardens, Aberdeen-shire, being placed third, Early Diminisk, a roundish flat Potato, being splendid; and Mr. Ironside fourth. A dish of Early Handsworth was very fine in this collection; indeed, all were good.

Class F, six dishes of Potatoes, distinct varieties, nine tubers of each, open to gentlemen's gardeners and amateurs only; first prize, a silver cup, value £5 5s. All the prizes in this class were given by Messrs. James Carter & Co., seedsmen, High Holborn, London, and brought forward not less than twenty-eight excellent collections. The silver cup was well won by Mr. Porter with such tubers as he alone can grow, dress, and show; the second prize also going to Scotland, Mr. Littlejohn, Corsendal House, Aberdeen, securing it with big Potatoes. Mr. Miles, Wycombe Abbey, was awarded the third prize. In this collection was a grand dish of Schoolmaster, a variety having the shape of Victoria with the scaly skin of York Regent. The fourth prize went to Mr. Finlay, Edgcott Seedling being in splendid condition.

Class G, six dishes, three round and three kidney, distinct varieties, nine tubers of each (open). The first prize of £4 4s. in this class was given by the Lawson Seed Company, Edinburgh and London. Fifteen exhibitors competed, Mr. Porter being first, Mr. Littlejohn second, Mr. Pink third, and Mr. W. Finlay fourth, who all staged admirable examples of popular show varieties.

Class H, four dishes, distinct varieties, nine tubers of each, open to gentlemen's gardeners and amateurs only. All the prizes in this class were given by Messrs. Hooper & Co., seedsmen, Covent Garden, London. Twenty-five collections were staged, Mr. Miller, Northdown, winning with Carter's Main Crop, Ashtop Fluke, Breadfruit, and Snowflake; Mr. Lumsden being placed second with Main Crop, again fine; also a capital dish of Excelsior. A collection without an owner's name was placed third, and Mr. Reynolds, Beech Cottage, Horsham, fourth. In these collections Main Crop and Snowflake were pre-eminent.

Class I, two dishes of English varieties, one round and one kidney, nine tubers of each (open), all the prizes being given by T. Kyffin Freeman, Esq., Pinner Wood, Middlesex. In this class eighteen competed. The prize-winners were, first Mr.

Finlay with splendid dishes of Lapstone and Rector of Woodstock; second Mr. Frisby, Blankney, with equally superior examples of Lapstone and about the best dish of Porter's Excelsior in the Show; third Mr. Littlejohn with Early Handsworth and Champion Kidney; and fourth Mr. Lumsden with Conqueror and Rector of Woodstock.

Class K, two dishes, American varieties, one round and one kidney, nine tubers of each (open). In this class there were twenty-four competitors; the first prize going to Mr. Carwill, High Street, Lewes, for grand dishes of Snowflake and Bresee's Prolific, Mr. Farquhar being second with Snowflake and Brownell's Beauty, Mr. Pink third with Vermont Beauty and Snowflake, and Mr. Lumsden fourth with Snowflake and Early Goodrich: a very imposing class.

Class L, dish of any white round Potato, nine tubers (open), all the prizes being given by Mr. John Harrison of the firm of Harrison & Sons, seedsmen, Leicester. This was also a very fine class, the exhibitors, thirty-two in number, staging admirable produce. The first prize was awarded to Mr. Porter for Excelsior; the second to Mr. Bennett, Enville, Stourbridge, for Schoolmaster; the third to Mr. Farquhar for round and handsome specimens of Snowflake; the fourth to Mr. Ross, Wreford Park, Newbury, for Criterion, a seedling resembling Schoolmaster.

Class M, dish of any coloured round Potato, nine tubers (open), all the prizes being given by Mr. Richard Dean, Ealing, London. Thirty-six exhibitors competed in this class, and much of the produce was coarse. Mr. Lumsden won the first prize with the most handsome dish of Main Crop that has perhaps ever been exhibited, Mr. Ironside being second with the same variety, Mr. Farquhar being third with Princess of Wales, which much resembles Main Crop, and Mr. Ross fourth also with Main Crop.

Class N, dish of any white kidney Potato, nine tubers (open). Thirty-one competitors entered the lists in this class, and many dishes of splendid quality were staged. Mr. Reynolds was placed first with Devonshire Seedling, a handsome white kidney; Mr. McIntosh, Corsendal House, Aberdeen, being second with Nonpareil, Mr. Lumsden third with Ashtop Fluke, and Mr. Finlay fourth with Edgcott Seedling. The prize dishes were very excellent.

Class O, dish of any coloured kidney Potato, nine tubers (open). Twenty-nine dishes were staged in this class, many of the tubers being coarse, and none really tempting in appearance. Mr. G. Bagerley, Sylverstone Lodge, Newark, was placed first with Early Vermont; Mr. Miller, Hampstead Gardens, Newbury, being second with a better dish of Late Rose; Mr. Porter third with unwieldy specimens of Blue Ashleaf; and Mr. Treacher, The Marsh, High Wycombe, fourth with Early Vermont.

Class P, dish of any variety of Ashleaf variety of Potato, nine tubers (open), all the prizes being given by Messrs. George Gibbs & Co., seedsmen, Down Street, Piccadilly. Twelve dishes were staged in this class, each of them being very good. The first prize went to Mr. Reynolds for handsome examples of La Belle d'Orleans, second to Mr. Farquhar for Sandringham Kidney, third to Mr. Lumsden for Veitch's Improved Ashleaf, and fourth to Mr. Miller for Royal Ashleaf. The prize dishes were very superior.

Class Q, dish of any white Regent Potato, nine tubers (open). Twelve dishes were also staged in this class, Mr. Finlay being first with Manchester Hero, Mr. Lumsden second with Rintoul's White Don; Mr. Armstrong, Goldington, Bedford, third with York Regents; and Mr. Baldwin, New Brompton, fourth with Early Don. The tubers in this class, excepting the prize-winners, were coarse.

Class R, dish of Victoria variety of Potato, nine tubers (open). We expected to find dishes of higher quality in this class. Out of seventeen competitors Mr. Finlay won first honours, followed by Mr. Abrahams, Firgrove Lodge Gardens, Weybridge; Mr. Kerr, Dargavie, and Mr. McKinlay, Beckenham.

Certificates of merit were awarded to Mr. Barker, Littlehampton, for a dish named "Superior." It is a red kidney variety, the tubers were of the correct size for cows, being too large for pigs; to Mr. Lye for Lye's Seedling, a handsome white roundish variety with russet eyes; to Mr. McKinlay for International Kidney, a large and beautiful white tuber, also for Alexandra Seedling, a fine white variety; to Mr. Lumsden for Conqueror, a seedling from Paterson's Victoria, but of kidney shape, with a rough cracking skin, by far the most promising seedling kidney in the Exhibition; to Mr. Fenn for Worthington G. Smith, an exceedingly handsome round white tuber of the Rector of Woodstock type; and to Mr. Ross for Garibaldi and Criterion.

There were also large miscellaneous exhibitions. Messrs. Carter & Co., High Holborn, exhibited a hundred varieties of Potatoes, including some splendid examples of Snowflake from the farm of H.R.E. the Prince of Wales, also a large collection of Gourds, ornamental Beet, and fruits of a Cucumber of great promise, the result of a cross between Tender and True and Telegraph. Messrs. Daniels Brothers, Norwich, exhibited upwards of eighty varieties of Potatoes, and Messrs. Harrison and

Son, Leicester, seventy varieties. Many highly superior dishes were included in these collection.

Mr. Amies exhibited Kales, Maize, &c., which had been grown on poor soil with the aid of his manures, and nothing more luxuriant could be imagined than these robust plants.

Mr. Turner had a certificate of merit for the fine new Dahlia Christopher Ridley, and similar awards were given to Mr. Rawlings, Romford, for Singularity, amber and white, and Earl of Beaconsfield. Mr. G. Smith, Edmonton, also exhibited Dahlias.

A new Melon, exhibited by Mr. Frisby, Blankney Gardens, Sleaford, attracted considerable attention. It is a seedling from Bloxholm Hall, the fruit being oval-shaped and handsomely netted on a greenish yellow rind. The flesh is of a deep green colour is tolerably firm, yet extremely juicy, and possesses a fine aroma. In the "judging" which this Melon underwent every particle of the fruit was speedily eaten—a rather unusual occurrence, especially during a season like the present, when Melons have been of indifferent quality. This fruit was named Blankney Hero, and was unanimously awarded a certificate of merit. It is not a little singular that two Melons of such high quality—Blankney Hero, green flesh, and Bloxholm Hall, scarlet flesh—should have originated in the same locality, the estates of Blankney and Bloxholm in mid-Lincolnshire, almost adjoining.

The Exhibition was arranged in the Concert Hall, the dishes being placed in six rows on five tables, each 100 feet in length, and the display was quite imposing. No doubt some inferior dishes were staged, the tubers being large and unshapely, but by far the majority were admirable examples of culture. The Show altogether was an excellent one, and highly creditable to Mr. McKinlay and his coadjutors. It was also well managed, the judging being quickly done and the awards promptly placed on the collections.

## ROYAL HORTICULTURAL SOCIETY.

OCTOBER 4TH.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. J. Ollerhead, gardener to Sir Henry Peek, Bart., Wimbledon House, sent a Queen Pine. He also sent a Melon Conqueror of Europe, and a dish of Trophy Tomato, to which a letter of thanks was awarded. Mr. Dean of Ealing sent a preserve made from Pumpkin, and strongly flavoured with lemon and ginger. It was considered a good preserve, but was too sweet. Mr. Francis Dancer of Little Sutton exhibited a dish of five specimens of Northern Spy Apple. Dishes of Madame Treve and Buerré Superfin Pears and Black Monnka Grape were received from the garden at Chiswick. Mr. Baker, gardener to Rev. G. W. B. Bell of Bampton, Farrington, sent roots of a red Beet, Excelsior, which was not considered an improvement on existing varieties. Mr. R. Westcott, gardener to the Duke of Cleveland, Raby Castle, sent a Capsicum called Princess of Wales, which was considered too much like Prince of Wales.

A very fine collection of Grapes was exhibited by Messrs. Lane and Son of Berkhamstead, which contributed very much to the interest of the meeting. Both in size and symmetry of the bunches and the size of the berries they exhibited evidence of very superior cultivation. There were three handsome bunches of each of the following:—Mrs. Pince's Black Muscat, Golden Queen, Black Hamburgh, Foster's Seedling, Black Prince, Buckland Sweetwater, Muscat of Alexandria, Gros Guillaume, Trebbiano, Gros Colman, Bowood Muscat, Muscat Hamburgh, Dr. Hogg, and Lady Downe's. The Muscats of Alexandria were especially worthy of notice from their size and their rich colouring. The Committee unanimously recommended the Council to award a Davis medal to Messrs. Lane for the exhibition.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. The Council-room presented quite a gay appearance at this meeting, and there was a good attendance of horticulturists. The tables around the room were well filled with an excellent group of Orchids from the collection of Messrs. Veitch & Sons. A fine display of Carnations in pots, Bouvardias, and Dahlias from Mr. Turner, Slough; table plants from Mr. Ollerhead, gardener to Sir Henry Peek, Wimbledon House, and other noticeable exhibits. The most striking plant amongst the Orchids was *Vanda cœrulea* with four spikes, one of which contained twenty flowers. *Vanda suavis* was also represented by a vigorous specimen. Amongst the Cattleyas in this collection we noticed *C. exoniensis* in two varieties, *C. Brabantia*, *C. Dominiana*, and *C. superba*. Amongst the Oncidiums were *O. Forbesii*, *O. crispum*, *O. macranthum*, and *O. tigrinum*, and there were small plants of *Odontoglossums*—*Rossii*, *vexillarium*, and *Roezii*; *Phalenopsis rosea*, *Lælia præstans*, and several *Cypripediums*. This was an exceedingly bright and effective group of plants, and for which a Davis medal was recommended by the Committee to be awarded.

The Carnations exhibited by Mr. Turner comprised about fifty plants in 5 and 6-inch pots, each plant being sturdy in growth, exceedingly healthy, and furnished with splendid flowers. Coronation, a rich crimson scarlet variety, was very striking;

Scarlet Defiance, Rose Perfection, Vestal (white), and Miss Jolliffe (flesh) are excellent perpetual bloomers; and amongst the flaked varieties Sir G. Wolseley, Gloire de Lyon, and Oscar were the best. These varieties, grown as here exhibited, are invaluable for winter decoration, and for affording cut flowers of the most enjoyable nature. A cultural commendation was awarded for the collection. The Bouvardias exhibited by Mr. Turner comprised admirably grown plants of *B. Vreelandii*, *B. Hogarth*, *B. umbellata alba*, and *B. longiflora flammea*. The plants were in 6-inch pots, each containing twenty to fifty heads of flowers. A vote of thanks was awarded. Mr. Turner's Dahlias were numerous and fine: first-class certificates were awarded to Christopher Ridley, a scarlet flower of superb form and finish; and to Burgundy, a fine flower, puce, shading to purple in the centre. Mr. Rawlings also exhibited Dahlias.

A first-class certificate was awarded to Mr. Wills, Melbourne Nursery, Anerley, for a new *Dracæna Gladstonei*, a magnificent and stately plant with broad arching foliage, bronze, heavily margined with crimson. Messrs. Veitch & Sons received a similar award for a handsome plant of the charming *Maranta Massangeana*. Messrs. E. G. Henderson & Son, Wellington Nursery, St. John's Wood, had a vote of thanks for a striking *Tillandsia* with crimson bracts and purple stamens. Votes of thanks were also awarded to Mr. Dean, Ealing, for dwarf French Marigolds; and to Mr. Ollerhead for lovely blooms of *Nymphaea dentata*. Mr. Ollerhead had a similar award for a group of well-grown table plants; he also exhibited a highly-coloured *Ananassa sativa variegata*, a large *Platycerium*, and a remarkable plant of *Selaginella phlegmaria*, resembling a miniature *Araucaria* laden with pendulous catkins.

Mr. Perkins had a vote of thanks for a bouquet of Begonias fringed with Ferns. W. Rayner, Esq., St. Andrew's, Uxbridge, exhibited *Amaryllis Rayneri*. Messrs. Rollisson & Sons, Cattleya Mylami, a cross between *C. crispata* and *C. granulosa*. Mr. Noble, Bagshot, *Gynurium argenteum pumilum*, which was certificated last year, and trusses of his new Rose Crimson Bedder, showing its extremely free and continuous-flowering character. Mr. G. F. Wilson exhibited a fine plant of a dark-spotted variety of *Tricyrtis hirta*; Messrs. E. G. Henderson & Son, Coleus Pine-Apple Beauty, similar to but brighter than Lady Burrell; Mr. Dean, Violet Victoria Regina; Mr. Chambers, Westlake Nursery, Isleworth, Begonia Magenta Queen, which had been grown in the open air, proving its suitability for window-box decoration; and a collection of cut trusses of Double Pelargoniums were exhibited from the Society's Gardens at Chiswick.

## AMERICAN ROSE AND SNOWFLAKE POTATOES.

HAVING grown the American Rose Potato on light sandy soil for several years, I find it to be a very heavy cropper and of excellent quality; but there is one fault I have to find with it, and that is it is rather pink in its flesh, and on that account it will not do for the parlour table, but it is undoubtedly a first-rate sort for market purposes. In my opinion it will be superseded by Snowflake, another American variety equally as productive; tubers large, beautifully shaped, and when cooked of the finest flavour. It boils mealy, and the flesh is as white as its name implies.—H. Mason, *Bisbrook Hall*.

## TROPÆOLUM SPECIOSUM.

I OBSERVE an answer to an inquiry respecting *Tropæolum speciosum*, which reminds me of what I have recently seen of that plant in the Highlands of Scotland and what hundreds of tourists must have been struck by. As we were leaving Loch Katrine and were driving through the Trossacks towards Callendar our attention was attracted to one of the modern villas which have invaded that silent region by a beautiful climber of a brilliant scarlet colour with which the walls were covered. We were not near enough to be able to find out what it was that produced the unusual effect. The botanical and horticultural knowledge of our party was exercised, and many were the suggestions to account for the cause of it. Our curiosity was kept on the stretch, and it was not till we reached Killin that we had an opportunity of examining what we were inclined to think was a new introduction. There, however, we found the plant covering the whole fronts of many of the cottages with as great luxuriance as the common Canary plant, and then we found it to be *Tropæolum speciosum*. On continuing our journey to Kenmore we discovered not only the toll-house just as you approach the bridge leading to the town, but an extensive trellis adjoining, one mass of scarlet flowers and beautiful blue-black fruit. The only term applicable to this remarkable sight is that it is gorgeous. How is it that the cultivation of this plant is confined to this part of the country, where it is perfectly hardy and grows without any care,

throwing up annually a perfect entanglement of rambling branches clothed with scarlet flowers? We afterwards found that the whole district is full of the plant, and that almost every cottage is more or less adorned with it in the summer. You recommend it to be kept in a greenhouse during the winter and planted-out to bloom in summer, but from what I have seen it is quite hardy, and it would be well worth while to try to establish it in other parts of the country.—A RAMBLER.

### TOMATOES AND THE POTATO DISEASE.

REFERRING to the statement of Mr. Moorman in his communication on the subject of Tomatoes in your impression of the 28th ult., that "in cold wet seasons they are liable to a disease similar to the disease in Potatoes," my experience appears to show that they take the true Potato disease from neighbouring Potatoes whenever there is wet weather, and this so certainly that it is useless to think of growing them in this county near Potatoes except under glass. I say in this county (South Wales), because it is possible that when grown against walls in the warmer southern counties of England a part of the crop at all events may be ripened in time to escape the infection.

In 1874 I grew Tomatoes surrounded on two sides by Potatoes at some little distance, the result being that the crop became badly affected soon after the disease made its appearance on the Potatoes. This year the same thing has occurred, while in two neighbouring gardens—one of which has no Potatoes in it, and in the other of which they were all dug in the middle of August—the Tomatoes have remained quite sound up to the present date (29th of Sept.), notwithstanding the almost continuous wet weather since the commencement of the month. It is certainly true that my Tomatoes were also healthy till a short time after the rains began (by which time I had gathered a few fruit), so that it appears that wet weather is necessary for the conveyance of the infection; but as, notwithstanding being subjected to the same weather that mine were, my neighbours' Tomatoes have escaped the disease, the neighbourhood of Potatoes appears to be a necessary cause of it.—A. BOYLE, *Amroth, S. Wales.*

### PRESENTATION TO MR. JOHN ROBSON.

VERY general was the regret which was felt by our readers when we announced the severe and sudden affliction which befell one whose name was so familiar to them and whose counsel was so reliable; and now equally great will be the satisfaction to learn that Mr. Robson has been able in person to receive a graceful mark of recognition from his friends and admirers. The termination of his labours at Linton Park was felt to be an appropriate time to recognise the merits of one who has done so much for gardening both by his work and pen. A committee was therefore formed and steps taken to carry out the project of a testimonial, and the labours of that committee closed in a pleasant manner on the evening of the 29th ult. in the village inn at Linton.

At a social meal there spread J. Philpott, Esq., as a principal promoter, presided, and after making a brief address vacated the chair in favour of J. Neve, Esq. (who was for many years Steward at Linton), and who was deputed to ask Mr. Robson's acceptance of the offerings of his friends. After duly honouring the toast of the Queen, Mr. Neve uncovered a handsome silver inkstand, and a purse containing £126 with a list of 160 subscribers, and presented them to Mr. Robson. In doing this Mr. Neve remarked that after having had close business connections with Mr. Robson for many years he desired to bear public testimony to his worth and ability. Not only as gardener, but as an accountant and assistant Mr. Robson had rendered him invaluable aid, while his character for integrity, industry, and urbanity had won him the approbation of all around him. Mr. Neve dwelt with emphasis on the generosity of Mr. Robson's disposition in ever seeking to impart knowledge and in being constantly ready to render assistance to all needing a helping hand, and his matured judgment had been of the greatest benefit, not only to the district, but also, through the press, to the general community.

When the applause had subsided, Mr. Robson, in the midst of an ovation almost overwhelming, in a modest speech and tremulous accents, accepted this one more mark of recognition which had been kindly rendered to him for "trying to do his duty." When he first became acquainted with the object of the Committee his first desire was to stop any further pro-

ceedings, but on further consideration he thought it would not be right to others for him to do so; therefore as an encouragement to others to labour for a reward, and also as his acceptance of the gifts of his friends might possibly enable him to better help some others who might be afflicted as he had been, he received with sincere thanks the kindness of those who had considered him worthy of their notice and regard.

On the inkstand was the inscription—"Presented to John Robson by his neighbours and friends, as a token of their regard and esteem.—Linton, October 1st, 1876."

The Secretary of the fund spoke of the many flattering letters he had received in regard to Mr. Robson; Mr. Bradley, Preston Hall, and Mr. Goddard, Hunton Court, alluded to his well-proved friendship to them and all gardeners to whom he could be of service; and the representative of the *Journal of Horticulture* acknowledged the valuable aid rendered by Mr. Robson to horticultural literature for a period extending over a quarter of a century.

Mr. Robson had already been the recipient of a gold watch and chain for his services in connection with the Maidstone Gardeners' Society, and he is held in the greatest esteem by all classes in the neighbourhood in which he has so long resided.

### POMOLOGY AMONG THE WOOLHOPIANS.

Who is there who has not heard of the Woolhope Naturalists' Field Club? which holds its annual celebration at Hereford, and where for many years, among other investigations into the natural history of the district, its members have performed such extraordinary feats in fungophagy as well as in fungology that the rest of the world have come to regard them as objects of a special Providence. Hereford is noted for other products than fungi, and having eaten or tried to eat every kind of fungus they could lay their hands upon they now turn their attention to pomology, and we hail as an augury of good results this disposition on the part of so accomplished and energetic a Society as the Woolhopes are.

For the first time in 1875 it was proposed that fruits should form objects of investigation on the occasion of the great annual meeting which is usually held at Hereford in September. The attempt to get together a collection of the fruits of the district being a new one, and as no great publicity was given to it, the number exhibited was not large. In the hands of such earnest people as the Woolhopes a small failure is only a stimulus to greater exertion; and this year, though the crop of fruit in the district is as partial as it is in almost all other parts of the country, the exhibition was for the year one which was full of interest, and was a token of greater things for the future.

The meeting was held in conjunction with that for the fungi in the large hall of the Free Library, and the collections crowded the surface of two wide tables extending the whole length of the room, and one cross table at the end. The number of plates was 637, of which 291 were occupied with Apples, and 346 with Pears. The exhibitors, of whom there were twenty-seven, were not attracted by the allurements of prizes, for this was an occasion for business, and not for "a show." The Woolhopes are not mercenaries, and whatever they undertake is in the interests of science without fee or reward, except what they derive from the consciousness of having contributed to the advance of knowledge.

Among the chief contributors were Sir Henry Stanhope of Holme Lacy, who sent forty dishes of Pears and twenty of Apples. The former were grown upon oblique cordons trained against a wall, which, judging from a photograph we have seen and reports we have heard, are the very perfection of good management. Nothing could afford better evidence of this than the remarkably fine specimens that were exhibited. This collection, and a very fine one of twenty-five varieties of Pears sent by Dr. McCullough of Abergavenny, consisted of the modern varieties grown for dessert, and they were both striking examples of what may be achieved when people are in earnest, both in the excellence of the fruit and the correctness of the nomenclature. Mr. Watkins of Marden sent forty-three dishes of Apples, Mr. John Bosley of Lyde thirty-five of Apples, Miss Lutwyche of Mynde forty-nine dishes of Apples and Pears. Mr. Griffiths of Tillington, the present occupier of Mr. T. A. Knight's old place, where he carried out many of his experiments, sent forty-two dishes of Apples and Pears, and among them we noticed more of Mr. Knight's varieties than in any of the other collections. This was naturally to have been expected, but it struck us as singular that in a county where Mr.

Knight lived, and in the interests of which he toiled throughout a long life, there should remain so few traces of his labours. With the exception of the Downton Pippin, and here and there a stray dish of one or two varieties, there was no evidence in this great collection of fruit of any great change or lasting impression he left behind him. The Rev. C. H. Bulmer of Credenhill sent twenty-five dishes, very correctly named; Mr. Hill of Eggleton sent twenty-four of Apples and Pears, Miss Guthrie of Hereford sent twenty-three of Apples and Pears, Rev. J. Davis of Moor Court sent twenty-five of Apples and Pears, all well grown, as were also the twenty-seven dishes of the Rev. A. Clive of Whitfield, and the thirty-three of Apples and Pears contributed by W. F. Herbert, Esq., of Credenhill; Miss Bulmer sent a good collection of twenty-four Apples and Pears, and Wegg-Prosser, Esq., of Belmont, contributed the large number of sixty-three dishes, forming a most interesting collection. Mr. Davis of Marden sent thirty dishes of cider Apples, and another collection of the same came from Mr. Davis of Burlington; Messrs. Cranston & Mayos sent twenty-four dishes of Apples and Pears, Capt. Doughty of Hereford fourteen, Mr. F. Boddendam of Hereford fourteen, Mr. Morris of Dewall fourteen, and Dr. Bull of Hereford fourteen. This collection of Dr. Bull's was remarkable for a dish of very handsome Gloria Mundi Apples, which formed a great attraction. The other contributors of smaller collections were Sir Herbert Croft, Mr. Curling, Mr. Cam, Dr. Moore, Mr. Hereford, and Rev. W. Thomas of Llanthomas.

We shall not on the present occasion go into particulars about the different varieties of fruit that were exhibited, with the exception of those grown for cider; and it will be interesting to many of our readers to know the names of those varieties which contribute to produce the noted vintages of Herefordshire. At some future time we will enter more in detail upon the individual merits and uses of the different varieties; meanwhile we append a list of those which were exhibited at this meeting.

Bromley.	Germain.	Red Norman.
Black Norman.	Green Norman.	Red Styre.
Crimson Queening.	Handsome Normandy.	Redstreak.
Cook's Kernel.	King Charles.	Styre.
Cowarne Red.	Kernels.	Sam's Crab.
Cowarne Queening.	Morning Pippin.	Skyrme's Kernel.
Com Apple.	New German.	Spreading Norman.
Cherry Norman.	Old Pearmain.	White Musk.
Foxwhelp.	Pig-nose Pippin.	Underleaf.
Forest Styre.	Philip Mandy.	Upright French.
Goose Apple.	Royal Wilding.	Yellow Styre.
	Rockley's.	

The frequency with which the names "Norman," "Normandy," and "French" occur in this list confirms the statement of contemporary writers, that it was through the exertions of Lord Scudamore in the reign of Charles I. introducing some of the best cider Apples from Normandy that the orchards of Hereford were so much improved. It was he also who introduced the Redstreak, hence called Scudamore's Crab, but we have no record whence it came or how it originated. For a long period after its introduction it was regarded as the most valuable of cider fruits, and Philips says—

"Let every tree in every garden own  
The Redstreak as supreme."

Now its place is usurped by the Foxwhelp, which yields a vintage not inferior to some of the renowned *crus* of France. This is notably the case at Credenhill near Hereford, where we can testify from personal experience that a sparkling cider of the most wholesome and generous description is made which is far superior to much of the sparkling wine that comes from abroad. An uneasy feeling exists among the orchardists of Herefordshire that the Foxwhelp is dying out. There is no ground whatever for this alarm. The old trees are certainly dying out, and will inevitably die out like every other organised body as the result of exhaustion and old age; but by careful selection of healthy scions and grafting them on vigorous-growing stocks, this and any other variety of fruit tree may be perpetuated in a state of perfect health. The contrary opinion advocated by Mr. T. A. Knight has been proved to be entirely fallacious, and no better instance of this could be given than that furnished by Mr. John Boxley of Lyde, who exhibited at this meeting fruit of the Foxwhelp yielded by trees which had been "five times past through the graft." The meaning of this is that scions had been first taken from the old tree and grafted on young stocks. From the trees thus produced more vigorous scions were again taken and grafted on young stocks, and this successive grafting having been performed five times, the result was a perfect regeneration of the

constitution of the tree, and a great improvement on the size and appearance of the fruit. This improvement of the fruit is considered an objection by the orchardist on account of the quality of the cider being inferior to that produced by the old trees, and being deficient of the peculiar smack and aroma which is the great characteristic of the matured Foxwhelp. This is an objection, however, which age will remove. It is well known that in all wine-producing fruits the quality of the liquor is much superior when made from fruit grown upon aged trees than from that which is yielded by young trees; and therefore as the trees become older so will the cider become relatively of finer quality. Fruit from young trees is always more succulent than from those that have attained to perfect maturity. This suggests the question, "When has a tree attained to perfect maturity?" The answer depends on the nature and individual constitution of the tree. Some are more robust and enduring than others, and some are more adapted than others to particular soils, and upon these depends the period when the several varieties attain perfect maturity. To arrive at this question most readily we have to observe what is the duration of the existence of the variety in a particular soil, and just as we estimate the perfect maturity of any organised being at middle life, so may we estimate the perfect maturity of an Apple or a Pear tree when it has attained what is known to be the half of the period of its average existence. We have no fear, therefore, that the Foxwhelp or any other variety that is worth preserving will ever die out if the proper means are taken to preserve it.

Dr. Hogg of the *Journal of Horticulture* was present by invitation, and in company with Rev. C. H. Bulmer and Dr. McCullough examined every dish, and corrected the nomenclature where this was necessary, supplying the names of such varieties as were wanting. Dr. Hogg has also undertaken to assist the Club in any attempts they may make in investigating the numerous fruits of the district.

Some may say, and some no doubt will say, "Of what use is such a meeting as that where no prizes are awarded?" We have already indicated that the Woolhope Club is a scientific body, consisting of gentlemen whose sole object is the advancement and cultivation of science, and we regard it as a great step gained that pomology has fallen under their protecting shadow. Every subject to which they have hitherto applied their attention has been benefited, and now that they have taken up the study and investigation of fruits we may hope for an elucidation of the pomology of one of the greatest of the orchard districts of England in a manner which has never even been attempted. The partial work of the late Mr. Thomas Andrew Knight, as we find it in his "*Pomona Herefordiensis*," gives a very inadequate idea of the extent and importance of the subject as it exists in Herefordshire alone. These orchards are teeming with varieties of great excellence of which the world knows nothing, and it is to be regretted that at the meeting held last week there were so many exhibited to which no names were attached. This omission we are informed was a reluctance on the part of the exhibitors to give the local names, from a supposition that they were all possessed of "book names," and that someone learned in the subject would be able to identify them. The fact is they had no "book names," and were never known out of their own districts, hence the importance at any subsequent meeting of having all such exhibited with the names by which they are known in the orchards where they are found. What we would recommend the Woolhope Club to do is to form a pomological committee of those of its members who make a special study of fruits. A committee not exceeding twelve in number would be found the most serviceable, and let them investigate the history of these nondescript varieties, compare them with the recognised kinds, and ascertain their relative merits and uses. Such a committee properly constituted and favoured with the benignant smile of the indefatigable Dr. Bull could do valuable work which would confer lasting benefit on the commercial enterprise of the county. Under the committee, too, a "*Pomona Herefordiensis*" worthy of the name could be produced which would become a permanent authority and work of reference on this important question.

### EUCALYPTUS GLOBULUS.

THE answer you have given to a correspondent in the *Journal* of last week respecting *Eucalyptus globulus* is no doubt applicable to England, but in Ireland it has been found perfectly hardy, and promises to be not a merely curious but a profitable

tree. At Muckross Abbey, Killarney, for instance, there are trees 30 to 40 feet high which have never been injured by frost; and at Sheldon Abbey, the seat of the Earl of Wicklow, it succeeds so well that his lordship contemplates planting it on an extended scale for useful purposes.—VISITOR.

### EARLY APPLES.

WILLINGLY, if not promptly, will I respond to the request of "WILTSHIRE RECTOR," and, as far as I am able, assist in determining which Apples are the most useful and profitable. I am ready to contribute my mite of experience for two reasons—namely, because the subject is one of general importance, and because the Rector is one from whose writings I have derived profit, and it would be selfish were I reluctant to offer a trifle in return. I regret having forestalled "WILTSHIRE RECTOR" in my sermonising on useful Apples, feeling that he is a better preacher than I am; but if I appropriated his sermon I left him a text on which he made some seasonable observations. Previously to entering on my subject I may mention, for the special gratification of our friend, that he has served me as bad as I served him. If I took as my text his text, and desecrated on the merits of Lord Suffield, Duchess of Oldenburgh, &c., the Rector has equally seized my idea in giving prominence to that valuable dessert Apple Irish Peach. This is the very Apple that was most prominent in my mind when I suggested that "A NORTHERN GARDENER" had omitted to mention some other good early dessert Apples. I can now only add my testimony to that of "WILTSHIRE RECTOR'S," that Irish Peach is one of the most delicious and valuable early dessert Apples in cultivation, and I join in the regret expressed that it is not more frequently seen on the tables of autumn exhibitions. Can it be the fact that an Apple so excellent is not in general cultivation, or is it considered too small for exhibition? for I observe that judges have a great fancy for "big" dessert Apples, and, as I think, on that point err.

I have cultivated the Irish Peach as an espalier on the Crab stock and as a pyramid on the Paradise stock, and I find it excellent under both modes of culture, but best from the Paradise stock—better especially in colour, and a little earlier in ripening. I find the tree to be a free grower, hardy, and productive, while as to the quality of its fruit I consider it superior to any other August Apple. Nearly all early dessert Apples are juicy and refreshing, but Irish Peach possesses these qualities and more, for it has an aroma which none of its contemporaries can approach. Its quality I may sum up as a mixture of Devonshire Quarrenden and Ribston Pippin, and I certainly advise all growers of early dessert Apples to try Irish Peach.

The next early Apple of superior merit which I felt was omitted from the short but good list on page 164 is the Oslin. This Apple in Dr. Hogg's "Fruit Manual" is honoured with six synonymes, which, by the way, is no small testimony of its worth. This Apple is a very favourite one in the midland counties, and I know also it is extensively and successfully cultivated "farther north." I have not tried it as a dwarf on the Paradise stock, but as a standard on the Crab stock it has given the most satisfactory results. The tree grows freely but not strongly, and is of compact habit, not attaining a gigantic head. It is a regular but not a heavy bearer, and the fruit is handsome and excellent, indeed is fully "as good as it looks," which is more than can be said of all Apples. The colour is yellow covered with brown dots. The fruit occasionally cracks, and this cracked fruit is generally most delicious. Boys are proverbially good judges of Apples, and the Oslin in an orchard of good sorts is their especial favourite. It is a favourite also with wasps, which is another mark in its favour. The flesh is crackling, juicy, and possesses a full rich flavour peculiar to itself. It ripens towards the end of August, and while it is excellent when eaten off the tree it continues good for three weeks after being gathered. This Apple I strongly recommend for summer use. I am indebted to the "Fruit Manual" for the following "bit of history" in reference to this good Apple:—

"This is a very old Scotch Apple, supposed to have originated at Arbroath; or to have been introduced from France by the monks of the abbey which formerly existed at that place. The latter opinion is, in all probability, the correct one, although the name, or any of the synonymes quoted above, are not now to be met with in any modern French lists. But in the "Jardinier François," which was published in

1651, I find an Apple mentioned under the name of Orgerau, which is so similar in pronunciation to Orgeline, I think it not unlikely it may be the same name with a change of orthography, especially as our ancestors were not over-particular in preserving unaltered the names of foreign introductions."

I add yet another Apple of the greatest value both for its earliness and excellence, and thus complete a trio not inferior to the trio named by "A NORTHERN GARDENER." The last I name is the earliest of the three. It is Early Harvest. In the manual referred to Early Harvest has no less than twelve synonymes. It is there recommended for espalier training on the Paradise stock, and the tree is referred to as a free but not a vigorous grower. I will now venture my testimony that on the Crab stock and grown as a standard it grows fully as vigorously as is desirable, producing large leathery foliage and very stout wood; in fact few kinds grow more freely than this, and few bear more satisfactorily. The fruit is of medium size and of a beautiful glossy yellow colour with a red tinge on the sun side. It is exceedingly juicy and refreshing, without possessing any particularly rich flavour, and is a most enjoyable Apple on a hot day. It ripens early in August. I hold this Apple in the highest estimation for its earliness and general good qualities, and I cannot conceive a collection being complete without it. I can name other good Apples ripening somewhat later than those named, but I consider them as being autumn rather than summer Apples. In this category I place Kerry Pippin. It is the really early Apples that are too often overlooked by those establishing collections, for my experience is precisely similar to that of "WILTSHIRE RECTOR'S," that at no time are Apples so thoroughly relished as during the hot days of summer.

I am now about to make a bold assertion, and challenge all England to name six early Apples better than these I have now named and the three recommended so worthily by "A NORTHERN GARDENER." I will, as near as my experience enables me to do, place them in the order of ripening: Joan-neting, early in July; Early Harvest, end of July; Irish Peach, early in August; Summer Golden Pippin, middle of August; Oslin, end of August; and Devonshire Quarrenden, end of August and early in September. The time of ripening varies of course in different districts and on varying soils, but the above I have found to be the order of succession of these six good summer dessert Apples.—A MIDLAND FRUIT-GROWER.

P.S.—Since writing the above the Journal of the 28th inst. has arrived. In reply to the inquiry in the correspondence column I can state that Domino, which was recommended by myself and "J. J., Lancashire," can be had both from Mr. Pearson, Chilwell, and Mr. Merryweather, Southwell. I have had trees true to name from both these nurseries.

### PEARS AND APPLES AT BONNYTOWN, ST. ANDREWS, N.B.

FOR a good many years I have been collecting varieties of Pears and Apples that would suit this soil and climate; and when it is stated that one variety has come here under its own proper name of Beurré Diel, and also done service as Colmar d'Été, Brown Beurré, and Doyenné Boussoch, it must be allowed that there are a few difficulties in the way of an amateur.

To gain information I have to-day sent off a small box with one variety of Pear and six of Apples to be named, as some grafts of so-called Clydesdale Apples appear to be of southern origin—e.g., Devil-may-care Apple is the Golden Winter Pearmain, and Bothwell Castle is Devonshire Quarrenden, and so it may be with others. No. 1 is called Star of Clydesdale, and is a very handsome and good early Apple. I hope it will not be passed before arrival. 2, Is it Hicks' Fancy? It is a great bearer as a standard. 3, Lady Wemyss, an early Apple, and a late specimen had to be taken; so it is not so well coloured as it should be, but it is a correct type as to shape. It is an immense bearer, and is sent because I heard a lady state that it was the best cooking Apple in her experience. 4 Came from London eight years ago as Nelson's Glory, but is not the Nelson's Glory of the "Fruit Manual," neither is Stirling Castle, at least as my tree of it goes. 5, Tower of Glamis. This variety is sent out here as Tower of Glamis, but it does not answer the "Manual," having five sides. 6, A free-bearing early Apple, which is very good when allowed to fall and eaten immediately afterwards. 7 Is a Pear which was named Susette de Bay, which it is not. The real Susette keeps till June, and is then not worth the trouble of keeping. Late

Pears do not come to perfection here on walls, so I have tried them under glass, where several succeed very well, this one amongst the rest; but it is a winter Pear, not a late one. It was of very fine quality until three years ago, when it suddenly became uneatable, as also did its next neighbour Zephirin Grégoire, another very fine winter Pear under glass. On examination it was found that the roots had penetrated the ferruginous subsoil; so of course this was removed, and it is to be hoped the fruits will be as good as ever.

Any information as to varieties that will ripen under glass with their full flavour, or at least with a finely diluted flavour, will be thankfully received by many of your readers as well as by—K. K.

## EARLY WRITERS ON ENGLISH GARDENING.

No. 19.

SIR JOSEPH BANKS.

GENUINE and ardent love of natural history and gardening in all its branches actuated Sir Joseph Banks in the great and

Fig. 45.—Sir Joseph Banks.

successful efforts he made for their improvement. He was born at Revesby Abbey, the seat of his father in Lincolnshire, in 1743. He was educated at Eton and Oxford, which University he left in 1761 on the death of his father. He thus inherited an ample fortune, yet the active pursuit of scientific discoveries was more to his taste than literary ease. In 1763 he made a voyage to Labrador and Newfoundland. In 1768 he went round the world with Cook, and in 1772 he made a voyage to Iceland and the western isles of Scotland. Natural history was the favourite of his scientific studies, and every department of it was enriched by his researches. In 1771 he was elected L.L.D. at Oxford. In 1778 he was created a Knight of the Bath and chosen to the Presidency of the Royal Society, and three years afterwards he was made a baronet. He at first gave much dissatisfaction to some of the members of the Royal Society, so as nearly to cause it to divide, but the dissatisfaction gradually passed away, and from that time until his death, May 9th, 1820, he was universally hailed as a munificent friend of science and literature. But he was also thoroughly acquainted with horticulture as a science and an art. He was the ruler as well as owner of his garden at Spring Grove. In the Transactions of the Horticultural Society between the years 1809 and 1820 he contributed essays on the Potato, Strawberry, Roman stoves, training fruit trees, American blight, and Fig culture.

Cuvier in an eulogium before the French Academy of Science

observed that ten times collections intended for the Jardin du Roi had been delivered up by the captors through the influence of Sir Joseph Banks; that men of science were aided freely by his library and purse, and that noble collection of books is still open to the public, for he bequeathed it to the British Museum.

Besides his numerous contributions to the transactions of various societies he published two small works, "An Account of the Causes of the Diseases of Corn called Blight, Mildew, and Rust," and "Circumstances Relative to Merino Sheep."

## ROSES FOR A SMALL COLLECTION.

I THINK that if a few of the small growers would express their opinion on the various merits of their favourites it would be a great boon to the class of which I make a part.

There is a class of Rose-growers whose selections vary, perhaps, from twenty to forty varieties, whose means would not allow them to purchase more than one or two of a few good varieties, but a Rose list usually contains such a diversity of names, colours, &c., that to pick a small lot from the owners' descriptions, which I admit are in general very good, a purchaser is at a loss where to begin and where to end. A few practical papers with the small growers' opinions of the various sorts which do best with him, and, stating the soil and position, would be a guide for intending purchasers of small means and requirements.

I will set the example, and state at the outset that the locality where I live is not one of the warmest in the midland counties, for Byron begins a well-known poem with

"Hills of Annesley, bleak and barren;"

but it is not only the climate, but the soil that is naturally cold, and we have often frost and snow until very late in the spring, which is very much against the forward culture of the Rose, yet in spite of all this we manage to grow some pretty good Roses; in fact not far, if any, behind our more favoured rivals, as returns show from our local exhibitions.

My position is an open and rather exposed one, with no shelter against the west and south-west winds. The soil is a heavyish loam, with clay about 1 foot 6 inches from the surface, so that I think that the soil makes up in part for the position.

I have about fifty varieties and about seventy in number. I will begin, not as they stand in the list, but as they stand in favour. One of the best, if not the best with me, has been this season Pierre Notting. I have grown it very fine. I have only one plant, and that is a half-standard. I cut for one show two blooms of this variety. Madame Victor Verdier is very good both on Briar and Manetti; Baroness de Rothschild, splendid; Marie Baumann, one of the best; Alfred Colomb, good, but I think a little wanting in colour; Louis Van Houtte, very good; Charles Lefebvre, rather thin this year; Etienne Levet, first-rate, never been short of a flower when wanted, blooms very freely; Countess of Oxford good, but requires shading, as the colour is soon gone; Comtesse de Chabillant, a very nice cupped Rose, rather small with me; Dr. Andry, a very good old Rose, blooms pretty well; John Hopper, pretty good, very hardy, but rather flat; Sénateur Vaisse, very good with me, but short in petal; Edward Morren, very good and full, but not one of the best to open; Annie Wood, grows very freely, and has had some good blooms; Marquise de Castellane, pretty good; Maurice Bernardin, a very good free-bloomer; Bessie Johnson, a very nice flower with a grand scent; Capitaine Christy, very fine flower, and I think will prove a good Rose; Reynolds Hole, very good in colour, but with me a rather shy bloomer; La France, very good rich colour, but it has failed to come out well this year; Dupuy-Jamain, pretty good; Madame Lacharme, somewhat better than last year, I think the season has suited it; Henri Pages, bloomed well, but the colour is rather dead; Souvenir de la Malmaison, a first-rate bloomer, but for exhibition wants showing in large bud, as it opens full much.

I think you now have a list of the best twenty-four for exhibition as they have grown with me, and I hope some other small growers will similarly contribute for the benefit of all.

—C. R., Notts.

MR. ALEX. MCKENZIE, Landscape Gardener and Garden Architect, of 1 and 2, Great Winchester Street Buildings, London, E.C., has had the honour to receive a magnificent diamond pin from His Majesty the King of the Belgians as a souvenir of his recent visit to Brussels, accompanied by a letter

from his resident Minister, M. Jules Devaux, thanking him for the advice he had given with reference to His Majesty's winter garden at Laeken.

### THE STANDARD CURRANTS & GOOSEBERRIES.

It is now about twelve years since this method of growing the Currants and Gooseberries has become general in Europe; since then it has rapidly assumed large dimensions, so that now they are quite an article of commerce with the nurseries there.

I first saw them at the Pomological Institute of Dr. Ed. Lucas at Reutlingen (where I spent two years), in the autumn of 1869. Being immediately taken up with the idea, I wrote Dr. Siedhof, my kind patron, about them. He wrote, "Send me a dozen," and since has largely increased the number—now having about fifty in all.

He has imported about one hundred more for special friends of his in different sections of Hudson Co., N.J.; so they have been thoroughly tested. Not a speck of mildew during seven years.

This method of grafting naturally does away with and supersedes the old and tedious method of trimming up the plants on their own roots to the standard form and then have it ruined by the borer, as *Ribes aureum* is exempt from the attacks of the borer.

The stocks are grown by stooling, removed and potted in fall and placed in a frame till about the holidays, when they are brought into a cool house—say from 45° to 50°.

In about three weeks they have started sufficiently for grafting to begin. The methods employed are the common whip-graft, without cutting the tongue, and the cleft graft for large stocks. Only perfectly well-hardened woody stocks should be selected, all others rejected. Previous to grafting they are kept shaded well. After grafting, however, they are given the full light and a little more heat. Bottom heat is not absolutely necessary, but, of course, in a measure is very beneficial. Frequent sprinkling after starting from the graft is also very beneficial.

By pinching the tips of the stocks we obtain branched heads, and so are enabled to set several grafts on one plant. Instead

of potting, some firms just envelope the roots in a ball of moss fastened with wire. These are very handy for shipping. They must at no time be kept too moist. Are saleable next fall as one-year-olds.

The fruit we exhibited at the Centennial were not show berries, as the English grow them, for the plants were literally loaded with fruit. We have measured berries  $5\frac{1}{2}$  by  $3\frac{3}{4}$  inches in circumference, weighing from  $1\frac{1}{4}$  to  $1\frac{1}{2}$  oz.

These statements are actual facts, and may be relied on. If these notes will be of any use to you we shall be glad to have you use them. —(*American Gardener's Monthly*.)

Fig. 45.—THE STANDARD GOOSEBERRY.

### ADIANTUM AMABILE.

AMONGST the species of the genus *Adiantum* there are already so many of sterling merit and beauty, that any new introduction must possess those qualifications in a high degree to be justly recommended for cultivation; nevertheless, some lovely aspirants have of late been added to the family circle, not the least worthy amongst which is the *Adiantum amabile*, than which no more appropriate specific name could have been given, except it were by the addition of "odoratum," a term peculiarly suitable on account of the agreeable perfume of the young fronds. This most distinct species was discovered by the late Mr. Pearce in Peru; it is a free-growing cool-stove Fern, attaining from 15 to 18 inches in height, the fronds averaging 14 inches in length by 10 ins. in width. The fronds are light green, thin, and membranaceous, and the pinnae small. These peculiarities, together with the gracefully curving lines assumed by the fronds and the pinnae, render it

one of the most lovely of the Maidenheads, and cannot fail to render it a favourite in all choice ferneries. It succeeds best in the intermediate house, and should be placed in a position where it can fully develop its fine drooping fronds. Direct sunshine, even as early as 7 A.M. during the summer months, is most injurious to the young fronds; the plants should therefore be placed in a position where it can receive sufficient light without being subject to the direct action of the sun. The pot should be placed on a cool bottom, such as ashes. The vapour arising therefrom is most conducive to the plant's well-doing.

Wooden lattice-work is about the very worst material on which to attempt Fern-growing; if such already exist, it can easily be covered with slate or zinc, with a layer of coarse sand or ashes upon it to hold moisture. The compost in which I have found this Fern to succeed best is a mixture of two parts fibrous peat, one part sandy loam, a little leaf soil not much decayed, with sufficient coarse silver sand and charcoal broken small to keep the whole porous and sweet.

If a large specimen is wanted in the shortest possible time it should never be allowed to become pot-bound, but be shifted on as the roots begin to travel round the pot. The finest fronds, both in *A. amabile* and *A. gracillimum*, are generally thrown-up when the roots have fairly filled the pot, but before the plant becomes absolutely pot-bound.

It is advisable with such quick-growing Ferns as the *Adiantums* always to have young stock ready to replace those that have spent their energies. During the summer months frequent dewings-over with the syringe will greatly benefit the growth, and should also be occasionally resorted to during the winter, especially if the plants are placed near to hot-water pipes. A temperature of 50° to 55° suits it admirably during the winter. It is easily propagated by means of the roots forming a dense mass of growth on the surface of the pot, which, if not removed, will very soon impair the growth of the mother plant. As a Fern for hanging baskets it will doubtless be in great request, as few Ferns look so imposing and so graceful.—A. W., *Lincoln*.

### GROWING HYACINTHS IN WATER.

HAVING grown a great quantity for a number of years I find the following points if carefully attended insure success: First, selecting those kinds that are best adapted for this mode of growth, a list of which I append. Secondly, the water, whether it be rain, river, or spring, must be clean and never allowed to become offensive. The bulb should be placed so that the water just touches the base; if higher it will be liable to rot the bulb. They should be put in a cool dark place until the roots have nearly reached the bottom of the glass, when they must be gradually brought to the light (avoiding the chimney-piece), in order that their leaves and flowers may be fully developed in a healthy manner. Keep them if possible in an equable temperature—extremes of heat and cold are injurious. As the water wastes the glasses must be replenished; keep them nearly full. By these little attentions spikes of flowers equal to those grown in pots or any other method may be obtained.

The following are a few Hyacinths best for glasses:—*Blue*: Baron Von Tuyl, Grand Lilas, Orondates, Argus, Charles Dickens, Prince of Saxe-Weimar, Bloksberg, Mary. *White*: Grand Vainqueur, Elfrida, Lady Havelock, La Tour d'Auvergne, Themistocles, Voltaire, Queen Victoria, Grandeur à Merveille, Anna Maria, Prince of Waterloo. *Red*: Robert Steiger, Duke of Wellington, Madame Hodson, Von Schiller, Lord Macaulay, Norma, Waterloo, Grootvorst, Lord Wellington (double rose).—W. B. L.

### THE ROCK GARDEN NEAR LEICESTER.

It is so seldom one has the pleasure of seeing a rock garden surrounded with wild and romantic scenery as this is, that I feel it would be an injustice to lovers of alpine if I did not give a passing notice of so lovely a spot. It is located on the outskirts of Charnwood Forest, on the east side, about seven miles from Leicester and five from Loughborough. I entered the grounds by the north entrance and ascended direct to the highest point. Looking from this elevated point eastward you see over the vale of Leicestershire, while just at the base of the hill are to be seen the disused slate quarries, now converted into fine sheets of water. Looking south you see the charming woods belonging to the Earl of Stamford and other owners, and in the distance Bradgate Park—in fact whichever way the eye turns some charming scenery presents itself. Having taken a good survey I began to descend in the direction of the rock garden and the newly-erected residence of Alfred Ellis, Esq. I had scarcely descended a few yards when I found myself in the midst of a dense plantation of Spruce, Pines, &c., through which I had to wend my way. This recalled to mind pleasant botanical rambles I had enjoyed in the neighbourhood of Ajaccio in Corsica, where the mountain sides, and frequently the summits, are densely clothed with *Pinus Laricio* and other species. The rock garden is

about half way down, and looks so comfortably and naturally placed that it would not suggest to the eye its being artificial if it were not surrounded by an iron fence and wire netting to protect the alpine from their enemies the rabbits.

The rockwork itself is not much elevated, but is in mounds, with large stones judiciously and picturesquely placed, with walks winding between. Nearly the whole can be viewed from the windows of the Hall.

The upper portion—that furthest from the walks, is planted with the coarser kinds of alpine, a few climbers, and dwarf shrubs; while the lower parts—those nearest the eye, are adorned with the dwarfer and rarer species of alpine plants, many of which have become uncommonly fine specimens. For instance, the dwarf *Phloxes* *P. verna*, *P. frondosa*, and *P. Nelsoni* have formed tufts three-quarters of a yard in diameter; the *Aubrietias*, *Sedums*, and *Acena novæ-zelandiæ*, have formed similar masses. *Polygonum vaccinifolium* was rambling away finely, yet very neat. *Geranium armenium*, with its large handsome rose and crimson flowers, was quite at home; so also was the fine autumn-flowering *Sedum spectabile*. There was a very fine plant of *S. Browni* (a plant I am afraid but little known). The *Campanulas* were quite gay; Mr. Ellis informed me that he had not succeeded with *C. Joysii*, which evidently requires to be kept both warm and dry during the winter months. *Nierembergia rivularis* was remarkably good, covered with its snow-white flowers. *Rubus arcticus*, the Arctic Bramble, was well represented; so also were the *Cistuses*, *Dianthus*, *Saxifragæ*. *Iris cristata*, *Onosma taurica*, and *Ramondia pyrenaica*, &c., were all excellent specimens.

Amongst the larger and stronger kinds used for the top I noticed *Yuccas*, *Statice*, *Lathyruses*, *Clematides*, *Berberises*, *Alyssums*, &c. Another plant which struck me as being extremely handsome was *Tropæolum polyphyllum*. I should say that its shoots were from 2 to 3 feet long, and abounding with large yellow flowers. This plant I consider is A1 as a rock plant or for covering banks. *Tropæolum speciosum* was also thriving well, but as yet in its infancy.

Mr. Ellis had adopted a very simple but effective method to supply with moisture those plants which require it constantly and regularly. It was by placing a common flower pot near the plants filled with water, the hole at the bottom of the pot stopped with damp clay, so as to allow the water slowly to escape; the pots are re-filled every morning. The only objection to this method is the unsightliness of the pots. The difference in the growth where the pots were placed was very apparent.

A little distance from the rock garden, about half way between that and the residence, were two circular beds cut out of the grass. In the centre of these beds were placed large rocks, so arranged as to give the impression that they were so placed naturally, while the remaining portion of the beds was planted with suitable flowers. The *Clematis* flowers would show well upon the stones if the plant rambled over them. These two beds were unique, they were in such perfect harmony with the surrounding scenery, and a sort of link between the real flower beds and the rock garden.—R. P.

### NOTES AND GLEANINGS.

A TREE of *CEDRUS DEODARA*, one of those forming the beautiful avenue of Deodars at Charleville, the seat of Lord Monck in County Wicklow, is now showing a profusion of young cones. We are not aware this has ever been observed before.

THE name commonly given to the *TRITOMA* is "Poker Plant" or "Red-hot Poker," neither of which can be considered either elegant or poetical. In Ireland it is called "Torch Flower," and we recommend this as a name more fitting for so beautiful a plant.

THE Commissioners of Her Majesty's Works and Public Buildings intend to distribute this autumn among the working classes and the poor inhabitants of London the surplus BEDDING-OUT PLANTS in Battersea, Hyde, the Regent's, and Victoria Parks; and in the Royal Gardens, Kew, and the pleasure gardens, Hampton Court. The clergy, school committees, &c., by applying to the superintendents of the various parks, will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

WE have received the prospectus of an INTERNATIONAL HORTICULTURAL EXHIBITION which it is proposed will be held in Carlisle in 1877. It says—"The central position of the

border city and its remarkable railway facilities are so well known that the proposal will not only be encouraged by the leading local horticulturists, but will also be largely supported by the principal London and other metropolitan exhibitors, as well as by those on the Continent." A provisional committee has been formed, of which Mr. W. Baxter Smith is the Chairman; and a meeting of influential supporters will shortly be held, when fuller details will be entered into. We cordially wish the enterprise the greatest success. Such an exhibition we hope will be well supported on the borders; and if the great populations of the mining and manufacturing districts on the east and the spinners of Lancaster and Preston can be attracted in sufficient numbers, we see no reason why the undertaking should not be a financial success, weather permitting.

— *GREVILLEA ROBUSTA* is used in the mixed "subtropical" bed in front of the No. 2 Museum at the Royal Gardens, Kew. It is one of the most elegant subjects for this style of gardening, and we do not remember having seen it so used elsewhere. It might be classed with *Acacia lophantha*, as affording beautiful fern-like foliage, but from its more dwarf habit is adapted for other combinations. If seeds are sown now it would be easy to raise plants a foot high for planting-out next season. They should, however, always be sown when received, as the proportion of plants obtainable soon diminishes, though fresh imported seed may be expected to produce a good crop. Plants in 48-sized pots are extremely useful for a variety of purposes; for window and table decoration they are valuable from the durability of their foliage.

— "J. S., Lanark," writes—"With reference to the notice taken in your Journal of the 7th September (page 211), of the Cockscombs grown by Mr. Hawes, Henerton, I think it right to state that there are to be seen growing at Ridgepark, near Lanark, the seat of Charles Lindsay, Esq., a lot of Cockscombs of splendid quality, measuring, one 42½ inches by 16 inches across the comb, another 41 by 16, another 39 by 15, and the rest on an average 35 by 12, all grown in 10-inch pots, and the plants only 10 inches above the pots. The grower, Mr. Henry Sime, gardener, Ridgepark, like Mr. Hawes, has been well known for years in connection with the cultivation of Cockscombs, and this year without the slightest difficulty he carried off first honours at Glasgow and Edinburgh exhibitions, besides, of course, our local show."

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

EXCEPT gathering and arranging fruit there has not been much done in this department. It is quite necessary to gather the fruit when it is dry, and also to handle it carefully. Fruit that has begun to decay is removed at once. The importance of doing this cannot be too much impressed upon those who have, like us, little to spare and are anxious to make the most of what they have. Nearly all the fruit has been gathered from the walls, and when this is done the trees may be looked over, and any pruning that is required should be done. We do the most of this in the summer season, and as a general rule but little of it is required now. It is always necessary to look over the trees, and to cut off any spurs that project too far. It has always seemed a rough method to take a stumpy birch broom, as some do, and switch the decaying leaves off; but it is some advantage to remove them, as the sun and air can then act more freely upon the trees. When the leaves are switched off in this way the work ought to be done with a new broom, and the shoots should be gently stroked upwards, never the reverse way of the buds. When there are only a few leaves they may be gently removed by hand, and the trees should be gone over about twice a-week. It is more particularly Peach and Nectarine trees that require this attention. The American blight can readily be discerned on the trees now, and should be destroyed by dipping a small brush in paraffin, or we have found boiled oil effectually destroy it. It ought to be well worked into the crevices of the bark, where the insects find shelter.

A correspondent inquired last week about the treatment of Raspberries; they had not made sufficient growth to produce fruit. Now, the Raspberry requires generous treatment, but it often has the very reverse of this; the plants are stuck into any sort of ground without having any preparation made or manure applied, and odd corners that will not grow any other crops well are thought to be good enough for them. In hot dry districts about the best position for Raspberries is a border behind a north wall, and if the soil is light a few cartloads of heavy clay soil will be of great advantage. The border ought to be trenched

and manured in the same way as has already been advised for Strawberries. The way we have found Raspberries give the best results from a given piece of ground is to plant the canes in rows 3½ feet apart, and 18 inches between the plants; grow about three canes to each plant, and tie them to stout wires strained tightly along the rows about 3 feet from the ground; the canes should be cut at about 3½ feet from the ground. Of course, the method of training has nothing at all to do with the bushes not bearing. If the young wood is strong and well ripened, and the varieties good, they must bear fruit. The Raspberry is also fond of a good supply of water at the roots. Any time in fine weather after this Currant and Gooseberry bushes may be planted out. They will get established before the winter season sets in, and will start into more vigorous growth next season.

### VINERIES.

The early houses are being prepared for forcing in the way that was recommended a few weeks ago. If we could, in addition to other washings and cleanings, have the inside woodwork painted, say every second year, it would be an excellent deterrent to many insect pests. Besides red spider, ordinary house spiders lodge in the crevices of the walls and woodwork, and as soon as the berries are formed the smaller spiders get into the centre of the bunches, and by-and-by they work their webs round the outer sides of the berries, very much injuring the bloom. In late houses where the Grapes are quite ripe much care is necessary to prevent decay in the fruit. Decaying leaves must be removed at frequent intervals, as it is when the leaves are decaying in the house that there is most danger from mould on the berries, causing decay. If the fruit is not quite ripe no time must be lost in keeping up the proper degree of heat, say from 60° to 65° in the Muscat house, and 5° less in the Black Hamburgh house. Lady Downe's and Alicante require as much heat as Muscats to finish them off well.

### PINE HOUSES.

Where fruit is now ripening attention must be given to ventilating the house as much as possible, but the temperature must be kept sufficiently high to bring up the flavour in the fruit—65° at night, rising to 75° or 80° by day with sun heat. We have been cutting Charlotte Rothschild and Smooth-leaved Cayenne, and a variety introduced from the mountainous districts of Columbia named Mordilona. It is said to ripen in a lower temperature than other Pines at present in cultivation in our English gardens, but we have tried it with the other sorts only. The leaves are much like those of the Smooth-leaved Cayenne, and the fruit has the appearance of that variety, but it is not so symmetrically formed. The fruit is very juicy, and will be a good winter variety. It is not necessary to say that the atmosphere should not be very moist, although it will be necessary to damp the paths and walls in bright weather twice daily, and once in dull weather. Succession houses for the present must be kept moderately cool at night. The Pines that we intend to start early in January are now kept dry at the roots with a bottom heat not exceeding 85°, and the temperature of the house about 55°.

### PLANT STOVE AND ORCHID HOUSES.

This is a very dull time for flowers in this department, but we are never altogether without them. The *Stephanotis floribunda* has flowered profusely, and its pure white delicately-scented waxy-looking flowers are always welcome. Very useful, too, is the *Urceolina aurea*, a Peruvian bulbous plant introduced by the Messrs. Veitch of Chelsea some years ago. Its yellow-greenish-tipped pendulous flowers are distinct and pretty. We grow it with *Amaryllis*, and the same treatment suits it. The *Amaryllises* are now at rest in a cool house. The soil has been allowed to become quite dry, and no water will be given to the roots until it is time to start them into growth. This should be done at different times, so as to obtain a succession of flowers. Ours are started with a little bottom heat and a temperature of 50° to begin with, increasing it to 55°, which is high enough in the winter season; but if it is necessary to raise the temperature to 60°, or even 65° to suit other plants, this will not be hurtful to the *Amaryllises* if bottom heat is supplied at the same time. When the bulbs are started in a high temperature without bottom heat, this forces the flower stalk up prematurely, the result being that the flowers are produced without the leaves, which is not desirable.

Some of the Orchids are now in flower, and most welcome they are at this season. *Lælia autumnalis* is in full beauty; the flowers are very handsome, but subject to disfavour on account of their powerful odour, which is disagreeable to most persons. Certain *Masdevallias*, such as *M. Veitchii* and *M. Harryana*, have thrown up autumn flowers. We never had the last-named species do so in the autumn before this year. The autumn-flowering variety of *Dendrobium formosum giganteum* is also showing fine flowers, and they last in good order for nearly two months at this season. The different varieties and species of winter-flowering *Calanthes* are now throwing-up their flower spikes. These plants are easily grown, and well worth all the attention required to keep them in good condition. The most useful sized pots are those about 5 or 6 inches in diameter. About three

bulbs are potted in each in good turfy loam with a little stable manure added to it. Small bulbs will produce one spike, and those of a larger size two spikes of flowers. *C. Veitchii* is the most noble of all this section. The bulbs in strong plants are sometimes over a foot long, and throw up spikes from 4 to 6 feet in length. In striking contrast to it are the different forms of the *C. vestita* section, with pure white flowers; and others with white flowers marked with red or yellow. They will thrive well in any plant stove with a temperature of from 60° to 65°. The leaves are infested with brown scale sometimes, but this is easily removed with a sponge and soapy water. As there is much danger from damp to be feared at this season, great care is necessary in watering Orchids; only give water when necessary, and avoid as much as possible spilling it on the leaves or pseudobulbs. All the shadings have been removed from plant houses, and also from the Orchids, except those from cool parts, such as *Odontoglossum crispum*, *O. triumphans*, *O. odoratum*, &c. We still shade these from bright sun, and do not stint them for water at the roots. The surface of the compost in the pots is usually covered with live sphagnum, and when this is kept in a healthy free-growing state it is not likely that the Orchids suffer from want of water. Where insect pests abound, and as work is not pressing, now is a good time to adopt means to extirpate them; still, the most effectual way to destroy mealy bug is to use a soft sponge and soapy water, and patiently wash each leaf and branch by hand. It is also well to destroy green fly by fumigating; there is not so much danger of injuring the young growths at this season as there is in summer.

#### FLOWER GARDEN.

Cold nights and muggy damp weather warn us that it is time to see that all bedding plants intended to be potted should be seen to forthwith. The Tricolor Pelargoniums have been already done. If they are not fairly established before the cold weather sets in many of the plants damp off through the winter. It is best to pot the plants in comparatively small pots, and remove all the oldest leaves before doing so. It is also a mistake to cut back any of the growths, as decay sets in at the cut part and spreads downwards. As soon as the beds are cleared of their summer occupants no time should be lost in planting the early spring-flowering Tulips, Hyacinths, &c. The herbaceous border requires to be looked over—all decaying stems removed, and the more free-growing subjects must be cut back where they are intruding on their more delicate and weakly neighbours.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

William Paul & Son, Waltham Cross, Herts.—*Catalogue of Roses.*

Ewing & Co., Eaton, near Norwich.—*Catalogue of Roses.*

Godwin & Son, Nursery, Ashbourne.—*Catalogue of Roses, Fruit Trees, &c.*

George Yates, Underbank and Royal Oak Mills, Stockport.—*Illustrated Catalogue of Flower Roots.*

Little & Ballantyne, Carlisle.—*Catalogue of Roses, Rhododendrons, Herbaceous Plants, &c.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

HULL. October 10th, 11th, and 12th. Mr. J. Chappell, 96, Prospect Street, Sec.

JERSEY (ST. HELIER'S) (Fruit), October 11th. (Chrysanthemums), November 8th. Col. H. Howell, Hon. Sec.

NORTHAMPTON (Chrysanthemums), November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit), November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

MARGATE. August 29th, 1877. Mr. C. D. Smith, Hon. Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

HOUSEMAID'S BARROW.—Under the above name a correspondent procured what he terms "a valuable garden liquid-manure distributor with one wheel, the same as a common barrow." He obtained it through an advertisement in our columns; he desires to know if he can obtain a similar article.

ROSES IN POTS (*E. L. W.*).—If you refer to our number published on August 31st of this year (No. 895), you will there find full directions for their culture.

SOIL FOR RADISHES (*Inquirer*).—Your soil is too rich, as the Radishes only produce tops. The red and the white Turnip-rooted varieties are to be sown now. There is no mode of driving away rats except by ferreting them.

FRUIT CULTURE (*An Old Soldier*).—Our "Fruit Culture for the Many," price 4d., free by post 6d.

TITLE TO GRAPES (*J. H. S.*).—You would probably be considered only a lodger, and that the Grapes on the wall are the landlord's. You had better agree to divide the crop.

NAME OF TREE (*James Long*).—It is impossible to be certain from such a specimen, but we think it is the common Alder, *Alnus glutinosa*.

NAME OF LILY (*C. R.*).—It is *Lilium tigrinum*, the Tiger-spotted Chinese Lily. It was introduced during 1894 by Mr. W. Ker, and cultivated in Kew Gardens. Kempter says that the Japanese eat the bulbs.

POTATO HAULM MANTURE (*J. H.*).—You are quite wrong in thinking it objectionable because it is poisonous. It decays in the soil, and its elements only after that decomposition are absorbed by the roots of the crop. Drift sand is as serviceable as silver sand if all earthy particles are washed-out from it.

SCHOOLMASTER POTATO.—"H. G. B." wishes to know where this can be purchased.

FUCHSIA AND FUNGUS (*T. E.*).—The Fuchsia is a morphological sport, and the bit of fungus no one could identify.

WALNUT-LEAVED KIDNEY POTATO (*I. W. A., Reader*).—It is not the same variety as the Ash-leaved. The leaves are of a different shape, size, and colour, the stems more dwarf, and the tubers smaller. Miniature Hyacinths we believe are only small specimens of the common Hyacinth.

GREASY COAT APPLE.—"N. H. P." suggests that this may be the "Greasy Pippin" mentioned by Downing in his "Fruits and Fruit Trees of America."

CHARCOAL FOR VINE BORDERS (*W. Kinneer*).—The best way is to mix it with the compost when the borders are prepared. Two bushels to a cartload of soil is a good proportion. If your borders are made and you wish to apply it, you can do so by spreading a bushel to each 9 square yards of surface and digging it in. It is best in lumps from the size of a walnut to a man's fist.

FUCHSIA LEAVES EATEN (*An Old Subscriber*).—The leaves have been eaten by some weevil or caterpillar. Probably you would find them at work were the plants closely examined, particularly if the former—i.e., weevils, be the cause, by examination of the plants at night. Were the plants syringed with a solution of soft soap it would make the shoots and leaves distasteful to the insects.

CLIMBERS FOR CONSERVATORY (*B.*).—You have all the fragrant climbers. Either you will have to have duplicates, in which case there is none finer or sweeter than *Mandevilla suaveolens*, but you appear to be without such fine subjects as *Lapageria rosea*, *L. alba*, *Tacsonia Van-Volxemi*, *Habrothamnus fasciculatus*, *H. aurantiacus*, and *Luculia gratissima*. The two latter are sweet.

CUTTING-DOWN OLD VINES (*R. G. M.*).—In cutting-down near the ground the object is to secure young rods in place of the old, as that tends in a higher degree to facilitate the flow of the sap than through old worn-out wood. We have tried both—i.e., cutting to within a few inches of the ground and to the bottom of the rafters, and had good results in both cases, but the former is much the better of the two. By all means retain the young shoot, and cut the old cane or rod away just above the young shoot.

GERANIUMS LEGGY (*Amateur*).—The soil probably is too rich and loose. We should firm the soil so as to induce slow growth, or plunge the plants in the pots so as to cover the rim about an inch deep. The cause usually of Tricolor Geraniums withering or browning at the edge is mostly from excessive moisture over the leaves, especially after a period of dryness.

SAWDUST MIXED WITH HORSE DROPPINGS FOR MUSHROOMS (*T. H.*).—We have used the droppings from a loose box bedded with sawdust for forming Mushroom beds, and never had a more abundant crop nor longer continuance of fleshy Mushrooms. We only wish we had some at command. No fungus of a deleterious kind accompanied the Mushrooms.

LEAVING EDGINGS OF GOLDEN FEATHER PYRETHRUM (*An Amateur*).—We presume the plants are very dwarf and compact, in which case and being plants from seeds recently they will answer admirably, being very effective in spring. A little fresh soil placed around the plants up to the stem will do good.

AMERICAN BLACKBERRIES (*Leeds*).—We know of no nurserymen in England who sell these varieties.

LIME FOR SLUGS (*Novice*).—Quicklime is better than gaslime for destroying slugs. Dust the surface with the lime until it is white, and repeat the application if needed. It is applied most effectually during the evening when the slugs are moving about.

SELECT DAHLIAS (*S. B. G.*).—*Acme of Perfection*, Lord Derby, Alexandra, Scarlet Gem, Thomas White, Sir G. Smythe, John Standish, Paisley Paul, Criterion, Mrs. Stancomb, Lord Palmerston, Charles Backhouse, Ada Tuffin, Countess of Pembroke, Mrs. Dorling, James Hunter, Her Majesty, Lady Jane Ellis, Lady Derby, Andrew Dodds, Julia Davis, Miss Henshaw, Lothair, and James Wilder. Those are show varieties, which you must not exhibit with fancies, a dozen of which are—Mrs. Saunders, Rose Flake, Grand Duchess, Flossy Williams, Marquis of Lorne, Flora Wyatt, Harlequin, Gem, Mrs. Goodwin, Rev. J. B. Camm, Chang, and Lord Dalkeith. The others in your list we do not know.

TEA-SCENTED ROSES (*E. S.*).—*Cloth of Gold*, a Noisette, which you prefer to *Maréchal Niel*, would succeed admirably against the wall. All those you name would succeed well, but all Tea-scented Roses require protection in winter except in warm situations.

WORKING SEEDLING BRIARS (*Idem*).—You may pot the plants and keep them plunged in coal ashes about an inch over the rims of the pots, taking care to keep them well supplied with water. The only fear is too weak growth, and rooting beyond the pots. They may be turned out of the pots after the buds have taken.

RAISING PINUS AUSTRIACA FROM SEED (*Idem*).—Sow the seeds in March in light sandy soil in an open situation, covering them about three-quarters of an inch deep. The seedlings should be transplanted in the autumn in rows a foot apart, and 3 inches distant in the rows.

INSECTS LIKE WASPS BORROWING IN A DEAD TREE (*W. H. Cooke*).—The insect you have observed is not one of the social wasps (*Vespa vulgaris*), but a solitary species, *Crabro leucostomus*, which has selected flies to deposit in its cells for the support of its young when hatched.—W.

INSECTS ON PRIMULA LEAF (*L. M.*).—The very minute insect and the leaf sent are in so shrivelled a condition that it is impossible to determine the name of the former. Its relics look like the very small caterpillar of a moth.—W.

**NAMES OF FRUITS (A. H. Pearson).**—1, Alexandrina Bivort. The Apple not known. (K. K.).—1, Nonesuch; 2, Early Nonpareil; 4, Nelson's Glory; 5, Not Tower of Giammi; 7, Fondante d'Antoine. (R. P. Hawksley).—Gravestone. (R. C. C.).—4, 5, and 10, Court-Pendu-Plat; 7, Caral's Seedling; 9, Coe's Golden Drop. (J. E. Ransom).—1, Trumpington; 2, Borsdorfer. (D. Deal).—Not known. (R. C. C.).—1, Emperor Alexander; 2, Manks Codlin; 3, Too much decayed before it could be examined. (E. M. P.).—Tom Patt is the name of a popular Apple in Somersetshire, but we do not think that this is that variety. It is like the Tom Patt of Herefordshire. (Connaught Subscriber).—1, Belgian Purple; 2, Was rotten before it could be examined. (Knutsford).—1, English Codlin; 2, Mère de Mège; 3, Rotten. (F. M.).—The red-striped Apple, not known, the other is Birmingham Stone Pippin. (X. Y. Z.).—Not known. (W. O. E.).—Not known. (E.).—1, Winter Peach; 2, Lewis' Incomparable; 3, Summer Stibbert; 4, Evidently a local variety; 5, Margil. Pear—2, Swan's Egg. (Eob).—The Grapes were rotten before they could be examined. (L. D. W.).—Blue Imperatrice. (P. C.).—Not known. (Connaught Subscriber).—1, Barbe Nellis; 2, Decayed before it could be examined. (Stuart & Mein).—Not known. (H. W. W.).—1, Morning Pippin; 2, Pearson's Plate. (S. W.).—1, Hoary Morning; 2, Sweeny Nonpareil; 3, Beauty of Kent; 4, Claygate Pearmain. (Thomas Laxton).—We cannot identify the Apple sent. (G. B. R.).—The Apple is the Yellow Siberian Crab. The Pear not known. (Ewing & Co.).—The Plum is Black Bullace; Claygate Pearmain is Scarlet Nonpareil. We do not know the other. (North Clays).—A good early Apple. (J. A. P.).—2, Beurre d'Amande; 6, Beurre Diel; 8, Doyenné Gris; 9, Christie's Pippin; 10, Lord Suffield; 12, Yorkshire Greening.

**NAMES OF PLANTS (W. Musgrave).**—It is *Physalis alkekengi*, Winter Cherry. It is hardy, may be obtained of any seedsmen or florist, and treated like any other border plant. (Fens).—1, *Datura* (*Brugmansia*)  *sanguinea*; 2, *Pellaea rotundifolia*; 3, *Achimenes* sp.; 4, We cannot name florists' varieties of *Begonia*. (J. H.).—A young form of the Bracken (*Pteris aquilina*). (H. S.).—1, *Campotesorus rhizophyllus*; 2, *Pellaea atropurpurea*. (H. R.).—A *Solidago*, probably *S. lanceolata*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### OUR DUTY TO OUR FOUR-FOOTED AND FEATHERED NEIGHBOURS.—No. 1.

"We defy augury; there is a special providence  
In the fall of a sparrow."—*Hamlet*.

It is my purpose in this and future papers to inquire, without prejudice, and keeping mere sentiment at a distance, as well as the thought of sport where sport is only selfish and useless cruelty—to inquire, I say, what is our duty to our four-footed and feathered neighbours.

We speak of "wheels being within wheels," noting the reasons that lie inside of reasons, sometimes pretended reasons first and given; real reasons within and concealed. But if there are wheels within wheels, what a number of worlds are within this world! There is the world of being, thought, act, and inclination, which you and I, grown-up reader, are living in, each in our own world. Go up into a nursery; each little one there has equally his own world in which he or she is living, in which a toy, or a sweetmeat, or that awful being "nurse," have force and power. Descend and go into the kitchen; each servant is living in his or her world, each human being in a world, much of which no one else is cognisant, for

"Not even the tenderest heart, and next our own,  
Knows half the reasons why we smile or sigh."

But around us there are other living beings—beasts and birds, each with its own feelings, following its own pursuits, its own plans, absorbed in providing for its own life, having its own loves, and hates, and fears. What cares the rabbit for man's feelings or sufferings? It is absorbed in its own world, and full of fear oft for its own life; or why does it stop and lower, and then move upward and around its beautiful trumpet-like ears, formed specially to catch the slightest sound? Caesar may dream that the world is made for him, but I think that pert cock sparrow twittering on the end of a house roof may just as likely think that this world was made for him. "What's Hecuba to him, or he to Hecuba?" but his little brown mate sitting on her eggs close by is much to him—part, great part, of his little world.

Next, man is the greatest power in the world, and since he made for himself by his skill firearms he is all-powerful over the world of beast and bird. They know this, and they dread his face, save in those islands where man was a stranger. Thus the dodo of the Mauritius allowed himself to be caught by man, and was soon exterminated by man, thus paying the penalty of his confidence. Poor trusting dodo! many a woman has trusted man just the same, and to her sorrow and to her destruction not seldom.

Man the master, the autocrat, of the world, and all other living beings in the world fearing him! This fear is beautifully dwelt on by Mr. Blackmore in a grand book of his, "Lorna Doone," a work in which the author has done as much for Exmoor as Charles Kingsley did for Bideford and its neighbourhood by his "Westward Ho!" The hero of the book, looking back upon an event in his childhood, thus writes:—"A long way down that limpid water, chilly and bright as an iceberg, went my little self that day on man's choice errand—destruction. All the young fish seemed to know that I was one who had taken

out God's certificate, and meant to have the value of it; every one of them was aware that we desolate more than replenish the earth. For a cow might come and look into the water and put her yellow lips down; a kingfisher, like a blue arrow, might shoot through the dark alleys over the channel, or sit on a dipping withy bough with his beak sunk into his breast feathers; even an otter might float down stream, likening himself to a log of wood, with his flat head flush with the water-top, and his oily eyes peering quietly; and yet no panic would seize other life as it does when a sample of man comes"—man the master and the destroyer.

Such is man's power. No emperor ever was so absolute over men's limbs and lives as is every man over the world of beast and bird around him, and no vassals or slaves ever fled from his pursuer as does every beast and bird. What, then, is our duty to our four-footed and feathered neighbours? The Maker equally of the poor brute and of ourselves has spoken on this subject. He said, "Thou shalt not muzzle the ox that treadeth out the corn," meaning that the poor labouring brute should be able to eat of the straw around him. Such the Great Father's kindness to the four-footed. But the bird has not been forgotten:—"If a bird's nest chance to be before thee in the way in any tree, or on the ground, whether there be young ones or eggs, and the dam sitting upon the young or upon the eggs, thou shalt not take the dam with the young, but thou shalt in anywise let the dam go and take the young to thee; that it may be well with thee, and that thou mayest prolong thy days." There is to be no extermination of birds, as they do good, not harm, if preserved in suitable numbers. Then there is the couplet of J. Montgomery founded on a well-known verse:—

"MAN: The gun is levelled, quit that wall.

"SPARROW: Without the will of Heaven I may not fall."

He who says "He feeds the ravens," and "whose are the cattle on a thousand hills," and He equally "preserveth man and beast." It is not, then, for us to be murderers, to take life for no cause or a bad cause. We have our duty to fulfil to the world of beast and bird. There is the sentimental view as expressed in the lines—

"No flocks that range the valley free,  
To slaughter I condemn;  
Taught by that Power who pities me,  
I learn to pity them;  
But from the mountain's grassy side  
A guiltless feast I bring—  
A scrip with herb and fruits supplied,  
And water from the spring."

This is mere sentiment. A feast from fat oxen is as guiltless as of watercresses. The animals were given us for food; and not only us, but all the carnivora have teeth and stomachs on purpose for the mastication and digestion of animal food. We are to kill, but we ought to kill humanely.

In England during the past thousand years many animals and birds have been exterminated, and many more destroyed in too great numbers.

In regard to birds in England a thousand years since, specially in the fens of Cambridgeshire and Lincolnshire, I subjoin an eloquent allusion to their numbers from as good a naturalist as novelist—Charles Kingsley, who in his "Hereward the Wake," who lived in the time of William the Conqueror, thus writes in a description of a journey by water from Bourn to Crowland Abbey:—"And they rowed away for Crowland, by many a mere and many an eddy; through narrow reaches of clear brown glassy water; between the dark green alders; between the pale green reeds; where the coot clanked, and the bittern boomed, and the sedge bird, not content with its own sweet song, mocked the notes of all the birds around; and then out into the broad lagoons, where hung motionless, high overhead, hawk beyond hawk, buzzard beyond buzzard, kite beyond kite, as far as eye could see. Into the air, as they rowed on, whirled up great skeins of wild fowl innumerable, with a cry as of all the bells of Crowland, or all the bounds of the Bruneswald; while clear above all their noise sounded the wild whistle of the curlews and the trumpet note of the great white swan. Out of the reeds, like an arrow, shot the peregrine, singled one luckless mallard from the flock, caught him, struck him stone dead with one blow of his terrible heel, and swept with his prey into the reeds again."

Now, of all the birds mentioned in this beautiful piece of word painting how few remain, at least in the fens. No bittern now booms there, no buzzard and kite sail in the air, no curlews, no great white swans; and as to the peregrine, he has retired to the Highlands of Scotland, and from thence higher up to Iceland, from whence he flies for a meal back to Scotland.—WILTSHIRE RECTOR.

### MICHAELMAS TIDE.

THE brown and golden leaves are beginning to strew the runs which are shaded by limes and chestnuts. Feathers abound everywhere, and flit through the wire netting of the yards and come to a standstill in flower beds and garden paths. The

grass in the runs begins to look tufty and coarse. In fact everything begins to look untidy, and we are told that autumn has come.

With Michaelmas day we began a new list of poultry shows and commenced putting things in train for the great season of important exhibitions. Up to then we had only had chicken shows of moderate excellence; but in October and the following winter months well-got-up schedules arrive by nearly every post, and the full whirl of important exhibitions is upon us. Before this comes to pass, when we are now in Michaelmas tide, which is the turning point in this new quarter, let us take a brief retrospect of what we have seen at the summer shows.

First of all, taking all the chicken shows and chicken classes collectively, we think the average quality and number of birds has been very fair, and perhaps 1876 has so far been marked by a more even proportion of good specimens in all the varieties than is usually the case. We should think Cochins and Light Brahmas have on the whole made the best display, while Dark Brahmas have made the weakest. Considering the wholesale way in which they have been in the habit of being bred and exhibited, we almost are inclined to believe this fashionable breed is beginning to lose admirers and that its glory is departing. We fancy the older-established Cochins are once more regaining their position which the Dark Brahmas temporarily seemed to wrest from them. Most certainly there has not been that display of Dark Brahma chickens which we have seen in other years; and Bath, which in former Septembers has been so very conspicuous for its chickens of this breed, this year mustered but three cockerels, and those in no way up to the standard of former times. We fancy winning became too difficult, and was in the hands of so very few, that many fanciers turned their attention to other breeds which held out greater chances of prizes. Cochins, we believe, are as popular as ever they have been, but even with them trade is not very brisk; in fact, we heard one of our oldest breeders say but last week that he had never known such utter stagnation in the poultry world as regards sales. There have been some good Dorking chickens out, and the judges seem to fancy the Silver-Greys very much; for at Hereford, Weymouth, Aylesbury, and other shows we find this variety taking the cups before their coloured brethren. Hamburgh chickens in the north have been plentiful and good; the Blacks more especially have been wonderfully good. The French we have not seen in the numbers we have been in the habit of seeing at the chicken shows of past years, but the quality of those which we have seen has been quite up to a good average. In the Polands the year so far has been remarkable for the great excellency of the White-crested Blacks. We consider this one of the most lovely of all our breeds, and hope the chickens have not only appeared at the summer shows but will also appear equally strong at the winter exhibitions. In Leghorns the Club has been making a stir and furnishing prize money right and left. We hardly think so far the entries have been as numerous as they should have been, but we can quite imagine it is no easy work all at once to put a breed upon its own footing. There have been some good Spanish about, and a nice Malay or two. Silkies have been perhaps rather more numerous than usual, and we hope the extra classes they are now having will lead to still further cultivation of this most useful little breed. Among Bantams in the south the Game have been but poor, while Laced and Blacks have come to the front better. In Waterfowl, Ronen Ducks have been so far extremely good. Of Indians we have seen also some splendid pens for colour. Black Cochins have not come to the fore very much, and it seems difficult to get size with other good points. Thus much for the birds generally during these summer shows; now we look forward to large classes and good quality, and expect Oxford to produce many wonderfully good specimens hitherto unshown.

It has been remarkable this year how late the large yards have been, but we look forward to seeing now a good display from them. Another thing we have especially noticed this season is how in the early chickens one brood would consist of all pullets and another of all cockerels. This of course is a great drawback to early exhibition. Among the shows themselves we are sorry to find one or two have died. Of them we particularly regret Long Sutton. Middleton near Manchester has left its old date, and now comes under a new quarter of the exhibition year. We lament most especially the falling through of the Alexandra Palace meeting; and though certainly we have a very welcome new arrival in Ipswich, still we could not afford to lose the sister Palace's exhibition.

Of the exhibitors we note with much pleasure that many of our oldest fanciers have been winning well in the summer shows. Mr. Sedgwick we congratulate heartily on his wonderful Cochins victories. Mr. J. K. Fowler has been well in the lists, so has Mr. Beldon; and Messrs. Burnell and Cresswell not only have done brightly, but will, we think, from the rumours of the quality of their stock, even surpass other years' successes. Of new exhibitors we have not seen many, but we hope they will come. We cannot have too many; the more the merrier. And no one can have a better time of entering the poultry arena

than the present, for birds were never so moderate in price as they now seem to be. In case any amateurs are looking out for good openings where they may have a chance of soon winning prizes we would recommend them to turn their attention to Black Cochins and Cuckoo Dorkings among the large breeds, and to clean-legged White Bantams or to Sebrights among the smaller varieties.

In judges we have had no fresh blood, but we rejoice very greatly to hear one of our oldest fanciers of the utmost integrity has consented to judge the Cirencester poultry show. We do not know if we are at liberty to give his name, but when the poultry exhibitors hear it we think they will welcome him as cordially as we do.

Thus much for the summer times. The new quarter has begun, and in that quarter we hope to find new shows, new judges, new exhibitors, and new birds.—W.

## IPSWICH POULTRY SHOW.

UNDER extremely energetic management this good Exhibition was held last week. It was a wonderfully nice chicken Show, and the promoters deserved their success, for they worked with a will, and had much to contend against. The two Secretaries and Mr. Fred. Wiagg and Mr. Raynor worked like Trojans, and they won on all sides the good opinions of exhibitors, judges, reporters, and the public. The feeding was good, the pens were well arranged, the cards were put up speedily, the catalogues were ready. The arrangements, in fact, were admirable, and we hope we may find this Exhibition for many years to come a prosperous one. The birds were ranged in two quadrangles, one within the other. In the inner one were the Bantams and Pigeons, in the outer the rest of the poultry. Mr. John Martin awarded the prizes in the Dorkings, Spanish, Malays, and Hamburgs, Mr. Teebay in the Game, and the rest of the poultry awards were made by those two gentlemen conjointly, while Mr. E. Hutton judged the whole of the Pigeons. The awards were very well received, and appeared to have been most carefully made.

Cochins were not large but good classes. The first and second Buff pullets were good in colour but coarse in head and large in comb. The cockerels were good birds, one of them the bird claimed by the present owner at Oundle. The third contained a very young but nice pullet. Mr. Swindell sent a lovely pair of chickens, but they came too late for exhibition, or must have come in somewhere. In Partridges the pullets in the first and second pens were well marked and large. The cockerel in the first-prize pen is splendid in colour and shape, but his comb bears signs of some slight recent manipulation. The second cockerel we did not care for, and his legs were feathered in a very ugly way, still they easily won their places. In Whites the first cockerel was very white and very good generally, but still quite a chicken, and the pullet with him looked old enough to be his mother, but was we firmly believe a genuine chicken. The second cockerel was very smart to look at, but under-feathered on his legs. The third pullet was much hocked, but quite honestly shown. In Blacks the first-prize pen was very lustrous, well feathered, and large for their age. Second and third very good chickens of good colour and well shaped. In Dorkings the cup went to a fine pen of Coloured chickens, but they, too, looked very matured and old, but we were assured on good authority they were honestly birds of the year. Second went to smaller but as good birds for points and colour, while third was given to a pen of mere babies. We never saw so large a class filled with such well-grown birds, and yet with specimens so full of defects. One pen was spoilt by sooty feet, another by bad claws, and another by outside spurs. In Whites only one prize was awarded for the same reason, and these had white earlobes like a Hamburg's, but they were very smart and good in carriage, save for his spurs; however, Mr. Cresswell showed the best cockerel. Silver-Greys were moderate; the first-prize pen were well a-head; the second cockerel was very good. The Dark Brahma cockerels disappointed us very much. If the leviathan breeders of Ipswich have nothing better in reserve amateurs have a splendid chance this year of carrying off the blue ribbon at the great Show in November. The first-prize bird was well grown, fair in colour and leg-feathering, but large in comb and loose in wings; second larger in comb; third wry-beaked; No. 10 (Percival) had some good points, and 11 (Lady Gwydyr) was a neat bird, and perhaps should have been placed higher considering the defects of the winners. We could have found a bird in the Selling class equal to any of the eleven competitors. Pullets were much better than the cockerels; first (Percival) we thought an improvement upon the owner's very successful pullet of last year, being larger, superior in leg-feathering, and in colour stronger, but perhaps not so perfect throughout; second a well-marked bird; third better in some points, but rather hocked. Pen 20 (Lingwood) splendid in colour and markings, which we thought entitled her to some notice. Light cockerels superior to the Darks, but not great. The competition for the first and second prizes was very close;

the second was not so juvenile in appearance as the winners, which perhaps turned the scales; third a neat bird. Pullets.—To the astonishment of all Light Brahma breeders Mr. Dean was first, second, and third. We can only say the birds deserved their positions. *Bantams*, Game, Reds a capital class (nineteen entries); first and second Black Reds, first a very stylish cockerel, hen out of condition; third very fair Browns. Any variety, first, second, and third Piles; first a beautiful-coloured cockerel in splendid trim. Pen 423 (Southwood) was out of condition—his sickle feathers were not fully grown. We thought him the most game-looking bird in the class. Blacks.—A very neat pen were first, rest fair. Sebrights a good class. In the class for single cocks a good Black Red was first that deserved mention. *Spanish* were only a middling lot, and need no comments. The second-prize pullet was perhaps as good as any one bird. In *Game* Mr. Matthews did all he could do. His birds were shown bright in plumage and in robust health. In Black Red pullets the second-prize pen was run up to £10 10s. at the sale, and bought-in we believe at that price. In the Variety cockerel class an undubbed Duckwing was first, but his wings were badly carried, as too were those of the second-prize Pile, which was otherwise a good bird of beautiful colour. The first Duckwing pullet was a good bird all round, and well in first. In *Malays* Mr. Hinton's pens were empty. The first cockerel is a smart bird, tall, and deep in colour; the second, however, was even taller, and more like the Malay shape. The pullets were all very good. In *Leghorns* a nice pen of Whites won first. They were shown in good plumage, and seem to be in no way worse for their journey across the ocean. The cock has a large but very firm and good comb. The third went to Browns, a pretty pen, but the cock's tail was rather too high we thought. In *Orpingtons* the collection was very good, the cup pen large and good in heads; the third-prize pullet too was very black and large in crest. The second in this class was a pen of nice *La Fleche* chickens. In *Houdans* we saw nothing up to former years' birds. We liked the first cockerel pretty well and the second pullet. *Polands* mustered well. In Spangled a good pen of Golds were first, while Silvers took second. The latter pen contained a very nice pullet. Third again to good Golds. In Blacks the first were large and well matured, in fact the cockerel looked quite old. He had a loose crest, but it was white as snow. The second pen contained a wonderfully nice pullet, with a beautiful crest. Her mate was also extremely good. The third were very young but most promising. In *Hamburgs* the quality was capital, and most of the best yards had a try for the good prizes. The second Gold-pencilled cockerel had a lovely tail, but the pullet with him was not up to him, and here the markings of the first-prize bird pulled the pen in first. In Silver-pencils Mr. Kelleway had two good cockerels, but very poor pullets with them. The first pullet was very good, and beautifully pencilled upon the breast and tail. In Golden-spangles the first-prize pen also took the cup; they were a good pair, the pullet perhaps the best. The third pullet we liked very much, but she had an older appearance than the others. In Silver-spangles the first cockerel was very perfect in tail and markings. The third pullet we liked very much indeed also. In Blacks the first were the smartest pair as a pair; but the third cockerel as one bird was our fancy, but his companion was a mere baby. In the Variety class a very good pen of Silky chickens made their debut in the show pen and won the cup; but we were sorry to see the cockerel losing his leg feathers on the third day, from the incarceration we conclude. The second prize also went to good Silky chickens, the cockerel especially fine in crest. The third went to small and very yellow Sultan chickens. Mr. Bigg sent a nice pair of Sultans, but they had ruined each other's plumage by fighting in the basket; 295 contained a pen of Muffed Silkies, and very ugly they were in our eyes. The Sale classes were large, but even good birds failed to sell. The *Waterfowl* were very good, Rouen especially. In Blacks the competition was very keen, and we think it was a toss-up which of the three prize pens were most deserving of first. In the variety Duck class Mr. Leno had a lovely pair of Brazilian Teal. They are very pretty, and have a spot like a Peacock's "eye" upon them, but they were in a bad light, and failed to catch the Judge's eye. The *Geese* and *Turkeys* were large and very good.—W.

## PIGEONS.

Next to the arrangement of the birds, which was excellent, the attendance to them was good. The food was mixed and very good.

First on the list were Carrier cocks, and these were a capital lot. The first-and-cup for the Carrier section a well-known Dun; second and third Reds. Hens, first and second Duns, and third Black; highly commended a Black, with very good eye-wattle, but poor beak-wattle. Many of the Pouters were in very bad feather, and not at all fit for the show pen. In cocks Blue or Black, first was a Blue in grand order, second Black, a better bird no doubt if in show trim; third also Blue. Hens, first a smart Blue; second and third also Blues. Mr. Thornton's birds were unfortunately too late for competition. In the next

class first was the best blown bird in the Show, but moulting and bare on the shins to some extent; second and third Whites, which were in rather bad feather. Mr. Byford's birds throughout the Show were very late in feather. In hens was the gem of the Show in the shape of a White, which was as perfect as could be, and to which the cup was awarded. *Dragoons* Blue or Silver were a fair class, the majority being birds of the medium-wattled kind, which we hold are the correct thing; first was a Silver with black bars, rather large, but otherwise good; second and third Blues, the third the most perfect-headed bird in the Show, but rather light on thighs. Any other colour were first-and-cup a Yellow, not of the deepest colour, but most perfect in head; second a Grizzle, rather inclining to the London style; and third a fine-coloured Yellow, but too red on the cere. Antwerps were a good lot, and mostly quite up to the demands of the schedule—viz., Short-faces, which is a case of rare occurrence; first was a wonderful Red Chequer; second also of that colour, but not well filled-up over the beak; and third a good Silver Dun. Almonds were a nice lot, and the cup for the next section was awarded to a cock; and a capital hen was placed second. Any other colour was made up of Kites, Whole-feather, and Agates, head properties mostly ruling the awards. Barbs were not numerous, but some were very good. In cocks first was a wonderfully square-headed Black, but out of feather; and in hens Mr. Yardley won with his well-known champion. Fantails were a good lot; the second-prize winner a nice Blue, and the rest all Whites. Jacobins were two good classes, the gem of the collection being a White in the Variety class; but some good Blacks were too late for competition. Turbits a grand class, and to one who had made these almost the study of a lifetime were quite a treat, for although many birds were foul-thighed, and some not at all, as they should be in spike and mane, yet there were some as near perfect as possible; first and second Black, and third Yellow. Magpies very nice; first Red, a little large, and second a pretty little Black, not quite ready for high competition. In the Variety class Mr. Fulton won the lot, as also the cup for the section, with a good White African Owl, Black Trumpeter, and Blue English Owl. The Sale classes were large, but with the exception of the winners there were not many good lots. Mr. Fulton won the point cup.

POULTRY.—*BRAMMAS*.—*Dark*.—Cockerels.—1, H. Lingwood. 2, R. P. Percival. 3, C. Holt. *vhc*, Lady Gwydyr. *Pullets*.—1 and Cup, R. F. Percival. 2, Newham & Manby. 3, G. S. Pearson. *vhc*, T. Fye. *Light*.—Cockerels.—Cup and 1, R. P. Percival. 2, T. A. Dean. 3, G. C. B. Breeze. *Pullets*.—1, 2, and 3, T. A. Dean. *COCHINS*.—*Cinnamon and Buff*.—Cockerels.—1 and 2, Mrs. A. Tindall. 3, A. Darby. *Partridge*.—Cockerels.—1, Cup, and 2, Mrs. A. Tindall. 3, A. Beaumont. *White*.—Cockerels.—1, Mrs. A. Tindall. 2, Rev. R. S. Woodgate. *Any other variety*.—Cockerels.—1, Lady Gwydyr. 2 and 3, A. Darby. *vhc*, H. J. Storer. *DORINGS*.—*Coloured*.—Cockerels.—1 and Cup, H. Lingwood. 2, T. C. Burnell. 3, H. Wynne. *Silver Grey*.—Cockerels.—1 and 2, T. C. Burnell. *Any other variety*.—Cockerels.—1, R. A. Boissier. *SPANGLED*.—*Black*.—Cockerels.—1, J. Thresh. 2, H. Beldon. 3, R. Newbitt. *GAMPS*.—*Black-breasted Red*.—Cockerel.—1, S. Matthews. 2, G. H. Fitz-Herbert. 3, J. Cock. *Pullet*.—1, S. Matthews. 2, Hon. and Rev. F. Dutton. 3, G. H. Fitz-Herbert. *Brown-breasted Red*.—Cockerel.—1, S. Matthews. 2, J. Cock. 3, W. Perrin. *Pullet*.—1, Cup, and 2, S. Matthews. 3, W. Clough. *Any other variety*.—Cockerel.—1 and Cup, S. Matthews. 2, H. Beldon. 3, E. Winwood. *Cockerel*.—1, S. Matthews. 2, E. Winwood. 3, G. H. Fitz-Herbert. *Malays*.—Cockerel.—1 and Cup, T. Lecher. 2, H. A. Fairlie. 3, R. Hawkins. *Pullet*.—1, T. Lecher. 2 and 3, A. Smith. *HAMBURGS*.—*Gold-pencilled*.—Cockerels.—1, J. Smith. 2, J. Long. 3, Duke of Sutherland. *Silver-pencilled*.—Cockerels.—1, Duke of Sutherland. 2, J. Long. 3, H. Beldon. *Gold-spangled*.—Cockerels.—Cup and 1, H. Pickles. 2, T. E. Jones. 3, H. Beldon. *Silver-spangled*.—Cockerels.—1, H. Beldon. 2, Duke of Sutherland. 3, J. Gee. *Black*.—Cockerels.—1, C. Sidgwick. 2, H. Pickles. 3, J. Long. *POLANDS*.—*Gold and Silver-spangled*.—Cockerels.—1, P. Unsworth. 2, G. C. Ains. 3, W. H. Silver. *Any other variety*.—Cockerels.—1, Duke of Sutherland. 2, J. Fearnley. 3, T. Norwood. 3, P. Unsworth. *HODDANS*.—Cockerels.—1, J. N. Flemming. 2, S. W. Thomas. 3, Miss A. Sharpe. *FRENCH FOWLS*.—*CHICKENS*.—1 and Cup, W. F. Upsher. 2, H. Stephens. 3, Rev. C. C. Ewbank. *LEGHORNS*.—Cockerels.—Cup, 1, and 2, R. R. Fowler. 3, A. Kitchen. *ANY OTHER VARIETY*.—Cockerels.—Cup and 1, Rev. R. S. S. Woodgate. 2, O. E. Cresswell. 3, W. H. Copplestone. *SELLING CLASS*.—*Any variety except Bantams*.—Cockerel.—1, J. Swinson. 2, Lady Gwydyr. 3, S. Levett. *Pullets*.—1, S. Levett. 2, M. Gilbert. 3, C. Carr. *GAME BANTAMS*.—*Black-breasted and other Reds*.—Cockerels.—1 and Cup, G. Hall. 2 and 3, J. N. Cockshaw. *Any other variety*.—Cockerels.—1, G. H. Fitz-Herbert. 2, F. Steel. 3, J. N. Cockshaw. *BANTAMS*.—*Black or White*.—Cockerels.—1, Cup, and 2, C. J. Illingworth. 3, F. C. Davis. *Gold and Silver Sebrights*.—Cockerels.—1, Cup, and 2, M. Leno. 3, J. Walker. *Any other variety*.—Cockerels.—1, Mrs. Griggs. 2, Rev. R. S. S. Woodgate. 3, Mrs. J. Longe. *Game*.—Cockerel.—1 and Cup, G. Hall. 2, F. Steel. 3, J. N. Cockshaw. *Selling Class*.—Cockerels.—1, W. Holmes. 2, Miss Unsworth. 3, E. Holland. *Ducks*.—*White Aylesbury*.—1 and Cup, T. Sear. 2, Dr. E. Snell. 3, J. K. Fowler. *Rouen*.—1, F. G. S. Rawson. 2, J. Gee. 3, P. Unsworth. *Black East Indian*.—1 and Cup, J. J. Malden. 2, S. Burn. 3, S. Sainsbury. *Any other variety*.—1, Cup, and 2, J. Walker. 3 and *vhc*, M. Leno. *SELLING CLASS*.—1, Mrs. C. Berners. 2, T. Sear. 3, Miss E. A. Eeles. *GEES*.—1, Dr. E. Snell. 2, J. K. Fowler. 3, J. Everett. *vhc*, W. T. Brackenbury. *TURKEYS*.—1 and 2, H. J. Gannell. 3, R. Everett.

PIGEONS.—*CARRIERS*.—*Black or Dun*.—Cock.—1, Cup, 2, and 3, R. Fulton. *vhc*, R. Fulton. *Hen*.—1, 2, and 3, R. Fulton. *vhc*, R. Cant. *Any other colour*.—Cock.—1, 2, and *vhc*, R. Fulton. 2, W. G. Hammock. *Hen*.—1, R. Fulton. 2 and 3, W. G. Hammock. *POUTERS*.—*Black or Blue*.—Cockerel.—1, 2, and 3, R. Fulton. *vhc*, A. P. Byford. *Hen*.—1, 2, and 3, R. Fulton. *Any other colour*.—Cock.—1, T. Herriott. 2 and *vhc*, R. Fulton. 3, A. P. Byford. *Hen*.—1, Cup, 2, and 3, R. Fulton. *vhc*, A. P. Byford. *DRAGONS*.—*Blue or Silver*.—Cock or *Hen*.—1, 2, and *vhc*, R. Fulton. 3, Hon. W. Sugden. *Any other colour*.—Cock or *Hen*.—1 and Cup, R. Woods. 2 and 3, R. Fulton. *vhc*, J. Chandler. *ANTWERPS* (Special flying class).—*Short-faced*.—Cock or *Hen*.—1, T. Kendrick. 2, H. Yardley. 3, C. F. Copeman. *Homing*.—Cock or *Hen*.—1, C. Chandler. 2, E. L. Oxborough. 3, W. Rayner. *TUMBLERS*.—*Almond*.—Cock or *Hen*.—1, Cup, 3, and *vhc*, R. Fulton. 2, H. Yardley. *Any other variety*.—Cock or *Hen*.—1, 2, and 3, R. Fulton. *vhc*, R. Cant. *BARBS*.—Cock.—1, 2, and 3, R. Fulton. *Hen*.—1, H. Yardley. 2 and 3, R. Fulton. *FANTAILS*.—Cock or *Hen*.—1 and 3, T. F. Lovelidge. 2, W. McCandlish. *JACOBS*.—*Red or Yellow*.—Cock or *Hen*.—1, 2, and 3, R. Fulton. *vhc*, G. Hardy. *Any other colour*.—Cock or *Hen*.—1, T. W. Swallow. 2 and 3, R. Fulton. *TURBETS*.—Cock or *Hen*.—1, O. E. Cresswell. 2, R. Woods. 3, R. Fulton. *vhc*, G. Hardy. O. E. Cresswell. R. Woods. *MAGPIES*.—Cock or *Hen*.—1, G. H. Gregory. 2, H. W. Webb. 3, H. Jacob. *ANY OTHER*

**VARIETY.—Cock or Hen.**—Cup, 2. 3. and *vhc.* R. Fulton. **SPECIAL SELLING CLASSES.**—*Price not to exceed £3.*—*Cock or Hen.*—1. H. W. Hale. 2. R. Woods. 3. T. Roper. *vhc.* G. G. Sykes. A. P. Byford. *Price not to exceed £1 10s.*—*Cock or Hen.*—1. A. & W. H. Silvester. 2. A. P. Byford. 3. Brothers Popplewell. *vhc.* H. W. Webb. A. P. Byford. *Price not to exceed £8.*—*Cock or Hen.*—1. C. Bevan. 2. G. Shepherd. 3. T. E. Hainsworth.

## FARNWORTH POULTRY SHOW.

The twelfth annual Show was held at Farnworth on the 21st ult. In poultry there were eight silver cups, and £2, £1, and 10s. in each class, and, as a matter of course, this was well responded to, there being 209 pens, and many excellent birds were shown. *Dorkings* six pens and very good. In *Brahma* chickens the winners were all of the Dark variety, the cup going to old birds. *Cochins* had four classes with only twenty entries, but the birds were good. *Game* four classes with twenty-nine entries. The Black Reds were uncommonly good, and the first in grand order. Brown Reds first, a very raw but promising cockerel. Both first and second pullets were of rare quality. In the Variety class first and cup for best pen went to a stylish pair of Piles, birds of this year. *Spanish* were young, and quite the best class we have seen this season. *Hamburgs* were well represented, the cup for this section going to Golden-pencilled chickens. Silver-pencils and spangles were very good and in nice order, but the same cannot be said of the Golden-spangles, the first and second of which, though best in points, were decidedly out of order, and it is a pity they should continue to be shown in such a state, as it is spoiling valuable birds. *Bantams* might be given more classes as paying their way by far the best of all, there being thirty-five in four classes. *Rouen Ducks* were an extraordinary class, and the prizes and cup carried off by one exhibitor. The day was very fine and warm, the poultry in open pens with solid backs, and the Show well attended.

**POULTRY.—DORKINGS.**—*Chickens.*—Cup and 1. J. Walker. 2 and 3. J. Cople. **BRAMA** POOTRAS.—Cup, 1. 2. and *vhc.* T. F. Ansell. 3. Mrs. A. Tindall. *Chickens.*—1 and 2. R. Percival. 3. T. Beardsworth. **COCHINS.**—*Cinnamon* or *Buff.*—1. E. B. Percival. 2. A. Darby. *Chickens.*—1. Mrs. A. Tindall. 2. R. Percival. 3. A. J. E. Swindell. *Partridge Feather.* or *any other variety.*—1. R. Percival. 2. Mrs. A. Tindall. 3. J. K. Fowler. *Other variety than Cinnamon* or *Buff.*—1. T. Stretch. 2. R. Percival. 3. T. F. Ansell. **GAME.**—*Black-breasted Red.*—*Chickens.*—1. J. B. Pratt. 2. T. P. Lyon. 3. M. Jowett. *Brown-breasted Red.*—*Chickens.*—1. C. W. Brierley. 2. H. Beldon. 3. G. F. Ward. *Any other variety.*—*Chickens.*—Cup, H. Beldon. 2. T. Dyson. 3. J. Halsall. *Any colour.*—*Cock.*—1. J. Halsall. 2. H. E. Martin. 3. T. G. Spantise. *Chickens.*—1. H. Beldon. 2. J. Albridge. 3. J. Pitt. **HAMBURGS.**—*Golden-pencilled.*—*Chickens.*—Cup and 1. J. Long. 2. G. & J. Duckworth. 3. H. Beldon. *Silver-pencilled.*—*Chickens.*—1. H. Beldon. 2. G. & J. Duckworth. 3. G. & J. Green. *Golden-spangled.*—*Chickens.*—1 and 2. G. & J. Duckworth. 3. T. Scholes. *Silver-spangled.*—*Chickens.*—1. H. Beldon. 2. G. & J. Duckworth. 3. J. Long. **POLANDS.**—1 and 2. H. Beldon. 3. P. Unsworth. **ANY OTHER VARIETY.**—1. H. Beldon. 2. C. Sidgwick. 3. W. J. Upsher. **SELLING CLASS.**—*Chickens.*—1. R. Sutton. 2. J. Fearnley. 3. T. Wakefield. **BANTAMS.**—*Game.*—*Chickens.*—Cup and 1. W. F. Addie. 2. J. Nelson. 3. R. Brownley. *Cock.*—1. J. Nelson. 2. R. Newbitt. 3. W. Baskerville. *Any variety except Game.*—1. J. W. Crowther. 2. and 3. M. Leno. **DUCKS.**—*Crosses.*—Cup, 3. and 3. W. Evans. *Dylebury.*—1 and 3. J. Walker. 2. J. K. Fowler. *Any other variety.* or *Ornamental Waterfowl.*—1. J. Walker. 2. C. W. Brierley. 3. M. Leno. **GESE.**—1. J. Walker. 2. J. K. Fowler. 3. J. Birch. **TURKEYS.**—1. J. Walker. 2. W. Gertard. 3. J. Brookwell.

**JUDGES.**—Messrs. Teebay and Fell.

## BRISTOL SHOW OF CANARIES, &c.

This was held on the 26th ult. The following is a list of the awards:—

**CANARIES.—NORWICH.**—*Clear Yellow.*—*Cock or Hen.*—1 and 3. J. Athersuch. 2. C. J. Salt. *Clear Buff.*—*Cock or Hen.*—1 and 2. J. Athersuch. 3. C. J. Salt. *Evenly-marked Yellow.*—*Cock or Hen.*—1. C. J. Salt. 2 and 3. J. Hopkins. *Evenly-marked Buff.*—*Cock or Hen.*—1. J. Hopkins. 2. C. J. Salt. 3. J. Athersuch. *Ticked or Unevenly-marked Yellow.*—*Cock or Hen.*—1. J. Athersuch. 2. J. Adams. 3. Brown & Gayton. *Ticked or Unevenly-marked Buff.*—*Cock or Hen.*—1. J. Adams. 2. J. Athersuch. 3. Brown & Gayton. *Crested Yellow.*—*Cock or Hen.*—1. J. Hopkins. 2. J. Athersuch. 3. G. E. Russell. *Crested Buff.*—*Cock or Hen.*—1. S. Stratford. 2. J. Hopkins. 3. J. Adams. **LEICESTER.**—*Golden-spangled.*—*Cock or Hen.*—1 and 2. T. M. Reid. 3. S. Bunting. *Silver-spangled.*—*Cock or Hen.*—1. Cleminson & Ellerton. 2. C. J. Salt. 3. W. Evans. *Golden-spangled with Broken Caps.*—*Cock or Hen.*—2. C. J. Salt. 3. Cleminson & Ellerton. *Silver-spangled with Broken Caps.*—*Cock or Hen.*—1. W. Evans. 2. C. Greenwood. 3. C. J. Salt. **CINNAMONS.**—*Yellow.*—*Cock or Hen.*—1. J. Adams. 2. J. Athersuch. 3. W. Rice & Co. *Buff.*—1, 2, and 3. J. Adams. **ANY OTHER VARIETY.**—1. C. J. Salt. 2. J. Baker. 3. J. Hopkins.

**MULES.—GOLDEN and CANARY.**—*Variegated or Clear Yellow.*—*Cock or Hen.*—1. C. J. Salt. 2. J. Stevens. 3. Stroude & Goode. *Variegated or Clear Buff.*—*Cock or Hen.*—1 and 2. C. J. Salt. 3. J. Stevens. **ANY OTHER VARIETY.**—*Cock or Hen.*—1. R. Pearson. 2. Mrs. J. T. Holmes. 3. C. J. Salt. **FOUR BIRDS IN ONE CAGE.**—*Any variety previously mentioned.*—2 and 3. J. Adams.

**BRITISH BIRDS.—BULLFINCH.—*Cock or Hen.*—3. J. Yallop. **GOLDFINCH.—*Cock or Hen.*—1. J. Athersuch. 2. S. Roberts. 3. S. Bunting. **LINNET.—*Cock or Hen.*—1. W. C. Roberts. 2. S. Roberts. 3. R. G. Keck. **WREN.—*Cock or Hen.*—2. R. J. Troake. 3. T. L. Liny. **SONG THRUSH.—*Cock or Hen.*—1. W. Carrick. 2. C. J. Salt. 3. E. Gardiner. **ANY OTHER VARIETY.—*Cock or Hen.*—1 and 2. E. **ROSS POULTRY SHOW.**—In the schedule of this Show are introduced some new prizes—viz., for dead poultry trussed for

the table, to encourage the growing of good table birds, produced of course by crossing purely bred fowls, dressed Ducks, honey, butter, &c. The Judges are Mr. E. Hewitt for poultry, and Mr. H. Allsopp for Pigeons.

## THE POWDERED OWL, MAHOMET, AND DAMASCENE PIGEONS.

It is mentioned at page 301 of Mr. Fulton's "Book of Pigeons," that the late Mr. Matthew Wicking "was the first to invent, or produce, or introduce the colour known as powdered blue." I believe Powdered Blue Owls were in existence last century, but Mr. Wicking may have produced them for himself. Mr. Moore in the "Columbarian" (1735) says of the Owl, "This Pigeon is in make and shape like the former (the Turbit), except that the upper chap of its beak is hooked over like the Owl's, from whence it has its name. Its plumage is always entirely white, blue, or black." He says nothing as to the blue being in any way different from other blue Pigeons, so that I would suppose Powdered Blues were not known to him. The colours of the Owl in his day are the colours of the African Owl now, except as to Pied Blues and Blacks, the result of breeding white and coloured birds. Coming to the Mahomet, Moore says, "This Pigeon is no more in reality than a White Barb," and he then describes how it gets the name of the Mahomet. Thirty years later, in 1765, appeared the "Treatise on Pigeons," dedicated to John Moore. The author, after quoting Moore's description of the Mahomet, says, "So far Mr. Moore, and I think he has extremely well accounted for its being so called; but it is the opinion of many fanciers that the bird called a Mahomet is nearly of a cream colour, with bars cross the wings as black as ebony; the feathers very particular, being of two colours, the upper part or surface of them appearing of a cream, and underneath a kind of sooty colour, nearly approaching to black, as are likewise the fine feathers and even the skin, which I never observed in any other Pigeons but these; its size much like that of a Turbit, with a fine gullet, and in lieu of a frill the feathers rather appear like a seam; the head is short, and inclined to be thick; hath an orange eye and a small naked circle of black flesh round the same, and a beak something resembling that of a Bullfinch, with a small black wattle on it." Now, referring to Mr. Ludlow's portrait and Mr. Caridia's description of the Damascene in Mr. Fulton's new book, there is no doubt that the Mahomet of 1765 and Damascene of to-day are identical. The head, beak, gullet, and seam all tell of its relation to the Owl tribe, and no other Pigeon I know of would do so well to cross with the Owl; in fact, I think that between 1735 and 1765 the cross was made, for the author of the Treatise says of the Owl, "The blue ones should have black bars cross the wings, and the lighter they are in colour, particularly in the hackle, the more they are valued." Is not this the description of a Powdered Owl? The Mahomet or Damascene is the powdered colour to the highest degree. I lately mentioned this idea of the origin of the Powdered Owl to Mr. Caridia, and he agreed with me. He says, in his description of the Damascene, "This variety, in my opinion, is one of the most useful for experimental purposes."

Mr. Wicking may have discovered a remnant of the breed of Powdered Owls, being a very keen fancier, but what I think more likely is that he got hold of the Damascene or Mahomet, and made the cross himself. He may have had the very pair of birds mentioned by Mr. Brent. In Mr. Brent's book, page 26, he gives the description of the Mahomet from the Treatise of 1765, but says he does not remember having seen any such birds. Again, at page 109 he gives the points of the Mahomet as follows:—"Black wattle and cere; sooty skin and down; seam on the breast; soft silver colour [a more true description than cream]. No harm in offering a class, but I fear the bird is extinct." However, after he so wrote he appears to have seen a pair of these Pigeons, for I find in Mr. Tegetmeier's book of Pigeons, page 138, and in Eaton's treatise of 1853, page 102, the following:—(Brent). "This (the Mahomet) is one of the varieties of fancy Pigeons with which I have but a very slight acquaintance, having only once seen a pair at a London dealer's, and their appearance gave me the idea of a cross between an Owl and a Barb Pigeon; nevertheless, their seam and black wattle, cere, and skin I consider sufficient distinctive peculiarities to give them a place among fancy Pigeons as a separate variety. It is very probable that the present relations existing between this country and the Sublime Porte may cause the introduction of other varieties of Pigeons from the East." And has not Mr. Brent's idea come to pass in the introduction by that grand Pigeon-fancier, Mr. H. P. Caridia, of the beautiful gems the Turbitines, Satinettes, Blondinettes, &c., from Asia Minor? Who so likely as Mr. Wicking to get hold of the pair of Mahomets seen by Mr. Brent at the London dealer's? He might have lost one of the pair before they were acclimated, and the most likely match for the survivor would be a Blue Owl. Mr. Fulton says, "Great was the surprise of many London fanciers when the new and startling beautiful colour came upon the stage. The first we ourselves saw was about the year 1854. The colour

was produced—very likely partly by some lucky chance—by crossing Blues and Silvers, and it is most singular that, so far, crossing it with any of the small foreign specimens seems to overpower it, and it dies out." If my theory is correct the Powdered Owl is only after all half-bred as regards powdering, and therefore it is no wonder the colour goes when crossed with the dusky Blue African. But if some experimental breeder would make the cross anew between the Damascene or Mahomet and the Blue African better results might follow, and certainly the produce would be better in head and beak than any Powdered Owls I have seen. Mr. Fulton says, "It was well put once in our own hearing by that old and much-respected fancier Mr. Esquilant, who remarked that the only certain way of seeing a really true-bred English Owl now was to see a Powdered Blue." This is as much as to say that other English Owls than "Powdered" birds have been crossed with the African breed to improve them. No one after looking through Mr. Fulton's book will need to be told that Mr. Ludlow is not responsible for the colouring of the plate of English Owls. Someone has made a mess of it. The publishers would do well to publish a fresh plate, as it mars the whole book.—JAMES C. LYLELL.

### OXFORD POULTRY SHOW SCHEDULE.

The fifth Exhibition is at hand, and Oxford once more presents to the public a menu even more tasty and more comprehensive than ever. The Committee are the same as in past years; one of them, however, since last we were there has been returned Mayor for the city. We cannot attempt to criticise the classes and prizes offered; we only urge all to send by the next post for a schedule, as they will find something to suit even the most fastidious exhibitor. There are fifty-five cups or pieces of plate; there are handsome local prizes; there are four good prizes for undubbed Game cockerels; there is a £10 prize for the best Black Red cockerel; there are classes for Brown and for White Leghorns; for White-crested Black Polands, for Silkies, for Malays, for Black Ducks; there are seven classes for Bantams; there are seventeen classes for Dragoons; there is a Variety class, and nothing left to go in it. There is, in fact, a splendid prize list, a good Committee, and every prospect of a splendid show. Not only should fanciers exhibit, but fanciers should attend, for the Oxford Committee promise them a right hearty welcome, and beg us to say that everyone will be treated alike, and that there will be no partiality and no favour. Entries posted on Sunday will be in time, and all birds must be in the Show on October 23rd by midnight. The whole of the prize pens will be put up to auction on the usual terms, and all exhibitors of four pens will have a free pass. Enter early, enter largely, enter all you can, and make this important Exhibition the great success it deserves to be.—W.

### GOLDFINCHES.

In the issue of September 21st, in reply to "C. G. B.," we briefly alluded to the Goldfinch known as the "Cheverel," which possesses the white mark on the throat. By no other sign is the bird distinguished from other Finches, and this may be accepted as an answer to your question, "What are the proper points of a 'Chevalier' Goldfinch?"

The Goldfinch proper (not a "Cheverel") is judged for the following points:—Head bright scarlet red, showing no white speck or mark on the throat, the back part of the head and down the sides of the neck deep black; beak large and pointed; breast, the centre white, with the sides of the breast and flanks pure brown; back rich brown; cheeks and sides of the neck nearest the face white; large covert feathers well marked with pure yellow; feathers close, and general appearance smart, with pinion feathers in wings and tail tipped with white. But concerning other varieties Bechstein says, "The characteristics which mark the following varieties are thus:—The Goldfinch with the yellow breast; the White-headed Goldfinch; the Black-headed Goldfinch (of this variety four were taken out of the same nest); the White Goldfinch; the Black Goldfinch. These (the latter) are either entirely black, which is caused by age or being fed upon hemp, or they retain the yellow spot upon the wings. The last will sometimes happen in the cage. . . . Those Goldfinches which become black before old age resume the colour after moulting, but then do not usually live much longer."

With respect to the Black Goldfinch it is no uncommon occurrence to find such at bird exhibitions—the Crystal Palace Show in particular—and where also, two years ago, a most lovely pure white Goldfinch in beautiful condition was exhibited by Mr. W. H. Allcorn of 31, Great St. Andrew Street, London. I may state that I have in my possession a stuffed specimen of a Goldfinch of a dove colour, with the yellow markings in the primary wing feathers, but possessing only one small scarlet-red feather in the face of the bird, which in an ordinary specimen would be bright scarlet-red surrounding the base of the beak. The bird, with three others, was taken alive from a nest in Gloucestershire

some ten years ago, and given to me by Mr. G. Cummings of Gloucester.

Bechstein further remarks—"The tail should be slightly forked and black, the two, and sometimes the three, first pinion feathers having a white spot in the centre of the inner web, and the rest with white tips. The female is a little smaller, not so broadly and beautifully red about the beak; the chin brownish; the cheeks intermixed with bright brown; the smaller coverts of the wings brown, and the back of a deeper dark brown. The size and even deficiency of some of the white tips of the pinion feathers cannot be taken as a distinguishing characteristic between the sexes, as some birdcatchers assert, and as little may we adopt their opinion that the size and number of these spots constitute different varieties. These distinctions are accidental, and depend on the state and age of the bird."

Some Goldfinches are larger than others and are termed Pine Goldfinches, whilst the smaller birds are called Garden Goldfinches, and are assumed to be bred only in gardens; but Bechstein remarks, "these differences are quite imaginary," and assumes the first birds hatched are usually the largest, which accounts for the variation in size of the same species of birds.

Broderip says that "the *débonnaire* Goldfinch builds one of the most elegant nests that our Finches produce: moss, lichens, wool, and grass, artistically intertwined, form the outside of the fabric, which is generally hidden in a quiet orchard or secluded garden, where, in the midst of some evergreens—an arbutus, perchance—it is protected from the prying eye by the compact leafy screen of the well-grown healthy shrub." The Rev. F. O. Morris says, "the Goldfinch builds in orchards and other trees;" and Yarrell remarks that "the Goldfinch builds a very neat nest, which is sometimes fixed in an apple tree or pear tree."

Many amateur bird-breeders make much ado about possessing a "Cheverel" Finch for breeding purposes, and such birds are generally estimated at greater value. Some bird-dealers assert that the variety termed a "three-by-six" is the bird proper for breeding with. Such are known by the three outer tail feathers upon each side being mottled with white in the inner web, whilst the six centre tail feathers are dark. But to me the matter is of little consideration so that I possess a Finch of an ordinary kind that will breed.

It has often been a matter of surprise to find a want of knowledge existing in rural districts with respect to one of our choicest-plumed British birds—the Goldfinch, which is so ignorantly confounded with the Yellowhammer, which latter specimen is frequently and persistently asserted to be the Goldfinch, whilst master Goldie is dubbed a "Red Linnet."—GEORGE J. BARNESBY.

### BEES' EGGS—TIME REQUIRED FOR HATCHING.

The time, from the egg, required for the development of queen and worker bees is a point of much importance in practical bee-culture. The following experiments to determine it are taken from my private journal begun in 1862:—

July 24th, 1863.—I at 12 A.M. took a Ligurian queen from a large stock and put her with bees enough to form a strong nucleus, into a box having six small combs. The two central frames were filled with worker comb built the same season, from which nearly all the brood had just hatched, the others were well supplied with both honey and pollen. 2½ P.M.—Saw no eggs, queen upon a central comb, evidently preparing to lay. 3½ P.M.—A few eggs laid. Judged that the queen began laying about 3 P.M. 25th, 12 A.M.—Removed the queen. 28th, 9 A.M.—One queen cell begun. The larvae plentifully supplied with jelly.

August 1st, 6 A.M.—Five or six worker larvae apparently just sealed over (capped), one queen cell almost capped. 7 A.M.—One queen cell capped. The nucleus has been kept strong in bees, and all the other conditions have been favourable. All of the eggs, about four hundred in number, were laid in one of the new worker combs, and although the interval between the laying of the first and last egg could not have exceeded twenty-one hours, the development of the larvae in different cells is more irregular than might be expected. 12 A.M.—Another queen cell capped. 8th, 5 P.M.—A queen just hatched. For some hours after this nucleus was made and examinations were made at intervals not exceeding half an hour. While engaged in these experiments a queen hatched in each of two strong stocks, between three and four hours less than ten days after the stocks were unqueened. 10th, 10 P.M.—All the queens but one had hatched and were removed. 11th, 5 A.M.—The last queen has hatched, her pale appearance showing that she could be only a few hours old. Her cell was on the edge of the comb, and the egg was probably among those last laid. 12th, 5 P.M.—Two workers hatched. The examinations to-day have been made at intervals of not more than half an hour. 13th, 5 A.M.—Workers hatching freely. 14th. All the bees in the central cells had hatched, there being only a rim of two or more cells wide still unhatched. 15th, 6 A.M.—Thirty yet unhatched. 10 A.M.—Twenty all in the extreme outside cells of the circle of cells which contained the eggs. 5 P.M.—Thirteen. 16th, 6 A.M.—Five unhatched. 3 P.M.—The last worker gnawing its way out.

During the whole time while these experiments were being made the thermometer ranged from over 70° to over 90°; and as the colony was never opened when it was not above 90°, and seldom when it was not nearer 80°, there seems no probability that the development of the larvæ could have been perceptibly checked.\*

No experiments were made by me to determine whether black and Ligurian bees may not slightly vary in the time of their development.

My experiments on drone eggs unfortunately were not so successful, and determined nothing more definite than that drones may hatch in about twenty-four days from the egg.

The experiments above detailed warrant the following conclusions:—1. Bees may begin to build a queen cell in less than four days after an egg has been laid in a worker cell.

2. Queen and worker larvæ may have their cells capped at least seven days and fifteen hours after the eggs were laid.

3. A perfect queen may hatch in fifteen days and two hours from the time the egg was laid in a worker cell.

4. A queen may hatch in three or four hours less than ten days after the stock was unqueened.

5. A perfect queen may not hatch, even under very favourable circumstances, until nearly sixteen days and a half have elapsed since the egg could have been laid in a worker cell.

6. A worker may hatch in nineteen days and two hours from the egg, and there may be an interval of precisely four days between the development of a queen and a worker.

7. While most of the workers may hatch in less than twenty-one days from the egg, some may not hatch before the twenty-third day, so that in the same colony there may be a difference of more than three days in the time taken to develop workers from the egg.

8. The eggs of the queen bee do not therefore necessarily hatch at precise intervals from the time they were laid, any more than the eggs placed at once under the domestic hen hatch simultaneously.—L. L. LANGSTROTH, *Oxford, Ohio.*

### BEES COLOURING WAX.

THERE is a statement by your esteemed correspondent Mr. Pettigrew in your last number which I cannot let pass unchallenged. Mr. Pettigrew says that bees "always temper the colour of the lids of brood cells to correspond with the colour of combs." Now, my experience has been that bees never cap brood cells with new wax, but as the edges of the cells are of extra thickness, and contain sufficient material to form a cap, they simply draw out the edges, and so cover over the cell. We know that the dark colour of old comb arises from impurities, so I cannot conceive that bees should dirty the caps of the brood cells (apparently the only part that is "tempered," according to Mr. Pettigrew) just for the sake of uniformity of colour. It is true that bees sometimes use grey and dirty materials, but is not that because they have cut up and are using some old comb? for as soon as that is exhausted, and "before many inches are built, they use nothing but pure wax."—J. P. J.

### FEEDING SWARMS IN AUTUMN.

THE creation of stocks by feeding the bees of honey hives will, I am sure, become more common and popular year by year. The introduction of large hives tends to the adoption of this practice. I lately wrote to a friend who lives in a district in which many bees are kept and well managed, to ask if the bees of honey hives could be bought with money. His answer is to this effect, that all the hives in the neighbourhood were too heavy for keeping, and that the bees were driven from them all and their honey taken. The swarms had been united in pairs, and fed into stocks. A correspondent of this Journal has, he informs us in last week's number, been giving a united swarm 1 lb. of syrup daily, and asks how long he has to continue giving this to the hive. I think it better to give the syrup in larger doses. After the first two or three days we give 3 lbs. of syrup every night to a large swarm, and often more. A swarm of 5 lbs. of bees requires from 15 lbs. to 20 lbs. of sugar boiled in as many pints of water. Twenty pounds of sugar makes about 40 lbs. of syrup. All this should be given to a large swarm in fifteen days. If given in smaller portions less comb is built, and less food is stored up, simply because the bees consume a great deal themselves during the excitement of feeding. No writer on bees that I know has ever fully made known the great consumption of food by bees in times of excitement and hard work. A strong hive at the swarming season loses about a pound weight every night; and what is spent in the wear and

tear of a full day's work no one can tell. In creating stocks by artificial feeding it should be borne in mind that the bees have combs to build, themselves and their brood to feed, as well as store up food enough for winter. Autumn feeding, we have said again and again, should be speedily done. A fortnight ago the readers of this Journal were informed that I offered £7 10s. per 100 lbs. of condemned bees—that is 7s. 6d. per swarm of 5 lbs. The offer was accepted and the bees sent. One or two lots did not arrive safely, but the great bulk came all right. Having so many to feed at the same time we have been using dripping-tins and pie-dishes of various sizes and complexions as feeding troughs. Those that hold most syrup are the best for the bees, for I find that the swarms that have the largest doses have done better than the rest. All are doing well, but those that had the largest dishes under them are now fully fed, and about as perfect and excellent stocks as the eye of man ever looked on.—A. PETTIGREW.

### BEES SWARMING WITHOUT A QUEEN.

LAST year I had a very large swarm which I tried to prevent swarming, so as to obtain as much honey from the bees as I could. I cut out the queen cells once in every eight days, and put on one of Mrs. Farnham's non-swarmers so that the queen could not escape. The result was the bees swarmed three times and returned to the hive. The next performance was, they gathered on the hive and remained overnight, covering three sides of the hive. The next day at ten I went out to take a look at them, and it was my last look; for, while standing there viewing them, they started in a body, rose 50 feet in the air, and disappeared in thirty seconds. I opened the hive, and there was my queen all right.

This year I had a swarm become queenless; I opened the hive to see if they were building queen cells, and found in one drone comb that every cell on one side was being prepared for queens, and was supplied with queen jelly. One cell was completed, which I cut open and out came a queen as lively as a cricket. I put her in the hive, but she never laid.—M. O. HAZEN (*in Prairie Farmer*).

### OUR LETTER BOX.

LUMPS ON HEN'S TOE (*Amateur, Bury*).—If small cut them off with a sharp knife. Dairi is useful as a change of food.

FOWLS' WINGS DROOPING AND DYING (*Fire*).—They are fed too generously. Having three acres of grass to range over they need, except in days of frost and snow, only a little whole corn (no buckwheat), in the morning, and a little soft food when going to roost.

GOAT-KEEPING (*A Fifteen-years Acquaintance*).—In our twenty-sixth volume is all that we could glean about the subject. The great obstacle is the wax from Old Comb (*M. J. P.*).—The easiest way of extracting wax from old combs is by boiling them in clean water. First press the combs into little bulk, then put them into a bag made of thin towelling or cheese-cloth, tie the mouth of the bag tightly, and let all boil over a slow fire for twenty minutes. All the wax in the combs will come to the surface, and may be easily skimmed off and put through a strainer. In cleaning the utensils afterwards use plenty of soda, which destroys the adhesive power of the wax.

### METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

### REMARKS.

27th.—Very damp and dark all day; heavy shower at midnight.  
28th.—Fine at eight, rain at nine, pouring at 9.30 A.M., and very dark; mid-day fair; evening and night wet.  
29th.—Very fine morning and forenoon, but rain at 1.30, lunar halo at 9 P.M.  
30th.—Rainy and very dark all day and all night. A most miserable day. [day.  
Oct. 1st.—Dull morning, fine before noon, and very fine all the rest of the day.  
2nd.—Pleasant day though rather cool. Min. temp. fell to 37.5°.  
3rd.—A bright pleasant day, the sun at times very bright, less fine towards dusk, and slight rain in the evening.  
Atmosphere generally damp with frequent rain, temperature lower especially at the maxima.—G. J. SYMONS.

### COVENT GARDEN MARKET.—OCTOBER 4.

A QUIET trade doing, with prices inclined to be lower. The supply of Peaches has fallen off, and fair samples are now making good prices. We are still mainly dependant upon France for best Pears, the sorts now coming being Duchesse d'Angoulême, Louise Bonne de Jersey, and Beurré d'Amanlis. Kent Cobs have experienced a further fall this week.

\* On the 19th of February a queen hatched in a few hours more than twelve days, after her mother was accidentally killed while I was making some experimental examinations. The colony was a small one, the hive poorly protected, and the weather quite cold the most of the time that she was maturing. On the 22nd of November a perfectly developed queen hatched in a small nucleus in not over sixteen days from the egg. The days were quite cold and the nights generally frosty.

From observations taken near London during forty-three years, the average day temperature of the week is 59.6°; and its night temperature 49.1°.

## THE DAHLIA.

HIS noble autumn flower is not so much grown now as it was ten or fifteen years ago. In many large and pretentious gardens no Dahlias are grown, or, if they do find a place, it is not an honourable one; they are huddled away into some corner, or they fill up a gap in a shrubbery border. The Dahlia cannot be said to be a fashionable flower. It is not adapted for carpet bedding or the geometrical flower garden, although some of the dwarf flowering sorts sometimes do good service as a back row to the ribbon borders. It is not in the south of England that the Dahlia is seen to the best advantage in private gardens. In the north of England and many districts in the south of Scotland a favourable portion of the kitchen garden is not unfrequently devoted to its special culture, or a border may be specially prepared in the flower garden, where the Dahlia is made to do duty as a background flower. In either case careful culture is insisted upon. The flowers are thinned out according to their character, those varieties tending to coarseness bearing the largest number of flowers, while small and medium-sized sorts may be thinned-out to any extent. During the month of September the Dahlia is in its prime in the south, and the best flowers are exhibited about the third week in the month. It is necessary to hold the exhibitions in some parts of Scotland earlier than this, as the flowers are not unfrequently cut off by frost before that time. I have been urged to write these and the following remarks on the Dahlia from the fact that many persons grow the flower who require the aid of a few cultural notes.

By the time this appears in print the Dahlia season will be nearly over; the first frosty night makes sad havoc amongst the plants. Some growers cut the plants down and dig them up at once, but this is not desirable: a better plan is to place a spadeful of soil or any dry material round the base of the plants, and allow them to remain a week or two longer. When it is time to take the roots up the plants should be cut off about 6 inches above the ground, the roots should be carefully lifted with a fork, placing them in a sunny position with the stems downwards. This will dry them and allow all the water to drain out of the hollow stems; a large quantity sometimes finds its way in at the axils of the branches, and lodges in the stem at the crown of the plants. The labels should be firmly fastened to the stems, and the tuberous roots be placed in a shed where no frost can gain access. The roots may be placed closely together, and be covered over with dryish sand or leaf soil. They ought not to be kept quite dry, and, on the other hand, damp is almost equally injurious. It is important to have the roots well dried before storing them.

If it is intended to propagate a large number of plants, the roots may be placed in the forcing house about the end of January or early in February; but, as a rule, the middle or end of March is sufficiently early. I generally

plant the roots closely together in a box in some light soil, just covering the tubers. If the boxes can be placed in gentle bottom heat so much the better. The night temperature should be from 50° to 55°. I am not writing now for the information of trade growers, who would not be content with such low temperatures. They start their plants early and force rapidly, the object being to propagate the largest number of plants in a given time; whereas the private grower looks to the quality more than the quantity of his plants. In a week or two after putting the roots into heat the young shoots will appear, and when they are an inch or so in length they may be taken off close to the main stem, and the cuttings should be potted singly in small 60's or thumb-pots in soil composed of equal parts of leaf soil and loam, with a little sand added to it. The pots should be plunged in bottom heat either in a frame or propagating house. The cuttings will soon strike root, and when this is the case they ought to be removed to the greenhouse or heated pit. The young plants ought to be placed near the glass, as otherwise they are apt to become drawn. In a few days they may be repotted into 4 or 5-inch pots, and when fairly established be placed in a cold frame, where in mild weather the lights may be entirely removed, but covering the plants up closely when there is danger of frost. In the north it is not safe to plant out until the very last week in May, and sometimes beginning of June, but if planting is deferred so late as this the plants ought to be again potted into 6 or 7-inch pots. If they become rootbound it is certain that they cannot start into vigorous growth.

Of course the soil ought to be prepared long before planting-out time. The ground should be trenched at once, and this is an important preliminary operation. Unless the ground is rich and deeply trenched good Dahlias cannot be expected. A good manure is that from the cows and the stable-yard thrown into a heap and slightly heated. The comparatively dry hot dung absorbs the moisture of the cool cow manure, and the object in using it when in a state of fermentation is that the ammonia is absorbed by the earth instead of being wasted. I have often described the method of trenching ground and wish to avoid repetition. A good dressing of manure ought to be applied, and a thickish layer of turfy loam ought to be placed over the upper coat of dung about 6 inches below the surface; this is the more necessary when the same ground is required to grow Dahlias many years in succession. During winter it is very desirable to fork the surface of the ground over frequently in fine weather; after rains the surface becomes caked and impervious to air, but on no account ought the soil to be touched in wet weather.

We now come to the end of May or beginning of June. The ground has been well prepared, and also the plants by exposure night and day to the open air; and before planting they ought to have been in a position sheltered, it may be, from the north and east, but where the sun could shine upon them during the greater part of the day. The heights of Dahlias range from 3 feet to 5 or even 6 feet, and this must be taken into account at planting

time. Say a border has to be planted with four rows, and the plants are to be put in 3 feet apart—it must not be less than this—a line should be stretched 18 inches from the edge, the sticks should then be driven well into the ground where it is intended to plant the Dahlias, and the front-row sticks should be about 3 feet out of the ground, the next row may be 9 inches higher, and so on, which will make the back or fourth row 5 feet 3 inches. A fair-sized hole should be taken out in front of each stick, and a compost of turfy loam, a little decayed manure, and leaf soil mixed together should be placed in the holes, and in this the Dahlias must be planted, fastening each securely to its stick with a stout strip of matting. As the plants progress in growth, which they will do rapidly if no check is received from cold, the side growths must be thinned out, and when those that remain are grown sufficiently sticks must be put in to support them. The Dahlia grows at a very rapid rate, and in this stage it takes up a large supply of strong food. The surface of the ground should be covered with short manure, and when the dry season sets in the plants require plenty of water. It is necessary to shade the flowers if they are intended for exhibition, and a very watchful eye must be given for earwigs, which are remarkably fond of the petals. This pest must be constantly trapped, either by placing small pots inverted with a little moss in them on the top of the sticks, or some bean-stalks cut in 6-inch lengths ought to be placed about the plants; into these the insects crawl at night, and can be destroyed next day.

The following is a list of stage and fancy sorts adapted either for decorative purposes at home or for cutting for exhibition:—

*Show Dahlias*.—Aeme of Perfection, Alexander Cramond, Arbitrator, Barmad, Charles Leicester, Cremorne, Flag of Truce (Goodall), Herbert Turner, James Cooker, James Service, John Dunnington, John Standish, Julia Wyatt, Lady Gladys Herbert, Leah, Mr. Sinclair, Mrs. Boston, Mrs. Henshaw, Ovid, John Bennett, Prince Arthur, Royal Purple, Samuel Plimsoll, Thomas Goodwin, Toison d'Or, William Keynes, William Pringle Laird, Yellow Standard, and Willie Austin.

*Fancy Dahlias*.—Dolly Varden, Ebor, Egyptian Prince, Flora Wyatt, Flossie Williams, Grand Sultan, Laura Haslam, Miss Lillie Large, Mrs. Saunders, Mrs. Standish, Parrot, Pauline, Prospero, Remarkable, Rev. J. B. M. Camm, Richard Dean, and Viceroy.—J. DOUGLAS.

## FRUIT TREES FOR SMALL GARDENS.—No. 2.

THE selection of one, two, or half a dozen sorts of Pears and Apples is, I think, much more difficult than the choice of other fruits, from the fact of the great number of kinds of real excellence which we have of both these useful fruits. If I am asked to name one sort I reply to my querist by asking at what time ripe Pears are most wanted, as the period during which they may be had extends over two-thirds of the year. In August one of the best Pears is Citron des Carmes, in September Williams' Bon Chrétien, in October Comte de Lamy, in November Doyenné du Comice and Dana's Hovey, in December Winter Nellis and Knight's Monarch, which last affords a supply of ripe fruit from December to March. Dana's Hovey, from its sturdy compact growth and great fertility, is specially adapted for small gardens. Its delicious little fruit, which ripens in November, keeps good quite six weeks after it is ripe.

An Apple which ripens in autumn and keeps good for two or three months is of more general use than other sorts of more brief duration and coming to maturity very early or very late. The variety which I may therefore select as a good autumn and winter dessert fruit is Cox's Orange Pippin. Irish Peach and Kerry Pippin are the best earlier sorts, and Margil is in season with and keeps good a month longer than Orange Pippin. All four are prime sorts admirably adapted for small gardens, Margil being especially remarkable for the productiveness of young trees of it upon the Paradise stock. For a supply of kitchen Apples from August onwards through the nine following months take Keswick Codlin, Duchess of Oldenburg, Cox's Pomona, Alfriston, Hanwell Souring, and Gooseberry Apple. The great productiveness of Keswick Codlin in all stages of growth, from the smallest newly planted pyramid up to the hoary old standard, its earliness, and compact yet free growth, combine to make it an especial favourite in all gardens. All the other kinds are of the highest order of excellence in their respective seasons. I have long ago sung the praises of Hanwell Souring, which is good long after spring flowers make their appearance, and I would now strongly com-

mend Gooseberry Apple to general notice as a fine old sort of much excellence for tarts in May and June when other fruit is scarce. Its fruit keeps best when suffered to hang long upon the trees—late in October, a few frosts doing it no harm.

The very limited area of wall space in a small garden should be exclusively devoted to the Peach, Nectarine, Apricot, Fig, Cherry, and Plum; the south, or west, or intermediate aspects answering best for Peaches and Nectarines, taking the south-west for choice, the east for Apricots, and the north for late Cherries and Plums. Figs answer well in any warm tolerably sheltered sunny position. By late Cherries I, of course, mean Morellos, so useful late in autumn, and with them I would always associate the two fine late Plums Ickworth Imperatrice and the old Blue Imperatrice, both valuable October dessert fruits, keeping good long after most other sorts.

I may usefully conclude these notes with a word of advice, or rather of caution, upon the evils of crowding young trees together and overcropping. However small your garden may be, never crowd the trees or anything else; far better is it to grow a few trees really well than several more than you have room for very badly. Eschew "riders" on walls, plant dwarf-trained trees 20 feet apart, plant well, and let nothing tempt you to put other trees temporarily between them. If you do, an impoverished border, confused, crowded, often diseased growth, will follow. The removal of the interlopers will very likely be put off year by year till the whole of the trees are irretrievably ruined; and by the time you would have had the wall completely clothed with fine healthy trees in full bearing, and with every prospect of their continuing so for a lifetime, you will have a state of things leading to total failure—stunted growth, which, if not barren, bears fruit that is so small and poor-flavoured as to be comparatively worthless.

In or around the quarters of the garden plant either cone-shaped trees termed "pyramids," or those which are trained on wires or a wooden trellis, and termed "espaliers," the first kind to be 10 feet apart, and the last 20 feet. Plant no "standards," as those trees are called which have their branches elevated on long bare stems. They are unsightly objects, affording no pleasure in their culture, they shade a large portion of valuable ground, and what is, perhaps, most important, are very subject to have much of the fruit battered by the wind or shaken off prematurely.

Whatever may be the form which you may impart to your trees, keep the branches sufficiently far apart to allow light and air to penetrate freely to the base of every one of them, striving to render every part of a fruit tree available for the production of good fruit.—EDWARD LUCKHURST.

## TEA ROSES FOR A COLD VINERY.

IN answer to "H. L." First I must congratulate him on possessing such a desirable structure as a glass house 36 feet long by 18 wide. I cannot imagine anything more delightful than planting such a space with Tea Roses. As to sorts, I will give him the selection that I should plant. I apprehend that he could plant eighteen in each row, and that the space would admit of nine rows, which would therefore give him 162 Tea Roses. What a glorious privilege 160 Teas, where winter's frost will not injure, and the summer's heat is tempered to these delicate plants by a protecting but not obstructing screen of Vine leaves!

I should recommend him to have about twenty-six sorts and six of each. Of course if he has climbers he must plant them against the back wall; but if his house is a span-roofed one he must dispense with climbers.

I cannot make out what his house is; but presuming it is a lean-to one I should recommend him to plant about six climbers, which would leave a space of 6 feet to each. These should be selected from the following sorts—Cloth of Gold, Solferino, and Maréchal Niel, Noisettes; Climbing Devonensis, Madame Berard, and Belle Lyonnaise, Teas. The last-named is infinitely inferior to Gloire de Dijon: in fact this variety is surpassed by three of her children.

Next as to the remainder of the space. I should plant six of each of the following—Catherine Mermet, Marie Van Houtte, Souvenir d'Elise, Souvenir d'un Ami, Souvenir de Paul Neron, Comtesse de Nadaillac, Kubens, Homère, Reine du Portugal (this lovely variety is too tender for outdoor culture, but will do splendidly in a house), Anna Olivier, Perle de Lyon, Marie Arnaud, Jean Ducher, Perle des Jardins, Mons. Furtado, Adam, Alba Rosea, Celina Noirey, David Pradel, La Boule d'Or, Niphotos, Madame Willermoz, Madame Charles, Madame

Falcot for buds, Madame Jules Margottin, Madame Margottin, and Moiré, Teas; and Céline Forestier and Triomphe de Rennes, Noisettes. If he has not room for all he can leave out Madame Charles and Madame Falcot. If he buys these this year he should not have them sent him just now, as here the Teas are in full bloom. I should say the beginning of December would be soon enough for planting.

As to culture, he cannot do better than follow the capital advice given by one of your correspondents a little while ago in an article on pot Roses. I should, however, recommend him to prune very sparingly. He must not allow his Vines to shade the Teas too much, or they will suffer. A brother of mine who lives in Yorkshire has a span-roofed house filled with Teas, but he finds it necessary to heat it; but as "H. L." lives in Somerset no doubt this will be quite unnecessary. The sorts I have named are all beautiful varieties, as he will find about May next year.—WYLD SAVAGE.

### CRAWFORD'S EARLY PEACH.

THE gardening periodicals speak in high terms of this Peach; the couple of dishes of it exhibited this season have made a decided mark. Now, I have always held an opinion that the exhibition table is not to be compared to the dinner table for deciding the merits of anything in the fruit and vegetable line. Some may not see this, nevertheless I find it so. Few can grow Peaches merely to show once or twice in the season. Most of us are expected to have a supply of Peaches for the table daily from August to the end of September from outdoors, and if we have houses so much sooner must the fruit be ready. To do this we must have reliable varieties. To those who have room only for a tree or two it is still more important to have not only good productive sorts, but also varieties that will hold their own at the exhibition table; there are plenty of established varieties that will do both.

I give way to no one for love of variety when it is good, but I cannot allow that—I may call it a whim—to carry me away from that which is serviceable. It is all very well to have variety when room will permit, as, for instance, in large gardens let there be Crawford's Early by all means. In penning these remarks I am thinking of others having limited wall room, and who may, after what has been written of Crawford's Peach, be inclined to give it a place as a reliable variety. Well, so far as my experience goes it is far from being a reliable variety; so much so, that after three years' trial after the tree had become of a fruiting condition I find this rosy-cheeked beauty only obtain applause when before a public audience; but if we look, as it were, behind the scenes—namely, in the family circle, we find a very different estimate, for one good and beautiful Peach will hardly counterbalance the five or six ill-looking disagreeable fruit accompanying it.

I have always entertained a different notion of the words "good" and "bad" from most people. It is generally said, "Oh, give me little and good," &c., but I say, Give me plenty of what is good, and as little as possible of what is bad.

Now, it is just possible that Crawford's Peach may suit those who want little and good, for they will surely have little that is good, and as surely have much that is bad for the little that is good. Crawford's Peach is for the few and not the many. When you can obtain enough it is fine for the exhibition table, but we have plenty far better varieties for the home table—large, high-flavoured, good-looking, heavy-cropping sorts of the same season of ripening. We may find a place for this variety if it came extremely early or late, but it is neither. We have our latest Peach in the Salwey, of which Crawford's "Early" may be called a midseason variety. Taking the two the Salwey is far the best, simply because it carries us on for a few weeks after the better sorts are gone. I feel I am not the only one who thinks Crawford's is not a desirable Peach. If not so, why is it we have not heard something of it from those who have cultivated it? So far as I have read not a word has been said from them, and I may say the proper quarter. On what grounds, then, has it been spoken so highly of? Only, I presume, from the few dishes that have been seen at the exhibition table.

Let those unearth themselves who have found it to be other than what I have said of it, and give the readers of this Journal some proof that it deserves their attention as an "excellent Peach." Here is my three years' experience of it:—First year no fruit. A good few on most of other varieties. Second year a fair crop as regards number, but not one in six came to perfection—viz., one good eatable large fruit to five or

six small ill-flavoured, ill-shaped, worthless fruit. All other varieties produced a very heavy crop of large high-coloured well-flavoured fruit. The third year the tree had five or six fruit, and one of them was a perfect beauty, as noble fruit as ever I saw, and it had, too, four or five small, the size of a good Plum—as worthless fruit as a tree could produce. No one could eat them—no, not even a hungry schoolboy. It only remains for me to say that the tree is in perfect health.—JNO. TAYLOR, *Hardwicke Grange.*

### THE CULTURE OF LETTUCES.

THIS well-known and long-established vegetable is so common and cultivated in such large quantities, especially in the neighbourhood of London, that it might be termed the salad for the million, nothing being more relished as a salading by all classes of the community than a well-grown Lettuce.

Simple as the growth of Lettuces may appear, it is not by any means an easy task to keep-up an unbroken supply of well-hearted, well-blanching, and crisp Lettuces, but one which requires a considerable amount of forethought and attention. To meet this demand it is necessary to make one or more sowings of the Bath or Brown Cos (black-seeded), in an open space during the second or third week in August. I usually sow on or about the 20th, but sometimes the date has to be regulated by the weather. From these sowings sturdy plants are to be obtained during November: they must be planted under hand-lights, frames, or on the border of a south wall, where they will stand most of our ordinary winters without protection. In this border I plant them 6 inches apart, and during March prepare a rich piece of ground, when I carefully lift with a trowel or fork every other row and every other plant in the rows remaining. These I transplant a foot apart, and they form a succession to those left on the south border, which will furnish an excellent supply of crisp Lettuces in early May. Attention must be paid to frequent hoeings and waterings should a dry spring set in. This variety if grown quickly and well blanching is considered to be the most crisp and best-flavoured Lettuce grown. Should any fear exist of not having a sufficient early supply, the Early Paris Market Cabbage variety, sent out by Messrs. James Veitch & Sons a year or two since, is an admirable sort for quick produce, and may be used very young. A few seeds sown among the early frame Potatoes or Carrots, and the plants planted before they have become weak or drawn will be found to turn-in very quickly, and will prove valuable where the demand is great. It will be found a very good plan to sow a pinch of the seed of this variety on a warm border during February, as also a sowing of Paris White Cos, or the selected stocks of this variety the Kingsholm and Alexandra White Cos, which will form a good succession to the above. After this time it will become necessary to make a sowing every fortnight or three weeks, and I know of no better summer Lettuce than the Paris White Cos. It is, under good cultivation, self-folding, and has not a very hurried tendency to bolt with the heat and drought.

A plan which I generally adopt, and which I have great confidence in, is to sow on a well-manured but light piece of ground in drills a foot apart, thin-out before the plants become crowded, and transplant the sturdiest of them, which form a succession to those left remaining where sown. I am a great advocate for lifting Lettuce plants carefully, for breaking the roots and fibres causes a great check and predisposes the plants to bolt when transplanted; but Paris Cos, if sown successionally and treated as advised, will carry on a supply until frost sets in.

Two sowings of the Bath or Brown Cos should be made the middle of July to the first week in August. The former of these will give a supply of plants during October and November, and the latter will carry us on from Christmas onwards. The plants from these sowings will of course require protection under glass, so they must be lifted with good balls and planted in frames in an open position, for damp is a great enemy to them in these quarters; it will therefore be necessary to give all the air possible consistent with keeping them dry.

I have always found that the Cos varieties are most in request, but, judging from what I saw a short time ago in Plymouth market, I should say they are very little known in the west, for not a creditable specimen was to be had, but good Cabbage Lettuces were plentiful. On inquiry I was told they had no sale for the Cos varieties. All the Year Round is a first-class Cabbage variety, and worthy of being grown where the Cabbage varieties are not objected to.

In tying Lettuces for blanching the work must not be done while they are wet or when they are very hot, or they are apt to sweat, and consequently decay inside. Slugs are great enemies during autumn and winter to the Lettuces, also a grub—the larva of some insect, both of which must be waged war against. The first of these devours the tops, while the grub will be found to gnaw plants off at the junction of the stem; these grubs will be found buried in the ground.—  
J. W. MOORMAN.

| 8. Louis Van Houtte         | 33. Gloire de Dijon          |
| 9. Maréchal Niel            | 34. Horace Vernet            |
| 10. Marie Baumann           | 35. Lyonnaise                |
| 11. Madame Victor Verdier   | 36. Paul Neron               |
| 12. Baronne de Rothschild   | 37. Madame C. Wood           |
| 13. Mdlle. Eugénie Verdier  | 38. Madame Lacharme          |
| 14. Marquise de Castellane  | 39. Madame Willermoz         |
| 15. François Michelon       | 40. Madame G. Schwartz       |
| 16. Etienne Levet           | 41. Madame C. Joigneaux      |
| 17. Marie Rady              | 42. Niphotos                 |
| 18. Marguerite de St. Amand | 43. Maurice Bernardin        |
| 19. Sénateur Vaisse         | 44. Prince Camille de Rohan  |
| 20. Xavier Olibo            | 45. Pierre Notting           |
| 21. Auguste Bigotard        | 46. Reynolds Hole            |
| 22. Belle Lyonnaise         | 47. Souvenir d'un Ami        |
| 23. Beauty of Waltham       | 48. Souvenir d'Elise         |
| 24. Camille Bernardin       | 49. Souvenir de la Malmaison |
| 25. Catherine Mermet        | 50. Victor Verdier           |

Mr. BURRELL, Heighington, Darlington.

- |                          |                      |
|--------------------------|----------------------|
| 1. Charles Lefebvre      | 6. Madame V. Verdier |
| 2. Alfred Colomb         | 7. Dr. Andry         |
| 3. Baronne de Rothschild | 8. Maréchal Niel     |
| 4. La France             | 9. Louis Van Houtte  |
| 5. Marie Baumann         | 10. Etienne Levet    |

11. François Michelon
12. Pierre Notting
13. Marquise de Castellane
14. Ferdinand de Lesseps
15. Mdlle. Eugénie Verdier
16. Devoniensis
17. Duke of Edinburgh
18. Horace Vernet
19. John Hopper
20. Xavier Olibo

21. Comtesse d'Oxford
22. Exposition de Brie
23. Dupuy Jamain
24. Thomas Mills
25. Monsieur Noman
26. Emilie Hausburg
27. Annie Laxton
28. Gloire de Dijon
29. Marquise de Gibot
30. Souvenir d'Elise

31. Souvenir d'un Ami
32. Mad. Hippolyte Jamain
33. Capitaine Christy
34. Reynolds Hole
35. Cheshunt Hybrid
36. Maurice Bernardin
37. La Duchesse de Morny
38. Sénateur Vaisse
39. Marie Rady
40. Abel Grand
41. Hippolyte Jamain
42. Comtesse de Serenyi
43. Catherine Mermet
44. Duke of Wellington
45. Madame C. Wood
46. Madame Willermoz
47. Duchess of Edinburgh
48. Madame Lacharme
49. Marie Van Houtte
50. Beauty of Waltham

Mr. Burrell adds, "I have put Ferdinand de Lesseps and Exposition de Brie in the list as distinct Roses, but they are so much alike that it is difficult to distinguish any difference."

Rev. J. B. M. CAMM, Monkton Wyld, Charnmouth.

- |                            |                             |
|----------------------------|-----------------------------|
| 1. Alfred Colomb           | 26. Duke of Wellington      |
| 2. Baronne de Rothschild   | 27. Edward Morren           |
| 3. Camille Bernardin       | 28. Emilie Hausburg         |
| 4. Charles Lefebvre        | 29. Fisher Holmes           |
| 5. Dr. Andry               | 30. Général Jacqueminot     |
| 6. La France               | 31. John Hopper             |
| 7. Etienne Levet           | 32. Louis Van Houtte        |
| 8. Ferdinand de Lesseps    | 33. Marguerite de St. Amand |
| 9. Horace Vernet           | 34. Marquise de Mortemart   |
| 10. Madame Victor Verdier  | 35. Madame Vidot            |
| 11. Mdlle. Eugénie Verdier | 36. Madame C. Wood          |
| 12. Marie Baumann          | 37. Madame G. Schwartz      |
| 13. Marquise de Castellane | 38. Mdlle. Marie Finger     |
| 14. Pierre Notting         | 39. Mdlle. Marie Rady       |
| 15. Souvenir d'Elise       | 40. Mdlle. Annie Wood       |
| 16. Souvenir d'un Ami      | 41. Mdlle. Marie Cointet    |
| 17. Catherine Mermet       | 42. Maréchal Vaillant       |
| 18. Maréchal Niel          | 43. Maurice Bernardin       |
| 19. Marie Van Houtte       | 44. Monsieur Noman          |
| 20. Comtesse d'Oxford      | 45. Prince Camille de Rohan |
| 21. Abel Grand             | 46. Reynolds Hole           |
| 22. Antoine Ducher         | 47. Sénateur Vaisse         |
| 23. Beauty of Waltham      | 48. Victor Verdier          |
| 24. Duchesse de Caylus     | 49. Xavier Olibo            |
| 25. Duke of Edinburgh      | 50. Devoniensis             |

Mr. Camm adds, "In this list many Roses of undoubted excellence are omitted simply on account of the list being confined to fifty. There is nothing among H.P. Roses in my opinion to be compared to Marie Van Houtte, Catherine Mermet, Souvenir d'Elise, and Souvenir d'un Ami."

Mr. CHATEL, Cambridge.

### MIXED BORDERS.

MIXED BORDERS are especially enjoyable during October and the beginning of November when we are so fortunate as to have fine mild weather, and when Geraniums, Verbenas, and the ordinary bedding plants can only be distinguished by their leaves, and those grown solely for their beauty of foliage are beginning to look dingy. There are at present in full beauty, and likely to continue for some time if the weather permits, amongst hardy perennials some of the handsomest flowers in existence: and, not only handsome flowers but handsome plants—plants with elegant foliage and symmetrical growth, which will bear examination individually as well as collectively, and to which most indoor plants as grown by ordinary cultivators at this time of year will bear no comparison. Where cut flowers, too, are much in request the mixed borders afford an almost inexhaustible store, and many of the flowers last good a very long time.

I think one of the principal reasons why hardy perennials do not receive more favourable attention is that those who make borders of them attempt too much in one place. The principal advocates for such borders claim as their especial merit that there is always something coming into flower and something going out. The "something coming in" is very well, but the other part is not so pleasant. It is not everyone who takes delight in examining withering flower stems and seed pods, and therefore to make these borders as attractive as possible to everybody they should be arranged more according to the time of flowering of the different subjects. It may be unscientific, but gardeners have to please the many, and not the few who are learned in botanical lore.

My noble employer, when making a new garden three years ago, stipulated that little or nothing should be planted there which flowered before July; and although owing to this decision I was obliged to exclude many very beautiful plants, I now see the wisdom of this arrangement and would carry it still further. In many extensive pleasure grounds, where there is an attempt at landscape effect, and where formal beds and the ordinary bedding plants are entirely out of place, owing, perhaps, to the owner's uncontrollable passion for flowers, we often see a vulgar blot on the most beautiful scenery by the introduction of such flowers and flower beds; while suitable flowers tastefully planted would give all the requisite brightness and sweetness without jarring on the taste of the most refined and critical artist.

There is no reason why there should not be a hardy perennial garden for each of the four seasons, or even for every month in the year, where there are perhaps half a hundred acres of woodland walks and kept pleasure grounds; and it is surprising when one makes out a list what a host of beautiful hardy plants there are for every month, even through the depths of winter. Spring gardening as done in the present day is frequently an abomination. Formal beds of Daisies and Primroses are incongruous, and the plants do not look half so happy as the Primroses in the woods and lanes or the Daisies in the cottage garden. I have not a word to say against parterre gardening in the proper place; Geraniums, Verbenas, and the like do not look so well anywhere else as they do in massive formal beds, and at the time they flower there is such a predominance of lively green all around that the eye can bear a great deal of colour without pain if the colours are well arranged and the plants used are suited for the purpose.

I will now name the best of the hardy plants which are

flowering to-day (October 6th), and which are likely to continue for some time, omitting all such as have yet to flower, and they are many, as well as those which are just going out of flower, and they are more numerous still. I should be glad if those of your readers who are conversant with the subject would add to the list all the good hardy early October flowers which come under their observation. I do not want those of botanical or microscopical interest only, but such as will command attention from everybody, and of such I believe are the following:—*Achillea ptarmica* flore-pleno; *Anemone vitifolia*, *A. japonica*, and *A. japonica alba*; *Oenothera macrocarpa*, *O. riparia*; *Tritonia aurea*; *Polygonum Braunii*, *P. Sieboldii*; *Chelone Lyoni*; *Helianthus multiflorus*, *H. orgyalis*; *Colechicum* in great variety, *Crocus ditto*, *Sedum spectabile*; *Lilium speciosum*, *L. speciosum album*; *Phygelius capensis*, *Galatella cana*, *Tritoma grandis*, *Alstromeria psittacina*, *Phloxes* in variety late planted, *Chrysocoma Linosyris*; *Aster patens*, *A. longifolia variegata*, *A. tenuifolia*; *Aconitum autumnalis*, *Coreopsis lanceolata*; *Stevia mexicana*, *S. canescens*; *Plumbago Larpentæ*, *Tricyrtis hirta*, and *Violets*. The foregoing are perfectly hardy; a few others not quite so hardy and worth the trouble of sheltering in such parts of the country as they require it are herbaceous *Lobelias*, *Pentstemons* in great variety, *Fuchsias* (the best varieties of these are, I believe, as hardy as *F. Riccartoni* if treated in a similar way, and they are very beautiful outside now), and *Hydrangeas*.

In addition to these I have many half-hardy plants in mixed borders in fine bloom now, but which I hope to separate from hardy plants as soon as my stock of the latter becomes sufficiently rich. Among the half-hardy plants are *Salvia patens*, *S. splendens*; *Chrysanthemum frutescens*, *C. carinatum* in variety; *Coronilla glauca* (struck from cuttings in the spring and now 3 feet high and full of flower), *Marvel of Peru*, *Intermediate Stocks*, *Mignonette*, *Antirrhinums*, *French Marigolds*, *African ditto*, *Sweet Alyssum*, *Sanvitalia procumbens*, *Coreopsis tinctoria*, *Alonzoa Warszewiczii compacta*, *Heliotropes*, *Amaranthus atropurpureus*, and *Dahlias*, of which the following are amongst the best as good showy border flowers producing an abundance of bloom of good quality without any nursing and shading—namely, *Charles Backhouse*, brightest scarlet; *Criterion*, rosy lilac; *Andrew Dodds*, dark crimson; *James Cocker*, dark purplish crimson; *Toison d'Or*, yellow, neat habit; *Netty Buckle*, light lilac; *Flag of Truce*, white; *Lady Dunmore*, crimson and orange; *Queen Mab*, scarlet and white, very showy; *Lord Derby*, purple; *Bird of Passage*, white and rosy lilac tipped, small, but exceedingly pretty; and *Chairman*, orange.—WILLIAM TAYLOR.

### WIMBLEDON HOUSE.—No. 2.

THE RESIDENCE OF SIR HENRY W. PEEK, BART., M.P.

On page 262 the ornamental grounds and flower garden of this fine suburban residence were described, and there remain to be noticed some other departments which are under the gardener's care. As was notified in the previous article, the mansion is connected with the flower garden by an avenue of Elms. These are stately trees, and form a densely shaded walk—a shelter alike from rain and sun—and a most agreeable promenade. The mansion is commodious, but not elaborately ornate, and its situation is attractive and salubrious—attractive by the fine trees by which it is surrounded and the beautiful park-like view from its windows, and salubrious by its gravelly soil and its contiguity to the wide expanse of Wimbledon Common, which is as famed for the purity of its air as it is for the annual popular volunteer fêtes, which were opened by Her Majesty The Queen, who fired the first shot on July 2nd, 1860.

On the lawn near the mansion are some fine old Cedars of Lebanon with seats around their stems, and a noteworthy specimen of that distinct and ornamental deciduous tree—*Salisburia adiantifolia*, the Maidenhair Tree. This tree is a native of China and Japan, and is there known as the Ginkgo tree. In its native country this tree attains to a height of 100 feet, and it grows generally in a conical form, but the Wimbledon specimen is of spreading habit; it is, in fact, much broader than it is long, its height being 45 feet, while the spread of its branches is 56 feet, its stem being 8 feet in circumference at 3 feet from the ground. The *Salisburia* is an elegant tree throughout the summer months, and is distinct by its wedge-shaped deeply-lobed leaves, which in the autumn assume a bright golden hue, rendering the tree conspicuous and ornamental. It is perfectly hardy, and should be more commonly seen in pleasure grounds.

On the lawn are bold clumps of Rhododendrons and standard Portugal Laurels, several good specimens of *Biota aurea*, and near the broad walk flower beds. These beds are on grass, but are surrounded with narrow paths of white spar, and, as if to render the contrast as decisive as possible, a large number of dark-foliaged plants are employed in filling the beds. On each side of the entrance to the mansion is a grand specimen of the American Aloe. These plants cannot be less than 10 feet in height, and are in luxuriant health. They pass the winter in the orangery, a large old-fashioned structure at the end of the walk. Such buildings are now obsolete, and are useless in comparison with the light modern-built structures of the present day. Near the mansion is a conservatory, but it is also old-fashioned and much too dark for ordinary decorative plants. Only one plant in the structure deserves mention—a *Lapageria rosea*. This plant was trained up one of the supporting pillars, and had grown into a dense thick column, and carried a heavy crop of mealy bug. In order to destroy this the plant was taken down, and on replacing the growths they were found to be more numerous than was necessary, and instead of cutting them off they were taken underground, and made to furnish another part of the house. The flagstones were lifted, and the shoots of the *Lapageria* laid under them, with the tips of the shoots on the opposite side. From the shoots thus layered a wonderful growth issued. From the edge of the slabs young shoots sprang up like heads of Asparagus, and this growth has covered the end of the house and a great portion of the roof. The plant is now perfectly healthy and free from the bug, which once so sorely infested it.

Pass we now to buildings of more modern date—the splendid range of glass structures which form the northern boundary to the principal flower garden. This noble range of houses was erected by Sir Henry Peek, who employed in their construction Mr. James Gray of Chelsea. The range is about 130 feet in length by 40 feet in width. The houses are very lofty, the upright side sashes being 15 to 20 feet high, and the central dome is 50 feet in height. A wall is taken the whole length of the range from the ground to about the centre of the roof on the north side. Behind this wall were formerly sheds, but which are now converted into Orchid houses and ferneries. At the southern side of this wall are the principal houses of the range—spacious and lofty places, devoted almost wholly to plant-culture. In each house is a square central pit. Passing through the corridor, the pit of the first house is planted with Roses, principally Teas. Roses are also on the walls and roof. The next compartment is occupied mostly with Azaleas, and with Roses covering the walls. From this we pass into a stove, which is filled with Palms and other ornamental-foliaged plants; a fine stock of *Pancratium zeylanicum*, which is much prized here, *Eucharis*, &c.; the back wall being covered with *Begonia nitida*, a grand wall plant in winter and spring. The roof is covered with *Stephanotis* and *Allamandas*, and Orchids are suspended over the paths. We now come to a narrow cross corridor, which contains large plants of *Hedychium coronarium*; and amongst the wall plants is *Phytolacca decandra*, laden with pendulous racemes of its dark-coloured berries. This corridor adjoins the central compartment. In the centre under the dome is a specimen of *Araucaria excelsa*, surrounded with *Seaforthias*, *Alsophilas*, &c. At the front of these is rock-work furnished with Ferns, Lycopods, Yuccas, &c.; on the north side, a fine specimen—a centenarian—of *Beaucarnea recurvata*. At the corners or angles of this principal compartment, which is square, are beds of *Camellias* with other plants associated with them. Going westward we enter another cross corridor, occupied with *Plumbagos*, *Lapagerias*, and Olive trees from Portugal; and from this corridor we enter the aquatic house.

In the centre is a tank 25 feet square, in the warmed water of which are growing *Nymphæas* in variety, *N. dentata* being the most admired, with *Papyrus*, &c. Supported above the surface of the water are stove plants which require moisture, the large original plant of *Tabernaemontana coronaria* being particularly noticeable. It is a large standard plant having a head 4 or 5 feet in diameter, and flowers freely. From this plant Mr. Ollerhead has propagated a large number of young plants, which are also in a flowering state. The roof of this house is covered with *Allamandas*, not trained closely and formally, but the shoots are allowed to fall in natural festoons; these are literally laden with flowers, producing a canopy of gold of remarkable beauty. In this house *Allamandas* are exactly "at home," and it is no exaggeration to say that they have produced many thousands of flowers during the season.

In this house *Cattleyas* are grown on rafts and suspended from the roof; and the place and mode of culture are precisely suited to them, for they are in luxuriant health and in due time cannot fail to produce grand flowers. *Lælia superbiens* is exceptionally vigorous, and is throwing up robust flower spikes freely. We pass next into the Banana house, the central pit being occupied by these stately tropical plants. It is from this house that Mr. Ollerhead cut the remarkable cluster weighing 97 lbs. which was exhibited at South Kensington during the present season, and for which a cultural commendation was unanimously awarded. The roof of this house is partially covered with *Passifloras* and *Dipladenias*. The next and last division is filled with Orange trees from Lisbon, which are being prepared for Sir Henry Peek's new place in Devonshire. In this house are large numbers of *Adiantum farleyense* which appear to grow in common loam like weeds, and a number of succulents. A porch at the end of this division opens into the flower garden. Such is a rapid glance at this range. Many plants have necessarily remained unnoticed, such as collections of economic plants, fine *Euphorbias*, &c. It should be mentioned, however, that the back wall is clothed with Roses, &c., which are growing in the central pits, and are conveyed over the paths by a series of wire arches, which are both ornamental and useful; no provision having been made for forming a border at the foot of the wall for growing climbers.

At the back of this range, as before mentioned, is another range having a northern aspect. Of this range it can only be said that one division is filled with Pitcher-plants of all the best kinds; another division is devoted to East Indian Orchids; another to cool Orchids, *Odontoglossums*, *Maadevallias*, &c.; and other divisions to Ferns and *Camellias*. Of the plants generally it need only be said that they are in excellent health. The Orchids are numerous, and proof has been afforded at the Floral Committee meetings of the Royal Horticultural Society that these plants are in excellent hands.

Behind this range are other houses of a plainer description and devoted to the growing of fruit, also plants for cut flowers and ordinary decorative purposes. A range of the same length as that noticed is devoted to the cultivation of Vines, Peaches, and Pines. The Vines are old, and are growing in soil that appears to be a mixture of sandy loam and peat—much too light and poor in its nature for the requirements of the Vine; yet by top-dressings and copious supplies of water fairly good crops of Grapes are obtained. These unsuitable Vine borders would doubtless be renewed and fresh Vines be planted in proper soil were it not that Sir Henry's new and extensive Devonshire garden is receiving primary attention. The Peach trees in this range are exceedingly clean and healthy, and have perfected satisfactory crops of fruit. Pure water has been relied on in keeping the red spider out of these houses, and it has succeeded notwithstanding the great heat of the summer and the exceptional lightness of the soil. The Pines in this range of glass are succession plants looking well. In the pinery are collections of *Phalænopses*, *Calanthes*, *Phaiuses*, an *Amorphophallus* with a bulb nearly 2 feet in diameter, *Vanilla* overhead, and *Stephanotis* on the back wall. On the back wall of the early vinery Shaddocks are grown, and a good crop of fine fruit is now being perfected. The outside border at the front of these houses has throughout the summer been exceedingly gay with Lothian Stocks, which are amongst the finest and sweetest of all spring and summer garden flowers. The front wall of this border next the walk is covered with a close compact-growing Ivy, as also is the low wall of the grand range on the opposite side of the walk. These houses are heated by a large Trentham boiler, which is connected with more than a mile of piping and does its work effectively.

Further back and in a walled enclosure are other ranges of glass. There is a pinery 50 feet in length in two divisions, the plants in one compartment nearly all showing fine fruit, some being nearly ripe, and the winter's supply of Pine Apples is amply provided for. It is in this house where the remarkable hedge of *Euphorbia jacquiniæflora* is growing at the back of the Pines, and which will in due time produce a cart-load of brilliant sprays. On the curbs and front stages are grown table plants in most of the fashionable kinds, such as *Crotons*, &c., and a fine stock of the lovely *Caladium argyrites*. Here also is a plant in remarkable colour of the variegated Pine, *Ananassa sativa variegata*, the leaves being suffused with deep pink. In this house also are grown in large pots Cucumbers for the winter supply.

Another range of similar dimensions is devoted principally

to Melon-growing and propagating. The back wall of the propagating house is covered with *Bougainvillea glabra*, which is found to be of great value for cutting; and on the back walls of the Melon houses are trained several plants of *Plumbago rosea*. This is most beautiful when in flower, and the plants continue flowering over a long period, but unfortunately when cut the beauty of the flowers is extremely transient. The Melons are trained on trellises near the glass, the plants being planted near the front, about 18 inches apart, and each trained to the top of the house and confined to a single stem. The crop has been very large, and there are a great number of fruits still to ripen. Only two varieties are grown: Conqueror of Europe, an oval-shaped handsomely-netted white-fleshed fruit of rich flavour; and a round-fruited variety—Ollerhead's Hybrid—which is the result of a cross between the two capital varieties Golden Gem and Colston Basset. Besides being of superior quality, this variety possesses the property which Mr. Abbey suggested to be so desirable, of being a continuous cropper. The same plants have produced a supply of fruit from the earliest period of the season until the present time, and even now there are fruits of almost all sizes and swelling freely. Added to its external productiveness it is of high quality, and is unquestionably a variety of great merit and usefulness. In the front of these ranges of houses are other long, heated, brick pits for plant-growing, and which are now filled with a stock comprising *Poinsettias*, *Clerodendron fallax*, *Centropogons*, *Thysacanthuses*, *Eupatoriums*, *Goldfussias*, &c.

Fig. 47.—Ollerhead's wire-straining requisites.

Cucumbers and Melons are also grown in dung frames in the frameyard.

The kitchen garden remains to be noticed. It is less than two acres in extent, and is surrounded by brick walls. The south wall is especially noticeable by the fine crop of Peaches and Nectarines, and the clean and healthy appearance of the trees. Not a sign of red spider is to be seen. The natural antidote of red spider is considered by Mr. Ollerhead to be a vigorous growth. The trees are old and were once weakly, but they are now strong, and the fruit resembles that from young trees. This is the result of bold treatment. The soil was taken out of the border, and the roots cut off at about 4 feet from the wall; not lifting the trees, but chopping the soil down at that distance from the wall and replacing it with richer and stronger compost. Into this fresh roots penetrated, and the old trees became as it were young again. A border planted with Pears and Plums was subjected to similar treatment and with the same good results, and other borders are waiting their turns of being dealt with in the same effectual manner. The kitchen-garden crops are ample and healthy, thanks to deep trenching and manure water. Besides the crops usually found in gardens *Dioscorea Batatas* is cultivated rather extensively, the stems being trained up sticks similarly to Scarlet Runners. On one of the borders a valuable batch of Tea Roses is growing which were raised from cuttings of young shoots struck in heat in the spring—the best and quickest of all modes of raising Tea Roses, at least so says Mr. Ollerhead, and certainly his plants are in excellent condition.

On the borders are young fruit trees in different forms in course of preparation for final planting; and on the sides of the walks are fifteen hundred pots of Strawberries for forcing, the favourite varieties being Sir Joseph Paxton and Keens' Seedling.

In another garden vegetables are also grown and an extensive collection of fruit trees. On the sides of the walks are horizontal cordons, the wires for which are strained on a simple and effectual plan devised by Mr. Ollerhead. This mode of wire-straining is so good and so easy of being adopted by all who care to do so that a few particulars relating to it are herewith given.

Secure one end of a wire to a staple which is driven into a wall or post; at the opposite end, and at any required distance, drive firmly in another staple, similar to No. 3 (fig. 47), the projecting shoulders of the staples facing the line of wire. After drawing the wire as tightly as possible thread it through as many studs as are required to support it at the proper distance from the wall or ground. Next place the collar No. 1 on the bolt No. 2, and place it in the socket of No. 3, screwing on with the fingers the nut No. 4; now pass the end of the wire through the hole in the collar and bolt, and after pulling it as tightly as possible with the aid of pincers sever the wire almost close to the bolt, and just turn the end back. There is no fear of its slipping back through the hole, for the loose collar acts as a vice. Now with a screw key—holding the nut with one hand, and a spanner turning the bolt with the other—the wire can be tightened even to the breaking point, or until the staples are pulled from their places; in fact, tighten as one will, there can be no turning-back of the bolt and no slipping of the wire, for as the bolt is turned one way the loose collar binds in the opposite direction, securing the wire at any given point of tension. The loose collar also acts as a fulcrum between the head of the bolt and the shoulder of the staple. It is the loose collar which constitutes the excellence of the system. Before adopting the collar, either the bolt turned back (unscrewed) or the wire was cut at the edge of the hole, but now neither one nor the other of these drawbacks can possibly occur. The collar is made of a strip of sheet iron, and is not welded. As the little requisites are figured their full size for ordinary wire, it is plain that they can be made by any blacksmith, and the work for fixing wire in large or small quantities for any gardening purpose becomes a work of the greatest ease. The system is successfully adopted at Wimbledon, and will be carried out on a large scale in Sir Henry Peck's new Devonshire

garden, which is being formed under the direction of Mr. Marnock. Mr. Ollerhead places this system of wire-straining at the disposal of the public.

The gardens at Wimbledon House are evidently in the possession of a liberal owner (the gardener's cottage and young men's room are models of their kind), and are managed by an able gardener.—J. W.

#### EARLY APPLES.

ON page 307, in the account of early Apples, the following passage occurs:—"Can it be the fact that an Apple so excellent as Irish Peach is not in general cultivation?" It is a fact, so far as I am able to judge, that this Apple is not in general cultivation. There can be no question about the merits of the Irish Peach Apple as an early variety—in my estimation it has the pre-eminence. It is very little known in this locality; only in two instances have I seen it within the last twenty years, once as a standard in a large orchard bearing fine fruit ready for table, and as early as the White Juneating and Early Red Margaret; the other on a south wall on limestone, and producing magnificent fruit. Too much cannot be said in favour of what appears to be a neglected kind of early Apple. Our early Apples have long been in the background, and I am glad to see that they are now receiving the attention which they merit.

I trust we shall hear of other pomological societies being formed besides that of Woolhope, where ideas may be inter-

changed and the nomenclature of our fruits be corrected; for in regard to Apples we are sadly deficient in the question of names. In some parts of Yorkshire there is an early variety known as Bertle and Nicholson's Sweet Apple, probably only a local name. The fruit is in use about the end of June, and is much prized in the haytime. The tree is a free grower, attaining a good size, and is a great bearer. The fruit resembles a moderate-sized Keswick Codlin. Can any of the readers of the Journal furnish any information respecting it?—NORTH YORK.

### ROSES AT LEEK.

SEEING an article in the Journal entitled "Roses for a Small Collection," I felt tempted to send you some account of the difficulties under which we have to cultivate Roses here, and the sorts which do best. We are about 2400 feet above sea level, and have no shelter from east winds. We live, if we may infer from whence issues all the Rose lore, outside the zone of a Rose climate, and I do not remember ever seeing an article written on Roses north of us. Nothing but a deep love of the Rose, coupled with dogged perseverance, and I may modestly say a little knowledge, would enable us to succeed as satisfactorily as we do, for notwithstanding these difficulties we should no doubt surprise some of our more favoured Rose-growing friends were they to pay a visit to our show a little after the middle of July. We dare not fix our date earlier. We did once or twice and had to alter it. Some of our friends may recollect what Mr. Camm said in the Journal. Comparing the Leek with the Hereford amateurs, he said the latter "were nowhere," an opinion which was encouraging to me for one. May to us is the most dreaded month in the whole year. I do not know whether Tom Moore says anything about "the lovely month of May," but I think he does not, as he did not live far from us, and would know better; and so, indeed, would those gentlemen who write so delightfully about it if they were to spend the month of May in Leek.

I will now proceed to give you a list, in the order of merit, of those Roses which do best here, and which can be depended upon, not disappointing let the season be ever so unfavourable:—Charles Lefebvre, Baronne de Rothschild, Louis Van Houtte, Marie Baumann, Alfred Colomb, Pierre Notting, Madame Victor Verdier, Général Jacqueminot, Sénateur Vaisse, Duke of Edinburgh, Dr. Andry, Mons. Boncenne, La France, Dupuy Jamin, Madame C. Crapelet, Countess of Oxford, Maurice Bernardin, Marquise de Castellane, Etienne Levet, Prince Camille de Rohan, Reynolds Hole, Annie Wood, Marguerite Dombrain, and Felix Genero.

We have a few other varieties which occasionally give us good blooms, but they are few. Madame Lacharme has been beautiful the past summer, the only season I have been able to bloom it out of doors; Capitaine Christy has bloomed very freely, but has been flat and ragged; Monsieur François Michelin, which writers in the Journal extol so much, seems too tender here, and I have not yet seen a good bloom. Many others I could name of whose beauty we can only hear through your pages.—S. EXRE, *Leek*.

### TOMATOES AND THE POTATO DISEASE.

YOUR correspondent, A. Boyle (page 305), appears to open up quite a new question in connection with the remarks I made on diseased Tomatoes in my communication on the culture of this esculent. Although I cannot as yet fall in with your correspondent's views in their entirety, I think it a question that is open to discussion, which will ventilate an important subject.

I cannot quite call to memory the year I had numbers of Tomatoes diseased, but think it must have been either 1873 or 1874, and to the best of my recollection no Potatoes were growing near them at the time they were in fruit. The very early Potatoes may have been grown on the same border, but would have been dug long before the Tomatoes became diseased. If this disease is analogous to the Potato disease, it is probably more or less hereditary to the Solanum family. It is somewhat singular that the disease does not put in an appearance until the fruit is almost matured, so that I rather think that the Tomato was rendered liable to the disease by an excessive degree of cold and wet when they require an extra effort and more of warmth to perfect the fruit. My Tomatoes were very late the year they were diseased, which apparently is the case with your correspondent's.

I have not seen or heard of many cases of either Potato or

Tomato disease this season. I shall be glad to hear what others of the readers of the Journal think of Tomatoes "taking the true Potato disease from neighbouring Potatoes whenever there is wet weather."—J. W. MOORMAN.

### WINDOW BOXES IN WINTER.

WINDOW BOXES which have been gay during the summer with Geraniums and other tender plants are now losing much of their beauty, and it will soon be necessary to clear the plants out altogether. A good many people are in the habit of growing plants in window boxes throughout the summer, and allowing the boxes to remain empty during the winter-half of the year. But this is not a very enjoyable system of window gardening, as during the winter, when everything outside is desolate, is the very time when fresh cheerful-looking plants about the window are most appreciated. Of course, bright flowers cannot be had in any great quantity from now onwards for many months, but there are many hardy, fine-foliaged, and herbaceous plants which can be used with as much effect as any flowers.

As soon as the summer plants have decayed the box should be taken down and the whole of the contents emptied out, and after placing a few bits of any rough material in the bottom the box should be refilled with fresh material. Window plants do not generally grow much in winter, and it does not matter if the soil is not very rich. In towns where it is difficult to obtain good soil, or soil of any sort, road scrapings do very well to fill the boxes with. The common Ivy, or the finer-coloured variegated sorts, are amongst the best plants for placing around the edges of the boxes, as they are always fresh to look at, and their habit is good for drooping over the sides. As the outside is often the only part which it is desired to drape, it is a good arrangement to do it with Ivy and plant the edge facing into the room with some of the rosette-formed *Sempervivums*, such as *S. tectorum*, *S. californicum*, and such-like common yet nevertheless pretty varieties. The centre of the box should be planted with dwarf shrubs, such as little variegated *Aucubas*, *Thujas*, *Retinosporas*, or any other kind of bush that is dwarf, compact, and ornamental in growth.

In sheltered positions where frost seldom reaches, some of the more tender plants may be placed in boxes, and amongst these there are none better than the berry-bearing *Solanums* of the *capsicastrum* type. These are all plants which may be bought cheap from any market grower or nurseryman. Boxes can also be filled with flowering plants, but it is best to mix these with the evergreens. The *Hellebores* are exceedingly useful in this way; a few strong roots of them planted here and there in a box flower during November, December, and January, when there are little else in bloom. As a sweet-scented flower in spring, a few bits of *Daphne cneorum* are always much prized, as smelling so sweetly. Wallflowers may also be included amongst the same class, as they come in very well before the summer-flowering subjects are placed outside.

Bulbs should always be extensively used in filling winter window-boxes. Crocuses and Snowdrops should be planted near the edge, and Hyacinths and Tulips may be mixed in the centre. These should not be used alone, but mixed-in with the other plants. Crowding must be avoided, but a good quantity of bulbs may always be put in without doing this. The bulbs should be put in at the same time as the other plants. All they require is to be pushed in about 1 inch below the soil. Narcissi are fragrant, but they generally become too straggly to look well in boxes.—AMATEUR.

### BESTWOOD,

THE SEAT OF THE DUKE OF ST. ALBAN'S.

BESTWOOD is one of the few places of horticultural note within easy walking distance of the town of Nottingham. Everything about the place is comparatively new. The building of the mansion was commenced in 1862 and finished in 1865, so it has few historic associations, excepting that it stands on the spot where a favourite hunting lodge of Edward III. stood. The house is a substantial brick erection, and commands extensive views of the surrounding country. The pleasure grounds, which lie principally on the south-east and west sides of the house, are very tastefully laid out, and many choice Coniferae are planted in groups and dotted here and there on the lawns. Wellingtonias do well here in sheltered positions, but in exposed situations they become stunted in growth and one-sided with the wind. There are also some handsome

specimens of the *Cedrus Deodara*, which is so becoming on grass. *Cedrus atlantica* is also growing freely, and this is found to do well in every position. In some of the shrubbery beds the Pampas Grass is growing most luxuriantly, and this is the more surprising as the Pampas is generally supposed to be very partial to a moist situation, while here it is the very reverse of this, as it is growing on light sandy mounds.

The flower garden is all within sight of the principal windows. It is not extensive, but is tastefully designed and effective both in its character and the style in which it is planted. Clematises, especially *C. Jackmannii*, were exceedingly showy, and few flowering plants are more attractive in July, August, and September. There are many different kinds of climbers trained about the lower portion of the house, the beautiful variegated-leaved Ivies and the coral-berried *Cotoneasters* being very conspicuous. The conservatory, which is attached to the west wing of the mansion, is a very spacious building, being 102 feet

long and 26 feet wide, with a centre dome 40 feet high. It was erected by Messenger of Loughborough, and has only been finished about two years. Most of the plants in the interior are planted out in beds, and the best of the specimens consist of Musas of the ensete species, two enormous-sized plants, having only been turned out of their pots while quite small last year; *Dicksonias* in splendid condition, *Camellias*, *Palms* of the *Seaforthia*, *Latania*, and *Areca* sorts, *Phormiums*, *Ficuses*, *Dracanas*, &c. Most of these are planted back from the centre path, and the front along the edges is kept gay with dwarf flowering plants. The roof is well draped with ornamental climbers, the *Tacsonias*, the old *Cobea scandens variegata*, *Plumbago capensis*, *Bougainvilleas*, and *Lapagerias* being a few of the finest.

The kitchen garden and fruit houses lie in a northern direction from the mansion, and about 500 or 600 yards distant from it. They are reached by a well-kept gravel walk, which

FIG. 48.—BESTWOOD LODGE.

runs through a young plantation that is chiefly planted with Larch and Scotch Pines. There are a good many young plantations of this kind, planted both for screen and shelter. But the rabbits make sad havoc among the Scotch Pines; yet it is found they do not interfere with the Corsican variety (*P. Laricio*), and this kind is now being substituted for the Scotch. There is a front range of glass houses along the whole width of the kitchen garden. The width of the range is 16 feet, and it is divided into a number of 33-foot lengths, and the style of the roof is three-quarters span. Beginning at the west end, the first house in the range is planted with Royal George Peaches and Elruge Nectarines. The second division is also planted with the same fruits, with the addition of the Noblesse Peach. The trees are planted in the front and trained against a half-circular trellis, and there are others against the back wall. The Noblesse is found to be fine in flavour but rather uncertain of bearing good crops annually. There is a variety named Chancellor in the first house, which must not be forgotten. Mr. Edmonds, the gardener, says it is the most certain bearer he has ever seen, as it never misses a splendid crop of superb fruit. This is a Peach seldom met with, indeed I am of opinion that few know it. I find it described in Dr. Hogg's "Fruit Manual" as follows:—"Fruit large, oval, pale yellow, dark crimson next the sun. Flesh free, pale yellow, very deep red at the stone, sugary, rich, and vinous."

The borders are made with the natural soil of the locality, which is a very light sandy loam, with the addition of a little manure. There was a splendid crop on every one of the trees this season, and this is the case every year, the fruit being much above the average in size. During the time it is swelling the borders are supplied with large quantities of cow-dung water, and just after the fruit is formed the entire surface of the border is sprinkled over with a good dose of salt, which is watered into the soil, and Mr. Edmonds says he finds it to be one of the best manures that can be applied to Peaches, and the enormous size of the fruit proves his assertion to be correct.

The next division is planted as a vinery with Lady Downes's, Black Alicante, and Trebbiano. The latter is considered to be a superior late white Grape when well ripened, but it is found to take a great deal of heat to accomplish this properly. There was a fine crop in this house. The next house in the range is the centre one, and it is erected in the form of span-roofed greenhouse, running north and south, and therefore projecting from the others. It was well filled with *Geraniums*, *Liliums*, and other softwooded plants, which render the greenhouse attractive in summer. The north end of the house is a stone wall with climbers growing against it, *Heliotropes* being amongst the principal, as yielding sweetly-scented flowers nearly all the year round when planted out, and the flowers

are much valued in a cut state. *Acacia lophantha* is another plant grown as a climber, here its graceful leaves being found to form an excellent substitute for Fern fronds in the flower vases. Proceeding onwards through the greenhouse we come to an early Hamburg house. The fruit being nearly all out I can only remark on the highly promising wood for next year's crop; but more can be said of the next division, which is planted with Muscat of Alexandria. The bunches here were models in form, their average weight running from 3 lbs. to 5 lbs., and the colour of the berries was an exquisite golden amber. I have not seen finer Muscat fruit this season, the finish being exceedingly perfect in every respect. The end division is planted with Black Alicante, Lady Downe's, Mrs. Pince, and Barbarossa, all bearing excellent crops. Complaints are not unfrequently heard of Barbarossa being shy in showing fruit. It was the same here for the first two years after it was planted, but ever since it became what may be termed established it has never failed to show many more bunches than were wanted. The Alicantes in this house were particularly fine, both berries and bunches being above the average in size, and the colour and bloom very perfect.

Crossing a walk from this house there is a lean-to stove against the opposite wall. This structure is filled with a very choice and healthy lot of Ferns, fine-foliaged plants, and all other subjects generally found in a well-managed stove. As in most places of any great extent, there are ranges of forcing houses and pits on the outside of the garden wall. Pines are well grown in one of these houses, the old Queen being the variety chiefly cultivated. Cucumbers are also grown both summer and winter. Telegraph is the favourite variety at all seasons. A large quantity of small stove and other plants for the house or room decoration are also grown here. Melons are cultivated in low pits, Colston Basset being preferred before any other sort. In the reserve ground there were large quantities of plants growing for winter decoration, such as *Chrysanthemums*, *Salvias*, &c. There were also many *Solanums* planted out in a border. These are raised from seed in spring, and they bear abundance of their ornamental berries in autumn. Strawberries are forced in considerable numbers. Keen's Seedling is the variety used for supplying the earliest fruit in March, and President follows further on.

The wall which surrounds the kitchen garden is of the most substantial description, and it is well covered with finely trained fruit trees. Peaches do exceedingly well on a southern aspect; and although Royal George does best, Noblesse, Bellegarde, and Barrington always furnish good crops. Prince of Wales has been one of the best Plums this year, and in a general way Green Gage is the most certain cropper. The Purple Gage also does well here. Its flavour is similar to the green one, and on this account it is well worth growing as a dessert fruit. As in many other cases the fruit crop in general is much below the average here this season, Lord Suffield and Cox's Orange Pippin being the only varieties carrying anything like a full crop of Apples. The kitchen garden extends to some six or seven acres, and is replete with all the kinds of vegetables belonging to this department. Asparagus, Seakale, and such like are largely forced throughout the winter. There was a large quarter planted with Veitch's Autumn Giant Cauliflower; and here, as everywhere else, nothing can approach it as a Cauliflower, its fine large white heads being cut out of doors in excellent condition up to Christmas, when Snow's White Broccoli comes in. The edges of the principal walks in the kitchen garden are planted as ribbon borders, and high-class culture and good order is everywhere visible, which is alike creditable to Mr. Edmonds and his noble employer, whose taste and interest in horticulture is worthily exemplified in many ways about Bestwood.—M.

#### VALLOTA PURPUREA AS A BEDDING PLANT.

THERE are a great number of novelties which adorn the flower garden, but I am not acquainted with any equal to the *Vallota purpurea*. To appreciate this gem it must be seen planted out, and I have proved this plant to be one of decided merit and well deserving a place in every flower garden.

We had one small bed which contained twelve clumps of bulbs, and being anxious to increase the plants I took the bulbs up on the 1st of March of this year, and carefully separated each clump into three parts, making thirty-six plants, with which I planted two beds, using a composition of two parts loam, one part decayed dung, and the remaining part of leaf soil and coarse sand thoroughly mixed together. I placed

some sand round each plant, and covered the bulbs with the soil above mentioned to the depth of 2 inches, finishing with a slight covering of sand on the surface. The result has been all one could expect. The plants have been a blaze of bloom for the last six weeks, and there are now ninety spikes of perfect flowers on each bed.

The foliage is of a dark green colour and quite ornamental in itself. It dies to the surface in November, and makes its appearance again the following April. Those beds have been much admired by all who have seen them at Muckross, Co. Kerry, Ireland.—A. CAMPBELL.

#### MILTONIA CUNEATA.

THE *Miltonias* constitute a genus of handsome Orchids. The name was given in honour of Earl Fitzwilliam, who was an ardent admirer of plants of this nature. They are mostly natives of Brazil, and consequently require a warm stove tem-

Fig. 49.—*Miltonia cuneata*.

perature, especially during the season of growth. If given heat and a moist atmosphere few Orchids grow more freely or flower more profusely, and their richly coloured flowers are admirable for cutting and the furnishing of vases, &c. The plants will grow either in baskets or in pots; if in the latter it is necessary that they be potted very high—that is, the pots should be nearly filled with crocks; and the material, very fibrous peat, sphagnum, and charcoal, should be made to form a cone above the rim of the pot. The creeping stems from which the pseudobulbs grow should be pegged to the surface of the compost with small hooked pegs, and with good cultivation the plants will increase in size rapidly. If grown in baskets the plants require much the same treatment as Stanhopeas as to heat, moisture, and rest. The species vary considerably in the size and colour of their flowers, but all are attractive and worthy of culture. *M. spectabilis* is white and violet, and is, as its name implies, very showy, as also are its darker varieties *atropurpurea* and *colorata*. *M. candida* has a white lip and yellow and brown sepals, while *M. cuneata*, the wedge-lipped *Miltonia*, is yellow and purple. The plants being epiphytally grow perhaps best in baskets, and will flourish in

any plant stove where the summer temperature ranges from 60° to 90°, and the winter temperature 55° to 60°.

### SCUTELLARIA MOCINIANA.

In late summer and autumn few plants in the stove are more attractive than this, and none are of easier culture. It is an erect-stemmed herb, with deep green, lanceolate acuminate, indistinctly toothed leaves, and numerous large, erect, slightly curved, tubular flowers in terminal crowded racemes of a bright scarlet colour, with the inside of the lip yellow, and, enduring several days, is very useful for cutting and decorative purposes. The plant attains to a height of 12 to 15 inches, or rather is best kept as dwarf as possible, as, like many others, it is spoiled when its lower leaves are lost. To keep it dwarf it requires to be kept in a light position and at a moderate distance from the glass, though my plants are 3 or more feet from it.

Cuttings of the young growths—two joints and the growing point—inserted around the sides of a 4-inch pot, three or five in a pot, in early April, strike root freely in bottom heat and a close, moist, shaded atmosphere, using sandy soil. When rooted they may be inured to light and air by degrees and withdrawn from the bottom heat, removing to the stove when hardened off. When the pots are filled with roots shift into 6 or 7-inch pots if three in a pot, or if five to 8-inch pots, draining moderately but efficiently, using a compost of turfy loam three parts and one-third leaf soil, with a free admixture of silver sand. They require to be well supplied with water, with a moist but well-ventilated atmosphere, being sprinkled overhead morning and evening. After the middle of June they will do as well or better in a cold pit, kept of course at a stove temperature by early closing, and in this position they are the better if slightly shaded in the hottest part of the day in very bright hot weather. The plants may be removed to the stove early in September. Each shoot will give a terminal head of bloom, very effective as bright scarlet flowers are in artificial light.

After flowering the plants should be kept rather dry over the winter, but the dryness is to be that of an herbaceous plant, and not the dryness accorded bulbs and deciduous ligneous plants, as compared with which they require to be moist. In March the shoots may be cut down to two joints, and the plants be kept rather dry until fresh shoots are made an inch or two long, and then repotting and some disrooting must be done, removing the old soil, repotting in the same size of pot, and in June transferring to a larger pot or kept in the same, feeding with weak liquid manure. It requires no stakes, being stiff in growth, and yet in too much heat it grows leggy, and may then require stakes. The shoots should not be stopped, at least not after May, as the flowers are produced by the points of the shoots.

Of such decorative value and so easy of culture is this plant that it should be grown by everybody having a cool stove or warm greenhouse, succeeding admirably in an intermediate house.—G. A.

### GREASY COAT APPLE.

I AM inclined to think that the Apple described by "J., Lincolnshire," on page 298, and known by him as Transparent Codlin, is identical with my Greasy Coat. I believe it is as he describes, conical, and I think somewhat five-sided, but it is seven years since I saw any, so my view is rather a distant one. The principal difference between us is in the colour; I never saw it flushed, but occasionally striped with red. By the way, I have only seen it in Lincolnshire. If not known generally I can only say it ought to be. Could not "J., Lincolnshire," supply grafts at the proper season?—J. J., Lancashire.

### HORTICULTURAL CLUB.

THERE was a very full meeting of the members of the Club at their usual monthly dinner on Wednesday the 5th inst. After dinner an interesting discussion took place on the plan proposed by Mr. George F. Wilson, of adding a large number of guinea subscribers to the Royal Horticultural Society when the separation takes place between it and the Commissioners of 1851.

Bunches of Venn's Black Muscat and Standish's Ascot Citronelle were submitted to the members. The former was pronounced not to be the same as Muscat Hamburg, as has

been asserted; and the latter pronounced a most delicious Grape, especially deserving of cultivation, as it can be grown where the Black Hamburg succeeds.

Samples of Comte de Lamy, a fine but not sufficiently known October Pear, were submitted, and it, too, was pronounced worthy of more general cultivation, the tree being a most certain bearer and the fruit of delicious flavour.

Messrs. G. F. Wilson of Heatherbank, Weybridge, F. Bell of Norwich, and George Jackman of Woking, were admitted members.

### MR. PEARSON'S GERANIUMS.

In answer to "J. H." on page 298. I have not yet tried Brutus or Mulberry. Mrs. W. Brown has been too coarse in growth with me this year, but I think most of the plants were spring-struck instead of being struck in the autumn, and consequently were not well matured or pinched-back; for one great merit which properly prepared plants have over the ordinary run of bedding-out plants wintered in cold frames or hastily struck in the spring, is that the growth is so much better ripened and matured, that instead of merely making growth when first put out they immediately begin flowering, and this habit of blooming once established they seldom make coarse or rank growth afterwards. I have noticed also that many kinds of Geraniums grow less rampant year by year. The more recently a plant has been raised from seed the more likely it is to run into coarse growth. But this is a digression.

Charles Smith is a very fine crimson scarlet, and is one which I was going to mention as very promising, but I had not enough plants of it this year to bed it, and it seems to me to be almost identical with the Rev. J. F. Atkinson, just as Edward Sutton and Sir James Outram are so nearly alike that for all practical purposes they might be planted in the same bed together. I have not very much more to add about bedding plants for this year. In a trial bed of twelve sorts, planted round the outside of a large oval bed, there are some which are likely to be very good. Mrs. Huish is of the Lord Palmerston type of colour, with very large trusses and a free bloomer, a magenta crimson with a violet tinge on the petals. Lady Stanhope is somewhat of the colour of the old Trentham Rose, *alias* Lady Middleton, but deeper, with large trusses and erect growth of flower stems. This has also made a first-rate pot plant, one which I exhibited when only a year and a half old, having made a very fine exhibition plant. Lucy Bosworth, a beautiful shade of soft pink, will do better as a pot plant than in beds, where it is very good in fine weather, but will not stand rain, but it is beautiful in pots. The same may be said, too, of Lady Byron, another pink, a rather deeper shade. Sir H. Stanhope, a fiery dark crimson (somewhat like Rev. J. F. Atkinson and Charles Smith), has done very well indeed; the form of the flower and the size would quite enlist for it the sympathies of the florist. The above are all of them raised by the late Mr. Pearson, as indeed I may say, with but few exceptions, are all the best Geraniums I have now in my garden.

Many of the more recent introductions, as John Gibbons, Miss Strachan (salmon), and many others, while preserving their Nosegay type in size of trusses and profusion of flowers, have all the qualities of florist flowers in shape, size, and smoothness of pips, and possess the great advantage over the true florist type that the petals do not drop, like those of Jean Sisley and others, from hot sun. I noticed, especially one week during the very hot weather at the commencement of August, that the whole of the ground round the edge of the bed of Jean Sisley was covered with petals which had fallen from the flowers, while none hardly had fallen from the Hybrid Nosegays.

I will now conclude these remarks with again recommending Ageratum Countess of Stair as one of the best bedding plants I have yet seen, and a great improvement upon any other Ageratum; and also a Lobelia called Alpha, which I had sent to me on trial, and which has been exceedingly good. I believe it to be a cross between Little Gem and Speciosa, combining the habit of the two, making good foliage and growth as well as bloom. The colour is a bright deep blue, not so dark as Lustrous.—C. P. PEACH.

### GOLDEN CHAMPION GRAPE.

THIS finest of all Grapes has been a puzzle ever since Mr. Thomson first introduced it. I have been more fortunate than others; but this year proper precautions were not taken in

protecting the roots against rain. The consequence was, after a slight deluge the whole of the fine bunches excepting three were destroyed in a few days, the absorption of moisture being too rapid for the delicate skin of the berries. Immediately I observed the splitting I had the covering put on the border, but it was too late. It was the case of locking the stable after the steed had been stolen. I have referred to three bunches in which there was not a berry split or spotted; and although the accident alluded to occurred a month since, these bunches still hang on the Vine in fine condition, and will apparently hang as long as the bunches on the other Vines. The cause is this: I mentioned in an article some months since that I grew laterals and tied them to the old stem, having proved that these produce finer Grapes than those from spurs. It is on one of these laterals that the three bunches are now hanging, and the cause of their not being split or spotted is no doubt the abundance of leaves on this lateral exhaling the moisture as fast as it was absorbed.—OBSERVER.

### NEW BOOK.

*A Plain and Easy Account of British Fungi, with especial reference to the Esculent and Economic Species.* By M. C. COOKE, M.A., LL.D. Coloured Plates, &c. Hardwicke and Bogue, London.

This is the third edition, which tells that it is useful; and this extract from the preface epitomises its contents:—

"When it is remembered that at the present time scarcely less than four thousand species of Fungi are found to inhabit our islands, it must be conceded that a small volume like this can only pretend to serve as an introduction to more elaborate works. In one sense, however, the present volume may be regarded as ample, since it contains, as its main feature, observations on the edible and poisonous kinds, with the best advice which could be afforded for their discrimination."

The following note is of one of the most showy and highly useful of our native Fungi, but one that the ignorant avoid:—

"One would imagine from the name (*Lactarius deliciosus*) given to the reddish-orange Fungus found in almost every Fir plantation, that it would be a treasure to an epicure; and so indeed it is, if the testimony of Sir J. Smith is to be received, that "it really deserves its name, being the most delicious Mushroom known." A gentleman of our acquaintance says that whenever he finds them he considers himself possessed of the greatest treat which the fungoid world has to offer; but that, having made their virtues known to his neighbours, it is now but seldom that he has the good fortune to enjoy them."

### NOTES AND GLEANINGS.

We are informed that the seed stores, packing sheds, &c., of Mr. Dancer, market gardener and seed-grower at Fulham, were last week DESTROYED BY FIRE, and a considerable quantity of seed and Potatoes were consumed. The fire spread to the adjoining premises of Munster House and destroyed some stabling. The origin of the fire is not known.

— ONE of the finest of autumn-flowering border plants is *ANEMONE JAPONICA ALBA*. We have recently seen this plant in several gardens, and can only wonder that its number is not greatly increased. It is a plant which should be found everywhere, for its stateliness and purity render it attractive, and its hardiness and accommodating nature recommend it to all admirers of hardy border flowers. The plants continue a long time in beauty, and the flowers are extremely valuable for indoor decoration.

— MR. LOVEL, Weaverthorpe, York, writes as follows on DESTROYING WASPS' NESTS:—"When you know the wasps are all in the nest take a lighted fusee and some tobacco, place it in the nest as far down as possible, and the tobacco smoke will then suffocate the wasps. I have tried this system and found it to be very cheap and effective."

— AN extensive grower of fruits in Lincolnshire states that he was informed at the time of purchasing DOMINO APPLE ten years ago that it was "a seedling from Keswick Codlin, which it much resembles. It bears well, but is rather subject to mildew, and, like several of our best bush and pyramid trees, will soon kill itself if allowed to fruit too soon. This is a rock upon which thousands of miniature fruit trees are wrecked. I have tried the experiment of early fruiting, and have killed scores of trees. They were put into a hospital row, but, with very rare exceptions, they never recovered. Cox's Orange Pippin, the best of all dessert Apples, is very im-

patient of being transplanted; it, like Lord Burghley, is subject to canker and mildew. As a rule, the better the fruit the more liable to both. Beurré Superfin is the most difficult to move of any Pear that I know."

— IN the small but attractive conservatory of Mr. Brassey at Preston Hall we lately noticed a very fine specimen of *WISSENSIA CORYMBOSA*. This is a very distinct and ornamental conservatory plant. It belongs to the natural order of Iridaceæ, and bears terminal clusters of blue Statice-like flowers, which remain a long time in beauty. As well by the attractive colour of its flowers and their great profusion, and also the singular growth of the plant, it is worthy of notice and of culture. Mr. Brassey's plant is a well-furnished specimen 3 to 4 feet in diameter.

— FOR imparting a distinct feature in the foliage of shrubberies the SEA BUCKTHORN is a desirable low-growing deciduous tree worthy of notice. The colour of its foliage is quite dissimilar to that of any other hardy tree, and approaches the bluish tint of *Eucalyptus globulus*. The Sea Buckthorn (*Hippophae rhamnoides*) forms a bush-like tree 12 to 15 feet in height, and its slender foliage is very elegant. It is a conspicuous tree in the front belts of shrubberies. It is perfectly hardy, and grows freely in any common garden soil either on the seacoast or in the inland counties. Its singular name is derived from *hippos* a horse, and *phao* to destroy, in reference to the supposed poisonous nature of its seeds. When berries are desired both male and female plants must be planted, for the Sea Buckthorns are dioecious.

— WRITING in "The Gardener" on destroying the VINE MILDEW by a preparation discovered by Mr. Speed, Mr. W. Thomson of Clovenfords states—"I had a good opportunity when at Chatsworth recently of testing Mr. Speed's specific. Some pot Vines had borne early crops of Grapes, and were infested with mildew. I took the spray-distributor and applied a small portion of the liquid to a leaf that was covered with mildew, and it vanished in a moment. I then syringed the leaf, and came back in an hour and examined it with a glass. There was not a trace of the parasite to be seen, though its effects were visible on the leaf. I then tried another leaf, and did not wash the stuff off the leaf as before, and the result was exactly the same. During the three days I was at Chatsworth I repeated the experiment often, always with the same results; and when I left the leaves were still completely free from the parasite, and no way injured by the liquid. I certainly never saw a more successful remedy applied before, and Mr. Speed should either make the remedy known or place it within the reach of Grape-growers."

— THE extensive park surrounding Kedleston Hall, near Derby, abounds with many of the LARGEST TREES in the COUNTY. The Oaks especially are of extraordinary magnitude, and remind one very forcibly of the celebrated giants on the Duke of Portland's domains at Welbeck, and those of Earl Manvers at Thoresby. Some of them are very old and have that half-leaved rugged appearance so picturesque and venerable-looking in park scenery. Others are in the most robust health, as will be readily conceived when we state that it is computed many of them contain as much as 1100 feet of sound timber.

— ONE of the American journals says that "it has puzzled many people to decide why the dark wood so highly valued for furniture should be called ROSEWOOD. Its colour certainly does not look much like a Rose, so we must look for some other reason. Upon asking we learn that when the tree is first cut the fresh wood possesses a very strong Rose-like fragrance, hence the name. There are half a dozen or more kinds of Rosewood trees. The varieties are found in South America and in the East Indies and neighbouring islands. Sometimes the trees grow so large that planks 4 feet broad and 10 feet in length can be cut from them. These broad planks are principally used to make the tops to pianofortes. When growing in the forest the Rosewood tree is remarkable for its beauty; but such is its value in manufactures as an ornamental wood, that some of the forests where it once grew abundantly now have scarcely a single specimen. In Madras the Government has prudently had great plantations of this tree set out in order to keep up the supply." The Rosewood is *Physocalymna floribunda*, and it is entitled to the specific name from the excessive number of its red flowers, which, when fully expanded, render it a splendid object.

— IT is known that the SEWAGE WATER OF PARIS is utilised for irrigation of the plain of Gennevilliers. Apropos of assertions that have often been made, that this would seriously

injure the health of the neighbouring population, the *Bulletin Français* has lately published some interesting facts. It was in 1868 that the method was brought into operation. In 1866 the population of Gennevilliers had reached the number of 2052 inhabitants. Dividing the series of years since then into two periods, it is found that the average annual mortality in the first period was fifty-two persons; in the second, forty-six. Not a great difference, indeed, but it is sufficient to prove that when the irrigations acquired their greatest extent the mortality did not increase, but rather diminished. Since 1872 there had been in the commune twenty-seven cases of intermittent fever, but all without exception have been in the neighbourhood of a lake into which the waters of the village flow, and on its north side. They are probably due to this lake, not to the irrigations. Again, when the sewage irrigation commenced, the hamlet of Gressillons, which is in the middle of the irrigated land, had fewer than forty inhabitants; it now numbers 327, and its sanitary state is excellent; there has not been a single case of intermittent fever. It may be added that the workmen employed in the irrigation live in the heart of this supposed centre of infection. There are thirty-five of them, and some have worked for eight years there, yet they all enjoy excellent health. The water of wells sunk in the plain of Gennevilliers is perfectly clear and limpid, though it is certain that it comes from infiltration of liquid which has not been absorbed by the plants or by the soil. This water, treated with permanganate of potash, has not been found to contain any organic matters.—(*World of Science*.)

### EXHIBITING POTATOES.

I AM not a disappointed exhibitor, as I did not compete in the classes at the Alexandra Palace Show; I have therefore the less hesitation in noticing the way in which many of the Potatoes were staged and the manner in which they were judged.

I went to the Show for the purpose of gathering information, such as would enable me on some future occasion to stage collections to the best advantage. I wished to know whether I should select tubers large or of medium size; also whether they should be simply washed, or whether they should be polished and buttered for the Judges' inspection. I went at some cost and distance, and I went hopefully, but I have returned perplexed and disappointed.

To begin with the dressing of the tubers. I am inclined to think that the Scotch polish found favour in the eyes of the Judges, and that had it not been for the gloss—the varnishing and burnishing which the tubers had received in the premier-prize collection, that they would not have won their position. I think so for this reason: By far the majority of on-lookers—and most of these competent gardeners—on being appealed to as to which collection was most suitable for the dinner table, considered that the medium-sized tubers of Mr. Pink were preferable to the large produce from Mr. Porter. On the score of appearance, however, the Scottish collection undoubtedly bore the palm.

Now there is as much difference between Potatoes which have been prepared by Scotch polish and others which have been simply washed, as there is between a pair of boots which have been oiled and another pair "shined" with the best "Day and Martin." I made several inquiries as to the mode adopted in polishing Potatoes. "Oh! it's the soil they are grown in," says one—he was a canny Scotchman. But others were less reticent, and from one who had assisted in polishing I gathered that the tubers after being well washed were smartly rubbed with a coarse cloth, are then doctored with new milk, and are again smoothed with the hand or some soft material. My informant also said that occasionally butter was used, but he regarded new milk as the best "Potato polish." Certain it is that many of the prize tubers had been operated upon with something besides pure water, and I can further say that after trying the recipe above given it produced the same appearance on the Potatoes as that borne by so many of the tubers at the Exhibition in question.

In thus polishing their produce the exhibitors infringed no rules, the only stipulation was that the tubers must be washed, and the polishers have the justification that the Judges in most instances awarded them the prizes. How far the practice is worthy of encouragement is another question. If it is legitimate to impart an artificial gloss by the application of a substance foreign to the nature of the Potato, is it not equally permissible to "dress" a flower, or add a tint to an Apple or Pear?

A short time ago I read that a fine collection of quilled Asters was disqualified because they had been dressed with flour, and I further read the opinion of a good authority that dressing of flowers is permissible by removing from them anything which marred their beauty, but to add anything to them is culpable and should not be tolerated by judges.

In the latest fashion of dressing Potatoes for exhibition it is clear that something is added to them, and that the "gloss" which "catches the eye" is produced artificially. Observe, I do not find fault with the Judges, and I am perfectly satisfied that their awards fell where they did, simply because no rule was infringed; but in future I cannot help thinking that for the sake of simplicity and uniformity it would be well that the tubers should simply be washed, and that no grease or polish should be added to them. Intending exhibitors would then know what to do; but at present they do not know how far polishing may extend, or whether suddenly and without notice it may be discountenanced by the Judges.

I should like to hear the opinions of some of the gentlemen who acted as Judges at the late Show, whether doctoring of the tubers should be prohibited or permitted.

Next, as to size of tubers. It is clear that a standard is necessary, for some judges award the palm to Potatoes which are beyond all doubt too large for any gentleman's table, while other judges allow correct table size to weigh considerably in their deliberations. It was impossible to gather from the awards at the Alexandra Show whether large or medium-sized tubers should be selected, because the Judges in some classes awarded the prizes to large, and others to comparatively small tubers. That much depends on the individual fancy of a judge is certain from the fact that the same exhibitor must stage—say, for the best dish of a given variety, one dish of large, another of medium size, and another of comparatively small tubers to "make sure of a place." Surely such a mode of guesswork is not satisfactory, and it cannot be regarded as impossible that those who give special attention to the showing and judging of Potatoes cannot make some definite provision that Potatoes to win must be of presentable size for placing on a well-furnished dinner table.

At present the standard of size is not in any way defined, and the awards at the great Show have only added to the general perplexity on this point. If the Judges were gentlemen's gardeners they must have known that they could not have placed many of the dishes which found favour in their eyes on their employers' tables. The question of size may be a difficult point to determine, but surely a man who has been sending Potatoes to table for, it may be, a quarter of a century, knows that a tuber which is large enough to fill a plate is not such as will do credit to his choice in the estimation of the guests at the table.

Unless Potatoes fulfil the conditions for which they are primarily cultivated they cannot, I think, be considered perfect. Prizes should only be awarded to perfect dishes, and we look to Potato exhibitions and judges to show us the standards of perfection, but hitherto we have looked in vain. Since the two great shows at the Alexandra Palace growers are more perplexed than ever; they do not know what sizes to select, and how far dressing is a virtue or a bane. These are questions worthy of consideration and discussion which may tend to assist both judges and exhibitors, and enlighten many.—A PUZZLED VISITOR.

### NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.—See to the planting-out of Cabbages for spring use as fast as plants can be obtained, because the weather at present is so favourable for them to establish themselves. This is such a useful vegetable that it can hardly be planted out at the wrong time, and if plants are planted on good ground where they grow quickly they can be used in quite a young state; therefore the plants may be put out thickly now, say a foot apart in the rows, and this will allow of every other plant being taken out for winter use, leaving the rest to heart in the spring. Something depends upon the sorts used. If a large-growing sort is grown the plants must not be planted so closely together, but just so that they will be finally left at a regular distance sufficient to produce good-sized Cabbages. Those left in the seed bed and which are not wanted for filling-up during winter may be planted out in spring, and will be certain to be useful.

Lettuces must be planted out under walls and sheltered places as space can be provided, and another small bed of seed should be sown. The plants from this sowing may not all thrive, but when we consider that in the autumn and sometimes the early

part of the winter the weather is mild, there is a chance of saving some to make up for any deficiency in previous crops. Onions for pulling small should be thinned a little, but not so much as they are for summer growth: all that is expected being to procure sufficient for use in salads. Preparations must be made for storing all salad crops which are advanced in growth, for the mild weather will make the plants so tender that a sudden frost will cause them to decay; a dry and airy place will suit them well if they are taken up with a little earth to their roots and if they are not in any way injured by removal.

**FRUIT GARDEN.**—Let the ground where fruit trees are to be planted this autumn be drained and trenched, and if necessary have some fresh soil added; then the trees can be planted early, which is much better than deferring their planting till a later period. By planting early the roots can make a little progress this autumn, and the trees do the better for it during next summer. Root-pruning may be commenced very soon on all over-luxuriant or unfruitful trees; they will then make fresh roots to enable them to pass through the winter safely. New plantations of Currants and Gooseberries may be made, as well as Raspberries, as soon as ground can be made ready for them. This should be deeply trenched and well manured; Gooseberries and Raspberries require more manure than Currants to grow them fine. Gather and store all kinds of fruit as the weather will allow, and do it carefully, for though it is at all times necessary for fruit of fine quality to be gently handled, this year it is particularly so on account of its being scarce.

**FLOWER GARDEN.**—Beds and borders will now need frequent attention to keep them neat and clean, and a watch must be kept for all plants that turn yellow so that their stems may be cut down, marking the places so that the roots may be found when wanted. Hollyhocks must be cut down to within a few inches of the ground, and if strong and more are wanted the stools may be parted. They must be taken up and the earth carefully shaken from their roots, and the plants cut-up with as little mutilation as possible into as many pieces as are safe to grow. There must be a good heart to each, and all be planted in a store bed to attain strength before finally planting them where they are to flower, and if there are any young shoots cuttings may be now made of them and rooted one in a pot in gentle heat.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

Owing to the mild weather and recent rains weeds are growing apace. We have been digging vacant ground, and where the weeds were small turning them down underneath the surface. We have not yet lifted the crops of Carrots, Beet, Parsnips, &c., the weather being as yet so mild that nearly all crops are in full growth. The night temperature ranges about 50°, rising above 70° occasionally in the daytime. When frosts set in the roots will be stored during fine days. A good plan is to place a layer of roots and sand alternately in a cool shed, where the roots will keep well and are easily obtained in severe weather. All roots must be lifted with care, for if they are bruised or broken decay speedily begins. Some workmen are very careless in taking up roots, and are not careful to cut the leaves off just at the right place. They ought to be cut off close to the hard substance at the crown, but not into it.

In ordinary seasons now would be the time to lift and store Potatoes for winter use, but the haulm made a second growth after the drought; and even before the rains came long root-like growths were thrown out from the tubers, at the ends of which the second lot of roots were formed. This root-action was increased tenfold after the rains, and the haulm grew amazingly. This second lot of tubers are about the stage that the usual crop would have been in July or August, and the skin peels off as it would from young unripe Potatoes. It is a question whether such Potatoes would do for planting. Some persons who have had experience say they are good for the purpose, our own experience is against them. A celebrated writer on this very subject nearly fifty years ago advocates using unripe tubers for seed, as Potatoes allowed to become fully ripe are, he says, more subject to the disease called the curl, which is often very detrimental to the crops. Potatoes intended to keep late should also be lifted with much care, as each bruise will show a black mark when the Potatoes are used in the spring. The usual, and perhaps it is the best way to keep them through the winter, is to put them into a pit, or "clamp," as it is called in Essex. A shallow level basin is dug out of the ground, the Potatoes are carefully placed in it, and they are piled-up in the form of a cone or ridge; a quantity of dry clean straw is then laid over them, and above all a thickish coating of dry earth. It is best to put the tubers away in a dry state.

It is time to see that some of the earliest heads of Endive are blanched. This may be done by bringing all the outer leaves together over the centre of the plants and fastening them with a strip of matting. We have also used slates, simply placing

them flat down upon the plants. If any weeds grow up amongst the plants it is best to pull them out by hand, as the leaves of Endive spread so closely over the surface of the ground: and even with the Dutch hoe, unless the workman is very careful, particles of soil are introduced into the hearts of the plants. We have found strong plants of Lettuce put out in frames at this season come in very useful through the winter. The frames were placed on a south border and some fine soil put in, in which to plant the Lettuce. The plants were carefully lifted and had a good supply of fresh air, the lights being drawn off when the weather was fine.

### MELONS AND CUCUMBERS.

It is very good weather still for late Melons. The heat is easily kept up in houses, and there is sufficient warmth, even when the sun does not shine brightly, to allow plenty of ventilation by day when the fruit is ripening. The ventilators should be open a little, and other instructions be attended to as advised two weeks ago. We have seen cases of disease amongst Melons this year which might perhaps be accounted for by some peculiarity of the season. The excessive heat which set in all at once in July after a dull cold period seemed to have an unfavourable effect both on Melons and Cucumbers. Sudden changes tell upon the constitution of plants as well as on the human frame; and those who have charge of glass houses, especially those intended for forcing fruits, must be ever on the alert to, as far as they possibly can, mitigate the effects of sudden changes. When very hot weather has set in after a dull period we have syringed the glass with whiting and water, and thrown open all the ventilators, at the same time keeping up a good supply of atmospheric moisture. Then the houses ought not to be shut up so early nor so close. It is a rule with some gardeners to close the ventilators at certain hours, and this is often done without due regard to the state of the weather.

After thoroughly cleaning the woodwork and glass of the Cucumber house, and limewashing the walls, the plants have been put out in good soil, but not too rich. We would rather surface-dress the plants with rich dressings than overdo the soil with manure at planting-out time. Cucumbers require more heat than Melons. A low night temperature predisposes Cucumbers to disease; indeed, a celebrated grower told us the other day that he has held the terrible disease in check by simply keeping up a high temperature and forcing the plants to grow out of the malady. The disease was not destroyed, because as soon as the temperature was allowed to fall the gummy matter began to ooze out from the stems.

### ORCHARD HOUSE.

This has given us employment during the last week, carrying all the pot trees out of doors and taking the Chrysanthemums inside. This is a work of no little difficulty, as the house is roomy and lofty and the plants large in proportion. The fruit trees will have their pots plunged out of doors in fresh cocoanut fibre. This is the best material for plunging all sorts of hardy plants and trees which are exposed to the action of frost during the winter months. We plunge the trees to the rim of the pots at present, as they will probably require water for a few weeks yet. When the frost sets in a few inches of fibre will be placed over the pots, and they will thus be secured from injury until removed into the house early in January. At that time the roots will be found in an active state and ramifying abundantly into the fresh material.

### GREENHOUSE AND CONSERVATORY.

We do not care to have any hardwood plants out of doors after this time, but the weather is so exceptionally mild that the plants are much better outside than under glass. However, there are no plants out now but Azaleas amongst flowering plants. These are always left out until the last, as we require them to flower as late as possible in the year. They are kept out to retard them, and no more artificial heat is applied than is absolutely necessary during winter when they are in the greenhouse. Red spider and thrips are equally destructive to Azaleas. If the thrips attack the plants during winter it is best to destroy the insects by fumigating with tobacco smoke. In the summer and autumn, when the plants can be syringed daily, these troublesome pests cannot do much injury. Some of the Boronias, Pimeleas, Statice, &c., if not carefully watched are sometimes irretrievably injured from the same cause. Plants may sometimes be seen with their leaves dropping off, while the puzzled cultivator wonders what can be the matter. Pimelea spectabilis is one of the most beautiful of the species, and it is worthy of being placed in the most select collection of greenhouse plants. At one time it was very popular as an exhibition plant, now it is seldom seen, though it is as easy of cultivation as any other plant. The fact is red spider is its desperate enemy, and in hot weather the plant must be syringed daily to destroy the insects. Statice Holfordii and S. profusa are distinct and most valuable plants for decorative purposes and also for exhibition. The last-named sort is the most free-flowering greenhouse plant we have, and may be had in flower all the year round; but if thrips are in the house they will surely find

it out. They lodge on the under side of the leaves, and do much mischief before they are observed sometimes. Fumigating the house two or three times at intervals of a few days is much the best way to eradicate them. Mildew is very prevalent amongst Heaths, Hedearomas, and many other plants, and it spreads at a very rapid rate when the plants are at a distance from the glass, or if the houses are not sufficiently ventilated. When the parasite has spread to a great extent over the plants, dusting with dry flowers of sulphur is not so effectual as mixing the sulphur in soft-soapy water, laying the plants on their sides and thoroughly syringing them. Perpetual Carnations have been removed from out of doors into the house. If the plants are left out much later than this the flower buds are injured and the flowers do not open well. The shoots snap off very easily; it is therefore necessary to carefully fasten them to sticks as they advance in growth.—J. DOUGLAS.

### TRADE CATALOGUES RECEIVED.

Hoopes Bros. & Thomas, Cherry Hill Nurseries, West Chester, Pa. U.S.A.—*Trade List of Ferns, Orchids, Miscellaneous Plants, Fruit Trees, &c.*

Joseph Schwartz, Rue du Repos, 43, à la Guillotière, Lyon, France.—*General Catalogue of Roses.*

T. Elcombe (late Elcombe Brothers), Spring Bridge, Ealing.—*Catalogue of Dutch and other Flower Roots.*

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LIVERPOOL (Chrysanthemums). November 2nd. Mr. R. Wilson Ker, 6, Basnett Street, Church Street, Hon. Sec.

JERSEY (St. Helier's) (Chrysanthemums). November 8th. Col. H. Howell, Hon. Sec.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

ERIXTON HILL (Chrysanthemums). November 17th and 18th. Mr. G. Gold-  
sich, Sec.

ISLE OF THANET. August 30th, 1877. Mr. C. D. Smith, Hon. Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (J. S.).—Newton's "The Landscape Gardener," published by Messrs. Hardwicke.

ELECTION OF ROSES.—It was Mr. G. Paul, not Mr. W. Paul, who was intended at page 300.

CABBAGE PALM (T. G.).—There are ten species, and two of them are natives of the West Indies, *Arca oleracea* and *A. exilis*. The first-named is that which produces edible tops.

TULIP-GROWERS.—Mr. J. McMillin asks for their names, and catalogues of their Tulips.

ANEMONE (W. B. L.).—Honorine Jobert is only a complimentary name, bestowed to please the raiser's friend. We shall like to see your notes on annals.

SEEDLING APPLE (J. W. Wooler).—It is a good Apple, but not of remarkable merit; perhaps it may improve by keeping.

ROSE LOSING ITS BARK (Hampshire).—The probable cause is want of manure and water. The tree is *Acer platanoides*, Plane-like Maple.

LIST OF PEARS AND APPLES (Mrs. Owen Knox).—Pears—baking: Catillac, Dessert: Winter Nellie. Apples: Early Harvest, Irish Peach, Kerry Pippin, Orange Pippin, Scarlet Nonpareil, Court Pendu Plat, Mannington Pearmain, Golden Reinette, Margil, Lodgemore Nonpareil, Wellington, and Cox's Pomona. The two last named are kitchen Apples.

LIST OF DAHLIAS (Novice).—White: Mrs. Henshaw. Blush: Mrs. Eckford. Primrose: King of Primroses. Orange or Golden Yellow: Toison d'Or. Lilac: Mrs. Boston. Crimson: James Service. Purple: James Cocker. Puce: Ovid. Maroon: Thomas Goodwin. Black: High Sheriff. Red: Bob Ridley. Scarlet: Charles Backhouse.

SELECT CONIFERS FOR A TWO-ACRE PINETUM (A Constant Reader).—Of the Piceas take *lasiocarpa*, *Pinusapo*, *cephalonica*, *nobilis*, *Nordmanniana*, *peccinata*, *grandis*, and *amarilis*. *P. Webbiana* may answer in such a favourable situation as yours, and it is certainly worthy of a trial. We have several thriving young trees of it which we raised from seed brought from the Himalayas. Of Pines, take *Pinus austriaca*, *Laricio*, *pyrenaica*, *Benthamiana*, *insignis*, *macrocarpa*, *Cembra*, *ponderosa*, and *excelsa*. These are all distinct in appearance and form noble trees. *Cembra* is perhaps the most insignificant of them as a small tree, but it becomes most attractive and ornamental with age. If you can spare room for *sylvestris* it will prove quite worthy of it, for although so much planted in woods and belts, individual specimens are by no means so common as they should be. Next comes *Abies Douglasii*,

*canadensis*, *alba*, *excelsa*, and *Mertensiana*, with *Cedrus Libani*, *Deodara*, and *atlantica*; *Arancaria imbricata*; *Cupressus macrocarpa*, *C. sempervirens*, *C. Lawsoniana*, with its varieties *viridis* and *gracilis*; *Juniperus virginiana*, *J. chinensis* and *argentea variegata*, *J. thurifera*, *J. verna*, also the two striking varieties of *virginiana*, *glauca* and *pendula*. The other kinds of the highest excellence are *Wellingtonia gigantea*, *Thuja Lobbi*, *Thujaopsis borealis* and *T. dolabrata*, *Libocedrus decurrens*, *Taxodium distichum*, *Salisburia adiantifolia*, *Betula pumila* and *B. pumila*, *Arctostaphylos selaginoides*, *Biota japonica*, and *B. orientalis pyramidalis*. Should you wish to form clumps or mixed groups of comparatively dwarf kinds, take *Biota (Thuja) anrea*, *B. elegantissima*, *Taxus adpressa*, *Retinospora ericoides*, *B. leptoclada*, *B. obtusana*, *R. squarrosa*, *Thuja ericoides*, *Podocarpus Andina*, *P. Koraiana*, *Juniperus tamariscifolia*, *J. oblonga*, *J. oblonga pendula*, and *J. japonica*, *Biota compacta*, and *Abies Clanbrasiliana*.

TROPEOLITUM BULBS (A Lady Subscriber).—Pot them at once as they are starting to grow, and water sparingly until the soil is well filled with roots. The plant is Borage.

MANAGEMENT OF VINE BORDER (J. C. B.).—If, as you suggest, the border is imperfectly drained and the soil has become sodden, this would account for the deterioration of the Grapes. The surface should be forked up now, and should be in a rough state until frost sets in, when a dressing of dryish manure should be applied. This ought to remain until April, when the rough portion should be removed and the remainder be dug-in. When very dry weather sets in water the border and again dress with manure.

STOVE FOR GREENHOUSE (A. S. B.).—Write to the maker you mention, and ask him to send the drawings. If the stove has a flue to carry off the smoke into the outer air it would answer your purpose.

LATE MELONS (N. N.).—Fruits which were as large as walnuts ten days ago will now have increased considerably in size, unless, as we expect, a majority of the light upon the plant have shrivelled. Thin them, if not already done, to three or four, and by keeping the temperature at 65° at night and 70° to 75° by day the fruit will ripen in November. We should fill up the house with fresh plants of Cucumbers.

CLIMBERS FOR EXPOSED SITUATION (Janthe).—There is no evergreen climber except Ivy that will succeed in an exposed position, and the most likely sort is the Irish (*Hedera Helix canariensis*). *Cotoneaster microphylla* and *Crataegus pyracantha* are the most likely to succeed of evergreen plants suitable for covering trellises. As deciduous plants, *Jasminum nudiflorum* and *Clematis montana major* would be suitable.

RAISING MANETTI STOCKS (Leo).—In November or December cut the firm wood of the current year's shoots into lengths of 10 to 12 inches, the bottom of the shoots or cuttings to be cut transversely below a bud, and the top just above a bud, removing all the eyes but the two uppermost. The cuttings should then be planted, forming a ridge about 8 inches high, and in the centre of this the cuttings are to be put in by taking out a notch longitudinally of the ridge, and into this the cuttings are to be placed, leaving one eye only above ground, firmly pressing the soil about the cuttings. They may be put in 6 inches apart, and 2 feet from row to row. In budding the ridge must be levelled so as to expose the main stems of the cutting, and in this, about 6 inches from the bottom, the buds must be inserted, and as soon after the stem is uncovered as practicable.

STOVE FOR HEATING GREENHOUSE (Idem).—We have no experience of a vapouring stove, but it is likely that stoves having no funnel will prove injurious to the plants.

CRATEGUS ORIENTALIS (R. E. M.).—The "haws" of this are very ornamental from their large size and bright colour; but we are not aware that they are used for any kind of confection. We are not aware that they are sold in Covent Garden Market.

PLANTING FORGET-ME-NOTS (Idem).—The seedlings should have been pricked off so soon as they were large enough to handle. As this has been neglected we should plant them out in their blooming quarters, having some in reserve in a sheltered situation to fill up any blanks that may occur during winter from the weak condition of the plants.

WINTERING ECHEVERIAS (Flora).—If the shed be light and safe from frost the plants may be placed in sand moderately moist, and the plants will winter safely, but the moisture and heat must not be such as to cause growth.

LAWN PATCHY (Idem).—Apply salt broadcast, at the rate of ten bushels per acre. The fungus will disappear for a time, but its recurrence may be anticipated. Some soils are peculiarly favourable to fungoid growths, especially in a dry season, a consequence probably of the presence in the soil of decomposing vegetable substances.

PROPAGATING TREE CARNATIONS (W. H.).—Select cuttings of the young shoots with two joints and the growing point, cut transversely below the lowest joint, removing the leaves from the joint, and insert the cuttings in fibrous loam with a third of sand added, placing them in a gentle heat as that of a hotbed, keeping moist and shaded from bright sun. They strike readily at any season. Tuberous-rooted Begonias should not be cut down until the leaves and stems turn yellow. Any light sandy soil is suitable for Rose cuttings in the open ground. If too heavy sand may be added, but loam that is neither light nor heavy will answer. A barren Camellia should not be cut down, but be encouraged to grow. To cut it would only still longer retard its flowering.

PHYTOLACCA DECANDRA (Irish Subscriber).—The readiest mode of increase is by seeds sown in spring in light sandy soil, placing the pots in a hotbed, pricking off the seedlings when large enough to handle, and planting out after being well hardened off in May. We do not know that the berries are suitable food for pheasants, our experience being that pheasants are not nearly so fond of berries of any kind as is often represented. They are fonder of roots—Jerusalem Artichoke and the tops of Cabbageworts—than berries, but seeds are their principal diet, varied with insects of various kinds. Pigeons eat the berries, and it is said that the flesh from the birds feeding upon them is purgative.

REPORTING BEGONIAS (H. S.).—We should not report the plants which are now ceasing flowering until signs of fresh growth are apparent in the spring. Water them moderately during the winter, giving just sufficient moisture to keep the foliage from flagging; or if they are tuberous-rooted sorts, and die down, just keep the soil from becoming dust-dry.

TUBEROUS-ROOTED BEGONIAS (D. D.).—Gradually reduce water as your plants assume their autumnal tints, withholding it almost entirely when the stems have died down. After that let the pots remain in the greenhouse until your hotbed and frame is ready, and in that frame start the tubers into growth, subsequently removing the plants into the lower temperature of a

close unheated frame or greenhouse. A heated stove is not necessary for these plants during the summer. With your conveniences you may grow the plants admirably by following the instructions given on page 301.

**PLANTING GLOBE ARTICHOKE AND ASPARAGUS (E. R.).**—The best time for planting is after the crowns have made an inch of growth in the spring, taking care that the roots are not dried during removal. Seakale roots may be planted immediately the crowns are showing signs of growth.

**NEW ZEALAND (R. Morgan).**—We never give advice as to emigration. Write to the Emigration Commissioners, and ask them to send you one of their guide books.

**VINES AND PEACH TREES IN GREENHOUSE (A Constant Reader).**—You ask, Is it advisable to grow Peach trees in a greenhouse with Vines? We say, Certainly not. By trying to do too much you are likely to do nothing well; but, if you do not determine to have them, the best sort to plant is Royal George. The best black Grape for the greenhouse is Black Hamburgh, and the best white Grape Buckland Sweetwater. The best way to warm your house would be by fixing a small saddle boiler, and if you want merely to keep out the frost three rows of 4-inch pipes would be sufficient. We should plant the Vines outside, and train the stem through the wall near the surface of the ground.

**HARDINESS OF BEGONIAS (A Subscriber).**—Provided you can keep them safe from frost, and can start them in a hotbed in spring, having them strong by the early part of June, and then planting them out in a sheltered yet sunny position, all the kinds you name will succeed; but unless you can command those appliances none will thrive except *B. Veitchii*, which is very nearly if not quite hardy.

**ROSE STOCKS FOR BUDDING.**—"Awee" says, that some time last autumn a correspondent wrote respecting Briar slips or cuttings as stocks for Roses, and asks him to give the account of his experience of this past season respecting them, and if they were planted as slips with the heel to them, and other particulars as to time of planting, &c.

**GERANIUM ROOTS GRUB-EATEN (J. W. M.).**—Grubs in the soil will eat the roots and lower part of the stems below the surface. A little lime stirred into the soil around the plants would protect them.

**KEMPTON EARLY POTATO.**—"E. K." wishes to know its origin, and if it has any synonyms.

**ASPARAGUS BED MANURING (Wimbledon Target).**—Put on some thoroughly decayed stable dung, and cover it thinly with earth as soon as the stems have been cut down. The leaf is of *Centaurea candidissima*.

**GLASS SHUTTERS (Mrs. M.).**—Apply to Mr. James Gray, 30, Danvers Street, Paulton Square, London.

**PINE APPLE BLACK-CENTRED (P. L. Bushbury).**—It arises from defective culture in some way, often from too much moisture, and especially if water is applied over the crown.

**TRANSPLANTING AN OLD VINE (Novice).**—You give no particulars as to the age or size of the Vine. As soon as the leaves fall is a good time for transplanting, securing as many of the roots as possible, and surrounding them with light soil, covering the surface of the ground with manure to prevent the frost penetrating. It will be necessary to prune the Vine much closer than if it was not transplanted.

**WIREFORMS IN VINE BORDER (Old Subscriber).**—We have not found them do any harm to the Vines; but you can destroy them, as they are no good, by placing potatoes a few inches below the surface, and examining them occasionally, when the wireworms can be destroyed.

**NAMES OF FRUITS (A. C.).**—The Grape is not Golden Champion. It appears to be a badly-coloured Black Hamburgh, but it is not possible to name a Grape correctly without seeing a perfect branch and leaves. (Mrs. Shuttleworth).—Sops in Wine. (Knutsford).—1, Sweeny Nonpareil; 2, Down-ton Pippin. (A Constant Reader).—6, Baurre Hardy; 43, Glon Moreau; 92, Van Mons Léon Leclerc. (C. T. H.).—1, Hawthornden; 2, Ravelston Pippin. (Devon).—1, Claygate Pearmain; 2, Christie's Pippin; 3, Carol's Seedling; 4, Downton Pippin; 5, Duchess of Oldenburg; 6, Nelson Codlin. (Rev. T. W. H.).—1, Christie's Pippin; 2, A cider Apple; 3, Striped Beafing; 4, Mère de Menage; 5, Morning Pippin; 6, Maiden's Blush. (C. H.).—1, Flemish Beauty; 2, Knight's Monarch; 3, Doyenné Gris; 4, Fondante d'Au-tonne; 5, White Doyenné; 6, Urbaniste.

**NAMES OF PLANTS (A. Boyle).**—*Datura arborea*. (Subscriber).—*Euphorbia Cyparissias*. (P. B.).—Specimen insufficient. (W. T.).—1, *Adiantum hispidum*; 2, no flowers (a Grass); 3, *Selaginella Braunii*; 4, *Adiantum macrophyllum*. (J. S.).—1, *Pteris cretica*; 2, cristate form of *Filix-femina*; 3, *Lastrea dilatata*; 4 and 5, *Filix-femina*; 6, *Aspidium falcatum*. (A. W. B.).—1, *Aspidium falcatum*; 2, *Aspidium aculeatum*; 3, *Lomaria spicata*; 4, *Polypodium pustulatum*; 5, *Asplenium Fabranum*; 6, *Gymnogramma L'Hermi-nieri*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### TONBRIDGE WELLS POULTRY SHOW.

THIS Exhibition was held in connection with the Agricultural Association, and was a complete success. The arrangements were admirably carried out by the Stewards, the Messrs. Ware, who saw to the welfare of the birds and the public. The tents were thronged, and the crowd at times was so great that it was quite impossible to move. The Judges were Mr. M. Hedley and Mr. W. J. Nicholls, who judged together, and turned out a most satisfactory lot of awards. The pens were Billett's of Southampton, and were capitally arranged.

In *Dorkings* the first and second cocks were very well grown birds, but of rather too silvery a shade for our taste. One of them reminded us very much of the cockerel passed at Ipswich without notice. Third prize went to Whites in exquisite bloom, their only blemish being white earlobes. The best hen in the class we thought was in pen 6 (Darby). Buff *Cochins* were good; a very pretty cockerel and a good hen won first. The former was, we believe, the bird first at Bath. The pullet in the second

pen was capital in colour and of a good shape. In the Variety *Cochin* class a fine pen of White chickens won first. The birds were in very good feather and condition. In the second-prize pen was one of the best hens (White) we have seen for a long time. Dark *Brahmas* were poor; the first-prize hen only is worthy of comment, and she was rather brown. Lights were better, and a very smart pair of chickens won first. They were good in shape and well shown. Second and third contained very neat but rather small cockerels. In the *Spaniards* we noticed a good pen of chickens, which took first. *Houdans* were few and fairly good. The first-prize pen contained the Bath cup cockerel and a very lovely pullet. The first *Crêves* were very fine, the pullet especially large and good. *Hamburgs* were simply miserable, while the *Game* were as much superior. Mr. Ward's cockerels were very smart and well shown, and are likely to be heard of again. The Variety class made one of the best classes in the Show. First went to the good La Flèche chickens, which won second at Ipswich; second went to splendid White-crested *Polands*; while the third prize was won by a very perfect pen of *Silbies*. The Brown *Leghorns* in Mr. Kitchen's very highly commended pen were very neat in comb and bright in colour. The Sale classes contained some good birds, notably so the first *Light Brahmas* of Mr. Pitt. *Bantams* had only one class, which comprised seventeen entries. A splendid pair of Silver-laced were first; small *Game* second; and neat White-booted third; very highly commended (Leno) a fairly good pen of Gold-laced. *Aylesbury Ducks* were good, and the Rouens better, the winners being really very fair in colour and large. In the Variety Duck class first and second went to fancy birds, shown in fine feather; and third to capital East Indians of good colour. The *Geese* and *Turkeys* were good, as they always are here.

In *Pigeons* first-class Carriers won most of the prizes. In single birds, however, a good White one came in second. We give the prize list below:—

**POULTRY.**—**DORKINGS.**—1 and 2, R. Cheesman. 3, R. A. Boissier. **COCHINS.**—*Cinnamon* or *Buff*.—1, A. Darby. 2 and 3, Mrs. A. Christy. *Any other variety.*—1, Rev. R. S. S. Woodgate. 2 and 3, R. A. Boissier. **BRAHMAS.**—*Dark.*—1, J. K. Lawther. 2, M. Leno. 3, Rev. J. P. Wright. *Light.*—1, M. Leno. 2 and 3, Capt. W. Savile. **SPANISH.**—1, J. Hunt. 2 and 3, J. Francis. **HOUDANS.**—1 and 2, R. A. Boissier. 3, Miss A. Sharp. **CRÊVES.**—1 and 2, H. Stephens. 3, Miss A. Sharp. **HAMBURGERS.**—*Pencilled.*—1, A. Livings. 2, E. Durant. *Black or Brown Red.*—1, W. Foster. 2 and 3, A. Warde. *Any other variety.*—1, G. H. Fitz-Herbert. 2, H. Ritchie. *ANY OTHER DISTINCT VARIETY.*—1, H. Stephens. 2, A. Darby. 3, Rev. R. S. S. Woodgate. **SELLING CLASSES.**—*Cock.*—1, H. Stephens. 2, R. A. Boissier. 3, F. Evans. *Hens.*—1, S. Pitt. 2, A. Darby. 3, R. Cheesman. *Pair.*—1, S. Pitt. 2, Rev. R. S. S. Woodgate. 3, H. Stephens. **BANTAMS.**—1, M. Leno. 2, F. C. Davis. 3, Rev. R. S. S. Woodgate. **DUCKS.**—*Aylesbury.*—1, G. Ware. 2, Marchioness Camden. 3, F. E. Arter. *Rouen.*—1, A. Arnold. 2, A. Ward. 3, J. K. Lawther. *Any other variety.*—1 and 2, M. Leno. 3, G. S. Sainsbury. **GEES.**—1, G. H. Field. 2, Marchioness Camden. 3, A. J. B. Beresford-Hope. **TURKEYS.**—1, A. Warde. 2, Marchioness Camden. 3, Marquis of Abergavenny. **PIGEONS.**—*ANY BREED.*—*Pair.*—1, H. Stephens. 2 and 3, J. Chandler. *Single.*—1 and 3, J. Chandler. 2, H. Stephens. **RABBITS.**—1, J. Buss. 2, C. King. 3, F. Killick.

### NORTHAMPTON PIGEON AND BIRD SHOW.

THE fifth Show of the Good Intent Ornithological Society was held in the Lecture Hall on October 7th and 9th. As a rule no show is better conducted, and as far as was in the power of the Committee all was well carried out; but irregularities over which they had no control caused such confusion as is seldom seen at any show, and no show was ever judged under greater difficulties, for at the time the birds should have been penned it was found there were about two hundred pens short, and these had to be made out of boards and wire netting, and this continued far into the afternoon. We think no one ought to undertake to supply pens unless quite certain of being able to carry out the engagement to the letter. The entries in all sections were very large, there being 856 in all, Pigeons averaging eighteen in a class, and Rabbits a little over twenty-seven in a class, or 193 Rabbits and 352 Pigeons, this being the most complete success the Society has had.

**Pigeons.**—Pouters headed the list, a White cock in splendid form taking the lead, second a Black, and third White. In hens first was the White Ipswich cup bird in the finest order, second Blue, and third Red. Carrier cocks were a grand lot. First a Dun, and second Black, beaten only in neck and style, and third Black. In hens first and second were Duns, and third Blacks—a capital lot. Carrier cock or hen of this season were very good and large entries, the winners being Black. Barbs, first a Black hen, second Black cock, and third a Red, a little pinched, but broad in skull. In Tumblers, Short-faced, all the winners were Almonds and all cocks. Long-faces were—first a Yellow Bald, second a Red Mottle, and third a Black Bald. In foreign Owls first and third White, and second Blue. Owls, English, cocks were a large entry, and there were many excellent birds, the first extraordinarily short in face, well curved, and large in skull; the second longer, but of the true type, both Blues, and third a good Silver. Hens were also a good class, although some were too spindly in beak, the winners Silver, Blue, and Silver respectively. Turbits a large class. First and third Silver, and second Blue. Jacobins were uncommonly good. First a Red, second White, and third Yellow. In Dra-

goons first was a Silver, and second and third Blues, and all by one exhibitor, and of the same type. Dragons, any other, first and second Yellow, and third Grizzle. Antwerps were not so good a class, though there were some good birds in both cases. In the Variety class first was a Black Trumpeter, second a Blondinette, and third a Black Turbitten. There were two very large Selling classes, the first in both cases being White Pouters.

**Rabbits.**—Of these there was such a show as has never before been seen for the amount of money offered. Lops were all mentioned with the exception of one crooked-legged specimen. The first was a Sooty-fawn Doe, 23 by 4½, without doubt one of the most perfect Rabbits ever seen; second a Sooty-fawn buck, grand in carriage, with very large head and eye, 23 by 4½; third a Black-and-white doe, 22½ by 5, the rest coming well up to these measurements, many being well deserving of prizes. Dutch an enormous class of thirty-four, but in quality not first-rate, there being very few anything like perfect in marking. The whole of the winners were grey. Angoras were a good lot. First a very soft-woolled Rabbit, good in all respects, and claimed at the catalogue price; second a young one, very good in wool but small; and third a fair Rabbit, well groomed, but a little coarse in wool. Himalayans were about the most even class in the Show, many more deserving prizes beside those that won. In Silver-Greys were some very good specimens, and yet none quite up to what we have seen. The first most perfect in silvering, sharp, and full of ticking, with the slightest inclination to be shady on the face; second a little more even, but duller in silvering; and third a very even Rabbit, but slightly inclined to meanness. In the Variety class first was a Silver Cream, which would be much more properly designated Silver Fawn; second about the best Belgian Hare we have yet seen; and third also a capital Belgian. The Selling class contained fifty-six entries, but on account of the difficulty with the pens before referred to it was a sad medley, and it would have been much better had the lot been divided; two extra prizes were, however, given. First was a good little Tortoiseshell Dutch, second Himalayan, third Silver-Grey; extra second Tortoiseshell Lop, 21½ by 4½. Many of these being excellent bargains.

**Cage Birds.**—Clear Yellow Norwich headed the list; the first, though not quite fine, having a few nestling feathers about the eyes, still well placed, and soon claimed at the catalogue price, £5. Quite a tussle for second honours, the third being almost equal. Buffs were a grand lot; first and second (Mr. Athersuch) out-distanced all the rest. Evenly-marked classes contained some capital specimens as regards colour and markings; first and second in each class were good. The winners in Ticked and Unevenly-marked Jonque were *unevenly* birds. Mr. Adams readily gained first and second in Ticked and Unevenly-marked Buffs with a capital pair; first a large Ticked. The Crested classes were numerous and good. First in Jonque, with the exception of being rather horned at the back of the crest, was very superior; dark crest and wings. The first in Buffs was a bird that judges were so divided in opinion upon last year, being a question of Norwich *versus* Crest and *vice-versa*. In this instance Crest won the day. The Lizard Jonques moderate; first and second Silvers were exceptionally good. Cinnamons were simply grand, though several Jonques were disqualified for being deficient of tail feathers. Any other variety of Canary or Mule, first went to a good Coppy, second a beautiful Greenfinch Mule, third a Yellow Belgian. Goldfinch Mules were a grand collection; first Mr. Salt's, late Bunting's, "Snowflake" in grand condition; second evenly Buff, same owner; third Variegated Jonque. In British birds a misnomer, White Blackbird, gained first honours. In a well-contested Selling class Mr. Athersuch took the lead with a bird fit to contend in better company.

**PIGEONS.**—**Pouters.**—Cock.—1, L. & W. Watkin. 2, J. Stiles, jun. 3, R. Fulton. *vhc.* J. Baker, C. Martin, W. Nottage, R. Fulton. *Hen.*—1, R. Fulton. 2, J. Baker. 3, L. & W. Watkin. *vhc.* C. Martin, H. R. Tenney. **CARRIERS.**—Cock.—1, R. Fulton. 2 and 3, J. Baker. *vhc.* H. Yardley, R. Fulton. *Hen.*—1 and 2, R. Fulton. 3, H. Pratt. *vhc.* J. E. Palmer, H. Yardley. **YOUNG COCK OR HEN.**—1, M. Leno. 3, C. Hillier. 3, H. Pratt. *vhc.* J. E. Palmer, W. Larkins, J. H. Smith. **BABS.**—Cock or Hen.—1, W. Larkins. 2 and 3, R. Fulton. *vhc.* J. Baker. **TUMBLERS.**—*Short-faced.*—Cock or Hen.—1, J. Baker. 2 and 3, R. Fulton. *vhc.* J. Baker, W. R. Pratt. *Long-faced.*—Cock or Hen.—1 and 2, R. Fulton. **OWLS.**—*Foreign.*—Cock or Hen.—1, R. Fulton. 2 and 3, J. Baker. *English.*—Cock.—1, W. Binns. 2, E. Lee. 3, R. Woods. *vhc.* J. Baker, J. Thresh, P. H. Jones. *Hen.*—1, J. Thresh. 2, P. H. Jones. 3, J. Barnes. *vhc.* W. Binns, R. J. Goodwin. **TURBITT.**—Cock or Hen.—1 and 2, J. Baker. 3, H. Yardley. *vhc.* J. Barnes. **JACOBS.**—Cock or Hen.—1 and 2, T. W. Swallow. 3, R. Fulton. *vhc.* G. Hardy (2). J. Frame, J. Baker, R. Fulton (2). **DRACOONS.**—*Blue or silver.*—Cock or Hen.—1, 2, and 3, R. Woods. *vhc.* W. Sugden, A. McKenzie (2), J. Baker. *Any other colour.*—Cock or Hen.—1 and 3, R. Woods. 2, W. Sugden. **ANTWERPS.**—*Short-faced.*—Cock or Hen.—1, H. Yardley. 2, J. Chandler. 3, J. J. Bradley. *Any other variety.*—Cock or Hen.—1, C. F. Herrie. 2, W. Carter, jun. 3, E. North. **ANY OTHER VARIETY.**—Cock or Hen.—1, J. Baker. 2 and 3, H. Yardley. **SELLING CLASS.**—*Single Birds.*—1, W. Nottage. 2, J. Frame. 3, R. Woods. *Pairs.*—1, W. Nottage. 2, A. Bentley. 3, T. H. and A. Stretch.

**CANARIES.**—**NORWICH.**—*Clear Jonque.*—1, F. Willis. 2 and *vhc.* J. Athersuch. 3, D. Andley. *Clear Buff.*—1 and 2, J. Athersuch. 3, West & Sawyer. *vhc.* F. Willis, Brown & Gayton. *Evenly-marked Jonque.*—1, C. J. Salt. 2, T. Cleminson. 3, J. Adams. *vhc.* Cox & Griffin. *Evenly-marked Buff.*—1, C. Hampton. 2, F. Willis. 3, C. J. Salt. *vhc.* Cox & Griffin. *Ticked or Unevenly-marked Jonque.*—1, J. Athersuch. 2, J. Adams. 3, G. E. Russell. *vhc.* F. Willis, Cox & Griffin. *Ticked or Unevenly-marked Buff.*—1 and 2, J. Adams. 3, J. Athersuch. *vhc.* F. Willis. *Any variety Crested Jonque.*—1, T. Irons. 3, S. Stratford. 3, W. J. Hampton. *vhc.* G. E. Russell, C. J. Salt. *Any variety Crested Buff.*—1, S. Stratford. 2, F. J. Knags. 3, C. J. Salt. *vhc.* Cox and Griffin, W. J. Hampton. **YORKSHIRE.**—*Clear, Ticked, or Variegated Yellow.*—1,

2, and *vhc.* J. Thackrey. 3, L. Belk. *Clear, Ticked, or Variegated Buff.*—1, 3, and *vhc.* J. Thackrey. 2, L. Belk. **LIZARD.**—*Golden-spangled.*—1, Cleminson and Ellerton. 2, T. Tenniswood. 3, T. Cleminson. *Silver-spangled.*—1, R. Ritchie. 2 and *vhc.* Cleminson & Ellerton. 3, T. Cleminson. **CINNAMON.**—*Jonque.*—1, J. Athersuch. 2, J. Adams. 3, Brown & Gayton. *vhc.* Cox and Griffin. *Buff.*—1, J. Adams. 3, Rice & Co. 3, J. Adams. *vhc.* Brown & Gayton, Rice & Co. *Ticked or Broken Jonque or Buff.*—1 and 2, J. Adams. 3, Rice & Co. *vhc.* Cox & Griffin. *Evenly-marked or Variegated, Jonque or Buff, Plain or Crested.*—1, L. Belk. 2, S. Stratford. 3, D. Audley. *vhc.* Rice & Co., J. Athersuch, C. J. Salt. **ANY OTHER VARIETY OF CANARY OR MULE.**—1 and 3, C. J. Salt. 2, W. C. Burniston. *vhc.* C. J. Salt, F. Barbour. **GOLDFINCH MULE.**—*Clear, Evenly-marked, or Variegated Jonque or Buff.*—1 and 2, C. J. Salt. 3 and *vhc.* Strou & Good. *Dark Jonque or Buff.*—1, Cox & Griffin. 2 and *vhc.* C. J. Salt. 3, W. Smith. **BRITISH BIRDS.**—1, R. Humphrey. 2, E. Martin. 3, W. C. Burniston. *vhc.* G. Mead, J. Hopkins, J. Mason. **SELLING CLASS.**—1, J. Athersuch. 2, Rice & Co. 3, F. Willis. *vhc.* Brown & Gayton, F. Willis.

**RABBITS.**—**LOP-EARED.**—*Buck or Doe.*—1, J. Cranch. 2, C. E. Thompson. 3, E. Pepper. *vhc.* T. & E. J. Fell (2). C. King (2). T. S. Barrows, A. Archer. *Dutch.*—*Buck or Doe.*—1, Mrs. H. ## CIRENCESTER POULTRY SHOW.

MAY I call your attention and that of your readers to the schedule of the forthcoming Cirencester Poultry Show? Every effort has been made to give effect to the various suggestions which have from time to time been made, so far as practicable. Amateurs specially conversant with the classes they have to judge have kindly consented to judge. Their names will be given, and the classes they undertake announced.

Some important classes, such as Dorkings and Spanish, have been left out. They have never mustered strongly, and it is thought that at local shows all classes should pay. There is still time to insert any class of which the admirers will guarantee entries. I have myself done this with the Game classes on condition that the Oxford schedule is adopted for them. If, therefore, any class is omitted the Committee will not be to blame. Finally, the Committee, though they have always paid without fail, have thought it well to announce that they hold themselves responsible for the payment of all prizes.—F. G. DUTTON, *Bibury Vicarage, Fairford.*

## THE BLUE ROCK AND THE BLUE ANTWERP.

HAVE all Antwerps the small white eye wattle? I had a bird given to me last year as a well-bred Antwerp, but it seems to me to look more like a Blue Rock as described in the various books. It has hardly a trace of eye wattle, and the little it has is rather pink. Its beak is dark, and thinner than those of other birds I have which I believe to be Antwerps, and it has only a small beak wattle. The eye is red. The bird is larger than an ordinary dove-cote Pigeon; but Blue Rocks I do not remember ever to have seen.—A. C.

[The "common Blue Rock" is the most uncommon Pigeon in England. We have not seen a true one for a quarter of a century, and then in Scotland, where some were breeding in caverns in the rocks on the eastern seacoast. As to Antwerps, they are of all types, from half Owls to birds very like dove-house Pigeons. Even at the Crystal Palace we have seen them with the frill of the Owl. This need not surprise anyone, as Antwerps were bred from Owls and Rocks. Shape goes for little. Some strains have "spindly" beaks, others thick beaks. So in regard to the wattle; we have had them with large wattles, and scarcely any at all. In the Antwerp the rule is "payment by results." The bird that homes well is the bird; colour, wattle, shape go for little. Still there is a general look which indicates the metal of which the bird is made—a something that says, "can't I fly, that's all."]

**CANTERBURY POULTRY SHOW.**—The prize list is very comprehensive, and although none of the first prizes are higher than £1, there are twelve extra prizes, including nine silver cups.

## RABBITS EATING THEIR YOUNG.

THE last four months I have bred in a warren about eighty Rabbits, which have lived for about six weeks and then disappeared. Are cats or stoats the enemies, or what takes them? Do the old Rabbits take a particular fancy for eating their young about that age?—W. H. H.

[If Rabbits eat their own young, it is immediately they are born. This is not uncommon with tame does, but we are not aware that wild Rabbits are thus unnatural. As you do not find the bodies of the young, and we infer by your query you do not, they must be killed and eaten, most probably by cats or weasels. A chemist would be your best guide as to poisons. Rabbits

only eating grass or grain, there would be no difficulty in giving poison to animals at the same place which naturally eat animal food only, as do cats, weasels, &c.]

### THE PECTOPLUME.

PROBABLY few have had the pleasure of examining this machine in the Agricultural Hall, Philadelphia, at the Centennial Exhibition.

It is the production of one of our genuine Yankee inventors, and, like many other useful inventions, was the result of a desire to lighten and shorten the monotonous hand-work on the farm.

The pectoplume, or feather-picker, is designed to pick or pluck the feathers from poultry of all kinds in preparing them for market. In addition to this it sorts the feathers, putting the quill feathers in one repository and the soft downy feathers in another.

In appearance the pectoplume somewhat resembles a large-sized sewing machine with the cover on it. The table is about 2½ feet wide and 4 long, and about the height of an ordinary table. In the centre of this is the machinery, which is operated by a treadle and fly-wheel underneath, the same as a sewing machine. The machinery consists of a wheel about 1 foot in diameter, and perhaps 2 inches thick on the outer edge; this edge or rim is provided with fingers, or "pickers," of india-rubber, so arranged and operated by mechanism, that as they come above the surface of the picker-table they clasp and pinch whatever comes in their way, and as they pass below on the opposite side open again, releasing the feathers. The light feathers are blown by a current of air over a sliding lip (which can be raised or lowered by the operator) into a shoot or spout, under which may be placed a box, basket, or bag to receive them. The heavy or quill feathers falling into a V-shaped trough before reaching this lip are picked up by an automatic hand and bunched, a bit of wire twisted around them, and thrown out into a basket or box placed behind the machine.

In operating it the person seats himself in front with his foot upon the treadle; getting the machine in motion he takes the fowl by the legs, laying it on the upper or picker-table, so that the rubber "pickers" just touch the fowl, turning the fowl sideways and spreading the legs, so that the fingers reach all parts of the fowl. The birds are dry-picked of course.

Mr. Obed Hopkins, the inventor, says he can with foot power pick a fowl clean in one minute; by horse or steam he considers it possible to pick two hundred fowls per hour. The work is rather too heavy for one person, and cannot be kept up any length of time; but with one to operate the treadle and another to manipulate the fowl a hundred birds can be dressed in a very short time.—H. OAKS.—(*Pet-Stock Bulletin*.)

### STRAW SKEPS VERSUS BAR HIVES.

So much has lately appeared in the *Journal of Horticulture* in favour of straw skeps and the whole system of bee management, that a tyro would be led to infer that all that has been done during the last century to advance the science of apiculture has been a move in the wrong direction; and although all the scientific apirians in Europe and America have adopted some modification of the bar or bar-and-frame hive, it has at length been discovered that a large straw skep with fixed combs, made doubly secure by transverse sticks, and the ultimate destruction of the bees by sulphur (which is in the majority of instances involved in this mode of management), to obtain their treasures, is the *ne plus ultra* of bee-keeping where large harvests of honey and wax are to be secured. A few remarks upon the conservative system may possibly be acceptable to some of your readers, showing that excellent results may be obtained with modern improved hives, notwithstanding Mr. Pettigrew's wholesale condemnation of moveable bars, which are the greatest improvement ever effected in apiculture, and which will never be abandoned by any who have once tried them, if they only possess sufficient skill and knowledge to avail themselves of the advantages they possess.

In consequence of what was written by "A RENFREWSHIRE BEE-KEEPER," I was induced to give the Stewarton system a trial, and the result has been most satisfactory. One hive this season has yielded me 144 lbs. of perfectly pure virgin honeycomb, and the stock from which it was taken weighed 60 lbs. nett—(i.e., exclusive of the hive), after the supers had been removed.

In 1875, the worst honey season known in this district for twenty years, this colony gave me about 30 lbs. of very fine honey, and had sufficient left for a winter supply. The bees wintered in two Stewarton boxes, each 7 inches deep; and it may be remarked, as bearing upon a controversy held in this *Journal* some years ago, that they selected the upper storey for their winter residence. Towards the end of May, 1876, two supers, respectively 4 and 5 inches deep, were put over the stock, and the two outer slides withdrawn. The bees soon took possession of the supers, but as honey was not very abundant

did not progress very rapidly, and, as the hive did not seem crowded, I was unwilling to give them additional accommodation below. The result was that a large swarm issued forth on Trinity Sunday, at about 10 a.m. The swarm was hived in a large skep, and as soon as the bees were settled was carried down into a cellar, lest one of the numerous decoy hives the tenants of which had died in the winter should tempt the bees to decamp. After midday I overhauled all the combs in the stock (see the use of moveable bars), and excised all the royal cells. The swarm was then returned to the parent hive. A third stock box furnished only with a little guide comb was placed under the colony, and a third super added at the top. The bees now set to work vigorously, so that a fourth super was soon required. On the 11th of July, finding that the three lower supers were perfectly sealed, they were removed, and contained 68 lbs. of pure virgin honeycomb. Two supers were added at the top, and upon the 26th of July the two lower supers were removed, perfectly completed, and containing 41 lbs. of virgin honeycomb. The two remaining supers were taken off upon the 6th of August, and contained 35 lbs. of virgin honeycomb. All this large amount—144 lbs.—of wax and honey was made and collected by the bees fairly and honestly from the fields, without the slightest assistance, except that the two first supers were furnished with pieces of guide comb about an inch in depth, and the subsequent supers were merely supplied with strips of plain sheet wax about three-quarters of an inch deep to secure straight combs. The whole of the honey in seven compartments was stored in perfectly pure virgin comb, and not a single cell in the whole pile contained the slightest trace of brood or pollen.

Contrast this with a Pettigrew hive. In one case you have 144 lbs. of the purest honey in seven separate boxes, each box containing seven combs, each comb fixed upon a separate bar. Any one of these boxes, or any individual comb, can at any time be utilised without the least mess and without any appreciable amount of trouble, or can be kept as it is for months if required. All has been taken, almost without the loss of a single bee. Take the Pettigrew hive, and you have a large receptacle filled with a most heterogeneous mixture. The outer combs may contain pure honey; but even these must be broken up to get them out of the skep, and all the central part of the hive is a mixture of brood, pollen, and discoloured comb. Mr. Pettigrew justly observes bar frames can never help bees, but seems to have failed to discern that they may and do most materially help bee-masters.

All my Stewarton stock boxes contain four frames in the centre, and the hive which produced the harvest I have alluded to was and is tenanted by pure Italian bees.—J. E. BAISCOE, *Albrighton*.

### BEE SWARMING WITHOUT A QUEEN.

In the *American Prairie Farmer* are given one or two alleged instances of bees swarming without a queen. They appear circumstantial in their details, yet who can believe the thing possible? There are many instances, no doubt, when a swarm rises without a queen, which perhaps may have turned back immediately after leaving the hive, or been lost in the confusion which always more or less attends swarming, but that a swarm should issue and settle so as to be hived without a queen is not possible. In one of the instances mentioned the queen is said to have been found in a bar-framed hive quietly walking about the combs some time after the issue of the swarm; but this fact, if fact it be, would only prove either that there were two queens in the hive, or that the swarm had gone off with a fertile worker. Instances of the former have been noticed in this *Journal*, so well authenticated as to leave no doubt of the fact. Are there any known instances of the latter, or can any of our apirians friends mention any instances of apparent swarming without a queen? I mean instances when a *bonâ-fide* swarm has gone off or been hived without its queen?—B. & W.

### COLOURING COMBS AND CELL LIDS.

I AM obliged to your correspondent "J. P. J." for his friendly criticisms on my remarks on this subject. I am always pleased with such fair and temperate criticism. I failed to explain how or by what means bees temper the colour of the lids of brood cells to correspond with the colour of the combs. This is of course done by using old materials, and I am unable to conceive any other mode of doing it. "J. P. J." and myself are of the same opinion and agree here.

He advances a step further than I have ever gone when he says, "My experience has been that bees never cap brood cells with new wax; but as the edges of the cells are of extra thickness, and contain sufficient material to form caps, they simply draw out the edges and so cover over the cells." This is a very nice point, which I think our friend will find somewhat difficult to prove or maintain. Shall I be excused if I ask him to give us the details of his experience on this question? All finished cells have rims round their mouths which strengthen them

much, though they contain so little materials that they are imperceptible to the naked eye, or nearly imperceptible. The lids of queen cells are clumsily made and contain a great deal of material. Drone cells also are covered with big thick lids, which are cast out of the hives when the young drones are hatched. Does our friend maintain that these lids are made solely from the rims of the cells, or do his remarks apply to cells of working bees only? If so, he has to explain how or by what means and materials the brood cells in the centre of hives are covered with lids twelve or fourteen times every year. If his experience is correct all the brood cells have new rims some twelve or fourteen times in a season, and these rims are converted into lids. He may be right, though I do not see it at present. I shall be glad to receive further information from "J. P. J."—A. PETTIGREW.

### "B. & W.'S" APIARY IN 1876.

Of the ten hives in good order as to food and comb with which I entered upon the year, only three survived so as to be worth anything by April. All the rest died of feebleness (I know not what else to call it), arising from scarcity of brood developed in autumn. This was owing to the long-continued wet weather. The same cause prevented the bees from recovering in the early spring. In fact it rained almost every day more or less up to the 30th of April. In May (not a genial month here) they began slowly to mend, but it was not till the latter part of June that the strongest of the surviving three was able to send out a swarm.

Since then they have done well, and my three hives have given me about 70 lbs. of excellent honey, besides a couple of swarms, to which I have added two other swarms. I do not find that my neighbours on the whole have come up to this mark, so that the result of this year's bee-keeping adds to the conviction I have long formed, that our part of Somersetshire is about as bad a honey-producing county as any in Great Britain.—B. & W.

### BEEs WORKING ON A PINE TREE.

THOUGH I am but a beginner in bee-keeping, I am deeply interested in anything concerning the habits and management of bees. There is a fine specimen of *Pinus pinsapo* growing in this neighbourhood, which for three months past has been the constant resort of thousands of bees, so that the tree is in one continual hum, especially in the early part of the day. Since the cool weather has set in wasps seem to have taken possession, and may be seen clinging to the tree in great numbers, making it unsafe to disturb the tree in any way, as scarcely a branch of it is free from them. Perhaps some of your numerous correspondents would through your Journal enlighten me as to why such preference is given to this tree.—R. W. R.

[If any readers have witnessed bees working on pine trees I shall be glad if they will give their opinions as to the matter or stuff the bees were gathering. I fancy—and it is only fancy—that the tree above mentioned is in a state of disease and covered with an insect, probably a small aphid, which ejects a sweet matter well known as honeydew. The fact that the bees were most busy in the early part of the day indicates that they found more stuff than in the afternoon. I have never seen bees working on pine trees, but my father went into his garden one morning very early, and found his bees hard at work, coming home heavily laden from a plantation of Scotch firs. He went amongst the trees and found the bees were gathering a clear shining substance from the leaves of the young Scotch firs. He did not then suspect that the matter gathered was the exudations of an insect. This happened before my day. The honey gathered that year, according to my father's account, fermented in the hives and destroyed many of them. In no other season did he ever find the bees working on the Scotch firs adjoining his apiary.—A. PETTIGREW.]

IRON DURING MOULTING.—A good article to use in the water given your moulting fowls to drink is the tincture of iron. It is very handy and cheap, and should be accessible constantly during the critical time when old fowls are changing their plumage. It is strengthening, palatable, and works like a charm in its way as a stomach tonic. A tablespoonful of the tincture to a quart of water is sufficient. To be had at any drug store.—(*American Poultry Nation.*)

### OUR LETTER BOX.

HATCHING APPARATUS (R. A.).—Not one that has yet been invented has ever proved satisfactory.

YOUNG POULTRY DYING (J. Whitaker).—You say that none of the old birds die, are they fed together? There was nothing apparently injurious in the wheat you sent, and the birds sent are in good condition. Their crops were empty. We think there must be something poisonous eaten by them.

UNDEBBED GAME COCK (C.).—A medium-sized comb is preferable to a large comb.

BANTAM'S EYES SWOLLEN (F. W.).—We do not know what fluid you mean, but eyes are too delicate to be trifled with. Apply goulard water, taking care that it does not touch the eyeball.

CRYSTALS ON PAMPAS GRASS (Mrs. W.).—A saturated solution of alum will deposit them.

TAKING HONEY (Inquirer).—It is not too late to take the honey from your straw skep, but of course you will find less of it than if you had robbed the bees six weeks ago, unless you are fortunate enough to live near heather. If you take all the honey you had better unite the bees to some weaker hive.

SMOKING BEES—EXAMINING HIVE (A. del B.).—1st, The other day I bought a hive of bees, fastened to a stool without a board. Wishing to put it on a board, I set fire to a piece of fustian rag and began blowing the smoke into the hive, when the bees rushed out upon me. Why did they do this? 2nd, What is the proper way to turn up a hive and look into it? 3rd, Can you turn up a hive at any time in the year without injuring the bees, or the bees injuring you? 4th, In smoking or turning up a hive do any of the bees fly about. 5th, When a bee attacks you, is there any sure means of not getting stung? In answer to our correspondent's first question we have to say that the bees rose before they were mastered or affected by the smoke. Being without a board it was difficult to apply the smoke so as to master them. Before a hive is examined it should be well smoked and then gently turned up, and held on the knee or turned up and placed on the ground with the combs and bees exposed to view. As the smoke of fustian rag does no harm to bees, beginners should apply it in abundance in examining hives in summer. Bees may be examined at all seasons without injuring them, but, as bees have weapons of defence and wills of their own, we dare not say that they will let the bee-master do as he likes and go scot-free and unscathed. If bees do attack there is no sure way of not getting stung.

### REMARKS.

4th.—Rain early, then fair but cloudy; a fine day after 10 A.M., splendid sunset, and fine night.

5th.—Fine morning, fine enjoyable day and night.

6th.—Morning hazy and damp; fine after, but very warm and close.

7th.—Dull and showery all day, and at times very dark.

8th.—Hazy damp morning; rather better in the afternoon, but the stones damp all day.

9th.—Wind rose rapidly about 2 A.M., and was high all the early part of the day, with frequent slight rain; very bright for a short time in the middle of the day.

10th.—Wind and rain in the forenoon; gradually improving as the day advanced.

A warm but not pleasant week, the atmosphere heavy and damp; rain daily since the 4th. Temperature nearly 6° warmer than last week.—G. J. SYMONS.

### COVENT GARDEN MARKET.—OCTOBER 11.

THERE are no alterations in prices from last week. Business remains the same.

From observations taken near London during forty-three years, the average day temperature of the week is 58.1°; and its night temperature 40.1°.

## FRUITING VINES IN POTS.

**N**EARLY every gentleman's garden contains a number of Vines which are fruited yearly in pots, and many amateurs who have no established vinery grow Grapes regularly in this way. The growing of Vines in pots for planting and fruiting has become quite an important branch of commerce lately, and some who give special attention to Vines in pots produce them in fine condition; and as the prices are always reasonable, it is generally the best and cheapest plan to purchase the Vines from some establishment where they are known to be good.

For very early forcing the Vines must be two years old. For instance, those propagated from eyes this spring and grown on throughout the summer will have made good-sized canes which will now be approaching maturity. Early in January the canes are cut down two or three eyes from the root, and the pots are plunged in a bottom heat of 70°. In this the eyes soon start into growth, and when the shoots are a few inches long the pots are taken from the bottom heat and set on the surface of the plunging material for a week or so before turning the roots out of the pots, reducing the old ball of soil and repotting. After this they are again placed in bottom heat until growth has begun, when they are removed to a hard dry bottom of some sort; and at the same time, if all the eyes which were left have started into growth, the whole of them are rubbed-off but one, which is encouraged to grow into as good a cane as possible. These Vines are known as "cut-backs," and when properly managed they are about half grown before those raised from eyes the same spring are started into growth. Of course this great difference at the beginning holds good throughout the season, and consequently the cut-backs are full-grown canes and quite ripe very early in the season—say in July, which is generally the case. Being ripe at that time gives them the advantage of a long rest, and adapts them for starting very early in autumn.

When ripe Grapes are wanted on pot Vines early in April it is necessary to place the Vines in their forcing quarters in October, but it is no use trying to accomplish this unless with cut-back Vines; therefore, let me impress on those intending to start Vines in October to begin with nothing else but thoroughly sound and well-ripened canes of this description. Hard brown wood, and firm well-developed buds, are sure indications of a good cane; but those with no great knowledge of Vines should leave their selection to the person they buy them from. Before placing them in their fruiting quarters each cane should be washed with a brush and soft soap and water, rubbing well about the buds, as insects generally harbour there. Should the canes show spots of mildew brush them over after washing with a mixture of soot, sulphur, and milk. This checks the further progress of this most troublesome pest, and it is much easier dealt with when the leaves are off than on. After washing turn the ball carefully

out of the pot, and see that the drainage at the bottom is in working order. This may be done by lifting straight up by the cane; and if the roots are in good condition the ball will lift entire, and may be dropped into the pot again without a single root being displaced. As the drainage of each one is seen to be correct, after the ball has been returned to the pot scrape away all the surface soil well down into the roots, and top-dress with a rich mixture of loam and cow dung, bringing it firmly up to within 1½ inch from the top, when the remainder of the space may be left empty for receiving water. When this has been completed the Vines are ready for forcing.

In many places there is a small house especially devoted to fruiting Vines in pots, and in such structures there are mostly properly constructed beds, &c., for the Vines to start in. A little bottom heat is a great advantage to the Vines at first, especially in October and November, when they are much more difficult to start into growth than further on in the season. If they can be plunged in a leaf or tan bed where the bottom heat is about 65° or 70° let them be so by all means, and where there is no such convenience set the bottoms of the pots on the hot-water pipes, or some such place, where they will have the benefit of a little heat. For a few weeks at first the rods should rest down near the ground. If the pots are in a bed let the canes rest on the surface, as they are then more in the way of moisture than when tied up to a dry roof. When the pots are plunged not much water is required at the root until the Vines are in leaf, but much more is needed when they are standing on the pipes. When the drainage is right they are not easily injured with too much water at the roots. The canes must be syringed morning and night. For the first three weeks the heat of the house should not exceed 55° at night and 65° during the day, and excepting during the time they are in bloom the temperature should not rise more than 5° above these figures until after the fruit is set. A high temperature to begin with, or indeed at any time throughout the short days, weakens the shoots and greatly diminishes the strength of the Vine; whereas a low temperature at first is always favourable to robust growth and substantial fruitfulness, and when once this is established a high temperature has no injurious influence.

It is tedious work waiting for Vines coming into leaf in November, but they come on gradually, and as soon as the shoots are about 1 inch in length the canes should be tied up into their permanent positions. There may be a number of shoots starting from the base of each bud, and as the canes are tied up all the shoots excepting the strongest should be rubbed off. As the shoots become long they must be fixed to the wires with a strong piece of matting, and when the bunches are formed the shoot should be stopped one or two joints or leaves beyond them. When they are forward enough to admit of this being done they are not far from coming into flower. During the time they are in bloom the temperature must not fluctuate much, and throughout all their early growth in the winter time cold draughts must be

particularly guarded against. Insects, such as thrips and red spider, are not very apt to appear in great numbers in the short days; still, when much fire heat has to be used to keep up the temperature these insects do sometimes become troublesome on early Vines, so that syringing should not be neglected whenever they are known to exist, and the atmosphere should always be kept moist, as this not only tends to keep the foliage healthy; but insects seldom do much harm when the air is in a moist condition.

In very early forcing a good deal of the battle is over when the fruit is formed, and the Vines make much quicker progress after this time than before it. As soon as the fruit begins swelling liberal supplies of manure water must be given two or three times a-week at the roots, and this may be continued until the fruit begins to change colour, when nothing but clean water should be given. Most pot Vines produce more bunches than is sufficient for a crop, and before thinning is commenced all the bunches that are not wanted should be cut off. Of course the worst are always removed first, and the best shaped and set bunches left for the crop. From six to ten is an average crop, but this must be regulated according to the size of the bunches and strength of the Vines; however, it is always better to have one or two bunches less than more than what the Vines will finish properly. When the berries are about the size of peas they must be thinned. Here again it is difficult to say exactly what should be taken or what should be left. In an ordinary way about the half may be thinned out, and the remainder must be left as evenly all over the bunch as possible. After the Grapes are thinned the Vines will bear pushing-on in a higher temperature than they have been growing in up to this time. From November to March there are generally not many opportunities of admitting much air, but the top ventilators especially should always be opened more or less on every favourable opportunity, and sun heat during the day is always preferable to fire heat to keep up the desired temperature. Moisture in the air and at the roots, and stopping the shoots as they grow, are the principal requirements during the latter part of their growth.

In many instances pot Vines are not started so early as October; December and January being the months when most are introduced to their forcing quarters. At this time, or any other throughout the winter, they should be treated as recommended above, as the difference in the time of starting makes no alteration in their cultivation, excepting they grow much quicker as the season advances. It is mostly gentlemen's gardeners and market gardeners who grow Grapes on pot Vines so early, as they save the energies of their planted-out Vines. Amateurs who only grow Grapes on the pot system do not, as a rule, start them until March or April. Their cultivation from then onwards is very simple and far less expensive than in the winter time. In good summers they may be grown without the assistance of any fire heat, and it is nothing like such a difficult matter getting the fruit well coloured in long bright days as in short dull days. Much more water is needed at the roots in the summer time, and more attention is generally required to prevent insects from doing harm. Further than this, their treatment as regards tying, stopping, thinning the bunches, fruit, &c., has to be done in the same way at all times.

When the fruit is ripe the cooler it is kept the better, and after it is cut the foliage should be thoroughly well syringed and cleaned, if the Vines are wanted to fruit the following season. In this case the shoots must be well ripened, and when the leaves have dropped they may be pruned, cutting each shoot back to two buds from the main stem, and washing and top-dressing them as was done the former year. They seldom bear such a fine crop the second time, and many find it most profitable to start with fresh canes every year. For midsummer fruiting, or starting into growth after the days begin to lengthen, it is not necessary to use cut-back Vines. Those raised from eyes and well grown the previous summer, although late in ripening, have a long rest during the winter, and generally fruit and succeed well the following season. These canes are often better to keep for fruiting a second time than the cut-back canes which are older in the root.

Nearly every variety that does well planted out may be fruited in a pot; still there are some better adapted for pot culture than others. The Black Hamburg is the very best for early fruiting, and amateurs seldom fail with it at any time. Gros Colman and Alicante are good late blacks; but late sorts are not so much fruited in pots as early sorts. Amongst early whites Royal Muscadine and Buckland Sweetwater are two well-tried

kinds. Foster's Seedling is not worth growing, as it has no flavour. I have not much experience yet of Duke of Buccleuch in a pot; but while speaking to Mr. W. Thomson the other day he told me he did not care if he did not sell a fruiting cane of the Duke this season, as he would rather keep them and fruit them; so if he can make more by fruiting them than selling the canes at half a guinea each, it speaks pretty well of its worth as a pot variety.—VITIS.

## ASTERS.

THE Aster is one of the most useful of autumn flowers, and it is the more valuable because it can be cultivated and brought to a high state of perfection by those who have no glass houses. The flowers last long in beauty if left on the plants, and for cutting and placing in vases they are much valued. I heard the remark frequently made last season that Asters had done badly; another says "My Asters are poor this year." Now, Asters will always do well if care is taken of them, but they must be watched from the time the seedlings appear until the flowers open.

It is not necessary to sow the seeds under glass; but when a frame can be had with a little bottom heat it is better to do so, as a larger proportion of seeds will germinate in a frame, and the plants grow more strongly in frames for the first few weeks than they do in the open air. The young plants ought to be pricked out as soon as the first leaf is formed. I sow the seed in shallow boxes and also prick out the plants into boxes, allowing sufficient space between the plants so that they may form a stubby compact growth. In their young state they are liable to be attacked by green fly, and this causes the leaves to curl. The best way to destroy the fly is to place the boxes in a house or close frame and smoke them with tobacco, or the insects may be destroyed by washing the plants with soapy water to which has been added tobacco liquor. Asters like a good rich soil well trenched and manured: a soil that would grow good Dahlias would also grow Asters well. The plants may be put out about 6 inches or a foot apart according to the variety. Some sorts will grow between 2 and 3 feet in height, others only a few inches. Until this season I have always grown the dwarf French Chrysanthemum-flowered, the French Pæony-flowered, and the Victoria in preference to the German or Quilled Asters. The above sorts are generally very free-flowering and are of dwarf habit.

After having seen the fine Asters shown by Mr. Betteridge I was this year tempted to give his sorts a trial, and can recommend them as being of a very superior strain and quite indispensable to the exhibitor. They are also preferred to the other sorts for furnishing large vases. The florets are most symmetrically arranged, forming a perfect ball, or rather half ball, at the base of which the outer petals project and form the guard petals. Snowflake and Purple Prince are selfs of the largest size and high-class quality. The first-named has the most perfect flowers, but the other has them of the largest size. Prince of Novelties and Princess Alexandra may be named together as being most striking flowers and very distinct. The guard petals and outer rings of florets are reddish crimson, the centres being pure white. In some of the flowers the white is distinctly marked, in others splashy; and I had a most beautiful flower with light crimson guard petals, while the centre florets were pure white. There are also blue flowers with white centres, also rose-coloured flowers, rose with white centre, &c., comprising at least two dozen distinct varieties. Betteridge's Asters are far superior to the German varieties, and it is a question whether we cannot raise our own seeds instead of importing seeds from Germany and France.—J. DOUGLAS.

## TROPÆOLUM SPECIOSUM.

I AM in a position to endorse every word "A RAMBLER" says about this gorgeous creeper as far as Kenmore toll-house is concerned; and further, I would say that if "RAMBLER" could have had a peep over the railing and bushes to the front of the cottage, about 30 yards from the toll-house on the same side of the road towards Kenmore, a sight of that plant would possibly have been obtained which would have gone far to have put the effect referred to in the shade. This plant is, as "RAMBLER" says, perfectly hardy, requiring no protection or care whatever beyond providing some sort of trellis for it to climb on. The soil in which it is growing there is not of the richest description, but, on the contrary, it is light and porous.

The border in front of the cottage to which I refer, and in which I once lived, is made up to a considerable depth with stones to act as drainage to the cottage, and the soil on the top of these contains a portion of old lime rubbish, and the plant grows there with greater luxuriance than any Canary plant I have ever seen.

I am trying to establish the plant here from those, and I have been successful so far, but it will take years to establish itself in any place like what "A RAMBLER" saw of it at Kenmore toll-house. It has been there now, to my knowledge, for nearly ten years, and it was established there before I saw it; and to see it there now in full flower is a sight not readily to be forgotten.—JAS. FAIRWEATHER.

### GREEN CARPET PLANTS.

SINCE that easily grown and extremely accommodating plant *Tagetes signata pumila* was planted in the beds at the Crystal Palace, the necessity for employing green in carpet-bedding designs has become firmly established. The introduction of green into beds of coloured foliage was a bold innovation, for until then the grass surrounding the beds had been considered sufficient of that neutral colour. That the judicious employment of dwarf plants with green foliage is not only permissible but advantageous for associating with such plants as Golden Feather, crimson *Alternantheras*, &c., many of the best beds both in the public parks and private gardens testify. The green divisional bands separating the brighter panels have added greatly to the finished effect of the beds, and green carpet plants at once became popular.

As was to be expected, other dwarf-growing green carpet plants than the *Tagetes* were sought for, and the result is that some of them have proved extremely suitable for carpet bedding. With the undoubted advantages of the *Tagetes*—its ready growth from seed and its elegantly cut and bright green foliage—must be considered the disadvantage that to keep it sufficiently dwarf and constantly green continued pinchings must be resorted to. That not only involves considerable labour, but the result, especially towards the end of the season, is not always satisfactory. After the pinching has been over and over again repeated the plants become stubby, and instead of the feathery-green surface which is so pleasing, the plants show the pinched stems which destroy at once the softness and smoothness which render the lines so attractive.

In order to obviate the labour of pinching, and as seeking to produce a low smooth carpet of green, *Cerastium arvense* was last year introduced into the carpet beds in Battersea Park. At the first sight this plant was considered a success, but as the season advanced its popularity decreased, its colour being too dull to be permanently satisfying, and it has only been employed to a limited extent during the present season. Taking, therefore, the two plants, *Tagetes* and green *Cerastium*, the former is still the most generally useful, although the latter is not to be despised, especially as it needs no pinching.

Other substitutes for the *Tagetes* have this year been sought for at the Crystal Palace, and in the excellent beds there some of the dwarf *Saxifrages* have been employed, such as *Saxifraga hypnoides*, *S. Gmelini*, and others; also the green *Mesembryanthemum cordifolium*. The latter plant, which grows more vigorously than *M. cordifolium variegatum*, is too robust for the chaste designs of small beds; and the *Saxifrages*, while being both dwarf and green, have a more or less tufty appearance, and cannot be considered as perfect green carpet plants, and so far as these plants are concerned the *Tagetes* is still not superseded.

But there are other plants remaining to be noticed, and these we find in a private garden the fame of which has become widely spread. In Mr. Ralli's garden at Cleveland House, Clapham Park, are two green carpet plants which may be fairly considered to take the foremost place in carpet-bedding arrangements, and which cannot fail to be largely used where this style of flower-garden decoration is adopted. Both these plants are hardy, both are of a bright refreshing green, and both are dwarf requiring no pinching. Mr. Legg, besides having the honour of producing the most perfect carpet beds which have yet been seen, has the credit of introducing into this mode of decoration the two perfect green cushion plants, *Sedum Lydium* and *Mentha Pulegium gibraltaria*. Hundreds of people have by the kindness of Mr. Ralli seen these plants during the present season, and in all probability not one has been able to find fault with them. That in these days of criticism is high praise.

It is certain that these plants will spread largely and will be planted in many gardens next year. Both are extremely effective, and they serve two distinct purposes in carpet bedding. For narrow lines, chains, and connecting links the *Mentha* is pre-eminently suitable. For this purpose no other green cushion plant can approach it. At Cleveland House it is planted in a series of loops, like the links in a chain, down the centre of a long bed, the spaces between the links and the angles of the bed being filled with very dwarf plants of Golden Feather. It is an extremely simple arrangement; but few, if any, beds outside the same garden can be found which are equally striking. In all probability the ground on which the *Mentha* chain is laid has been slightly raised above the general level of the bed. At any rate the *Mentha* shows clearly and distinctly above the golden ground of the *Pyrethrum*. Anything in its way more effective than this combination of green and gold can scarcely be imagined.

But while the *Mentha* is specially adapted for lines of say 6 inches in width, *Sedum Lydium* for forming a broad expanse of green as a groundwork, for a pattern wrought out in brighter colours, is particularly suitable. In the flower garden referred to this *Sedum* is employed in both ways—that is, it is made to form green divisional lines 5 or 6 inches wide separating brighter colours, and it is also employed in a broader expanse and forms the groundwork for a coloured design. In the former case it is effective, but in the latter it is especially charming, and it is possibly the finest of all dwarf bedding plants for producing a broad groundwork of the brightest green. In order, however, that it may continue really green and refreshing it must be planted in good soil and be kept regularly supplied with water. If planted in poor soil, or allowed to become very dry, the foliage is apt to turn brown, which considerably mars its beauty. It is free-growing, attaining a height of 3 or 4 inches, producing a cushion-like surface at once close and elegant.

Both this *Sedum* and the *Mentha*, as before remarked, are perfectly hardy, which renders them the more valuable. They are sure to be much sought after by those who "go in" for carpet bedding, and no small credit is due to Mr. Legg for showing the great decorative qualities of two such useful plants.

The *Mentha*, it may be useful to add, is a *Pennyroyal*—the Gibraltar *Pennyroyal*, and apparently differing from the English type in the more erect growth of the former. Possibly there will be those who will now try our old garden herb as a green carpet-bedding plant, which may, perhaps, be elevated from an obscure corner in the kitchen garden to a prominent place on the terrace; in the flower garden it may yet become popular, especially if it is known by its name of *Mentha Pulegium*; "Pennyroyal" would scarcely do near the drawing-room windows. The fame of its Spanish congener is already established as the foremost of green cushion plants for artistic gardening.—A PARK GARDENER.

[The *Mentha* alluded to is probably the *M. Pulegium erecta* of Miller. Miller states that he grew seventeen species or varieties of *Pennyroyal*, and the one in question he had from Gibraltar. It speedily became popular in this country as a market herb, its taller growth rendering it better capable of being cut and tied in bunches than the English *Pennyroyal*. Apparently the same plant is mentioned by Don under the name of *M. Pulegium tomentosa*, which name is appropriate, for the stems and leaves of the plants are downy, although this is not perceptible unless it is closely examined, its general appearance being bright green and shining. By Wildenow it is named *M. Pulegium gibraltaria*, and it is simply noticed as a variety of the common *Pennyroyal*.—Eds.]

### CRAWFORD'S EARLY PEACH.

NINE years ago in renewing the trees on a south Peach wall at another residence belonging to my employer I, amongst others, had two trees of the above variety planted. These, which were subjected to ordinary treatment, have done well, and produced in common with the others good crops of regular-sized fruit of average quality. I was so much struck with the appearance of the fruit on these trees that I determined to introduce the variety into the gardens here, which I did in the spring of 1872, where under my personal management it has fully sustained its good character, and I have been rewarded with some examples of fruit which have surpassed even such

kinds as Noblesse and other large kinds on the exhibition table. I consider Crawford's Early to be as reliable in its bearing properties as other kinds; such has been the result of my experience of it here.

All practical men must admit that the yellow-fleshed section of Peaches has not yet attained the excellence which some of the light-fleshed sorts, as Royal George and kindred kinds, possess. At those places where space admits of only two kinds of Peach trees being cultivated Crawford's Early may with propriety be omitted; but, on the other hand, with those whose means will allow more variety by all means plant it, as it is a desirable variety, and under suitable conditions of cultivation it will reward the grower with not a few noble examples of the most attractive Peach in cultivation.

Possibly the dish of this variety which I contributed at the meeting of the Royal Horticultural Society's Fruit Committee, September 6th, which obtained a cultural certificate, is one of those referred to by your correspondent Mr. J. Taylor; and as the extra fruit which were supplied beyond the requisite number for the dish on that occasion were all consumed, that is not a bad comment as to its quality.—GEORGE THOS. MILES, Wycombe Abbey.

### GREASY COAT APPLE.

THIS local name strikes one as being very appropiat to the Apple referred to by "J., Lincolnshire," and "J. J., Lancashire," and, like them, I think there are few if any to excel it as an autumn culinary Apple. From the description given of it in the Journal, page 298, I have no doubt of it being the same variety known in some parts of Scotland as the Irish Codlin, Manks Codlin, and Irish Pitcher of Dr. Hogg. The Apple is grown here, but I regret to say we have no fruit of it this year, or I should have had much pleasure in forwarding you specimens for examination, that you might be the better able to compare them with descriptions and examples from your other correspondents.—J. F.

[Manks Codlin and Transparent Codlin are distinct sorts. Both are excellent autumn Apples, and both have greasy skins.—EDS.]

### ROYAL HORTICULTURAL SOCIETY.

THERE appears to be a very laudable disposition on the part of those who are interested in the success and advancement of horticulture at the present time to do whatever lies in their power to promote the usefulness and welfare of the Royal Horticultural Society—a Society which, notwithstanding the great benefits it has conferred on the country, has fared as badly as if it had been guilty of some great national crime. The tide of public opinion has lately turned in its favour, and it is to be hoped that this will go on advancing till the Society receives that justice which is its due. The dissensions promoted and fostered by a small party of local Fellows at South Kensington, who thought more of their own little wants than of the common good, have served for several years past to keep the Society in a state of chronic dispeace, and the only result of their agitation has been to bring about such a state of things as will in all probability deprive them of the use and amenity which an agreeable promenade has for some years past afforded them.

The result of all this points to a termination of the agreements between the Royal Commissioners and the Society; and thoughtful men, foreseeing what must inevitably arise, are considering in what way the Society can best be constituted for the future. We publish to-day two such propositions, one by Lord Alfred S. Churchill and the other by Mr. G. F. Wilson. We commend both to the consideration of the Fellows, and without giving a decided opinion upon either we hope that the subject will receive careful consideration, and that some useful and practical scheme will be devised. All we can say for the present is that we trust the Fellows will stick by the Society, and thereby enable it to start a new life with as great or greater vigour than it has yet manifested for some years past.

THE question of reconstructing the Royal Horticultural Society is beginning to attract attention. It is high time that it should do so, and that some definite scheme should be prepared before the annual meeting of the Society in February next.

If the horticulturists throughout the country could only agree upon the principles on which this could be best effected it would materially strengthen the hands of the Council in

their negotiations with the Commissioners. It is the belief that the Society is past resuscitation that has induced the Commissioners to treat it in the cavalier manner they have done lately.

I enclose the outline of a scheme as a basis on which the Society's reconstruction could be effected. In doing this I have no wish to put it forward as the only one likely to answer; it is solely my own idea, which I submit for consideration in conjunction with others that may be proposed.—ALFRED S. CHURCHILL.

#### SUGGESTIONS BY LORD ALFRED S. CHURCHILL.

1. Bye-laws to be altered.
2. Fellowships, £2 2s. No entrance fees.
3. Associateships, £1 ls.
4. Gardeners in the employment of Fellows, 10s. 6d.
5. All voting power to be confined to Fellows paying £2 2s.
6. Provincial shows to be encouraged.
7. Quarterly journal to be published and supplied gratis to Fellows. Associates to pay half price.
8. Fellows, Associates, and subscribing Gardeners to have free admission to Chiswick Gardens, and to all shows either in the provinces or in London given or promoted by the Royal Horticultural Society.
9. Fellows and Associates to have the power of admitting friends to Chiswick either by order or personally.
10. Provincial horticultural societies subscribing to the Royal Horticultural Society five guineas per annum to receive two silver and two bronze medals, also copy of journal. Ditto subscribing three guineas, to have two bronze medals and journal only. N.B.—And so on for every five or three guineas subscribed.
11. The President or Secretary of subscribing societies to be an *ex-officio* Fellow of the Society during the time he may continue to hold his office, and to vote at all meetings on behalf of his society.
12. The Secretary of Royal Horticultural Society to open communications with foreign horticultural societies, and publish a precise copy of correspondence in journal.
13. Shows and meetings to be held in London by arrangement with Her Majesty's Commissioners.
14. Scientific Committee to be held as at present, and verbatim reports of proceedings to be published in journal.

#### SUGGESTIONS BY MR. G. F. WILSON.

REASONS for joining the Royal Horticultural Society as Fellows paying guinea subscriptions:—

The Society is doing important and useful work, which benefits all who value their gardens or who care for fruit, vegetables, or flowers.

The Scientific Committee is now the recognised authority on all subjects connected with plant life, disease, and plagues, and does much other valuable work.

Its Fruit and Floral Committees examine new fruits, vegetables, and flowers, work which can only be done by a great central society. Their judgments, immediately published by means of the gardening press, are now received with respect, and acted upon all through the country.

In the Society's garden at Chiswick flowers, fruit, and vegetables are grown side by side, are tested and judged by the highest authorities, and troublesome synonyms got rid of.

The Society, being relieved from the heavy charge of South Kensington, will have only Chiswick Garden to keep up, and to provide for shows and committee meetings if possible at South Kensington, otherwise in the neighbourhood; the great country shows will be self-supporting.

The guinea subscription will enable good horticulturists to come into the Society from every corner of the kingdom.

It is hoped that some of the old supporters of the Society who have long paid their four-guinea subscriptions will, at least for a time, continue to do so, and that some wealthy and enthusiastic horticulturists will join their number. The subscribers of not less than four guineas will be called Patron Fellows.

As soon as the Council of the Royal Horticultural Society can arrange with H.M. Commissioners of 1851 in the interest of the debenture-holders the lease of the South Kensington Garden will be surrendered, and it may be expected that the subscriptions of those Fellows who paid to get the exercise ground for their children will be discontinued. It is therefore most desirable that new Fellows should be in readiness to supply their place. It was lately suggested to form a large and influential Committee headed by the Editors of the four leading London horticultural journals (to show unanimity of feeling, at least in the leaders). This Committee to bind itself to nothing but to aid in bringing in guinea Fellows when the Society is freed from its present incumbrances. Three out of the four Editors have given their names; the fourth, being Secretary of the Society, can hold no other position.

Very influential gardening names have already been received

and are constantly coming in. It was decided not to publish names till the list was a very long one.

The privileges which can at present be stated as accruing to the guinea fellowships are admittance to all the Society's shows in London and in the provinces, and to all minor exhibitions of fruit and flowers held at the fortnightly Committee meetings, and daily admission to the Chiswick Gardens (Sundays excepted).

I, the undersigned, authorise you to add my name to the list of Fellows of the Royal Horticultural Society paying an annual subscription of one guinea, upon the understanding that I incur no further liability.

\*I further consent to my name being placed on the list of the Committee now being formed to aid in obtaining a large accession of Fellows at the same rate of subscription.

Signature,

Address,

\*This to be struck out if there is an objection to joining the Committee.

## NOTES OF A SCOTTISH TOUR.—No. 5.

HELENSBURGH, LOCH LOMOND, AND EDINBURGH.

I HAVE already, in writing of the West of Scotland Rose Show, alluded to the thriving watering place Helensburgh, and to the thoroughly hospitable character of the welcome I received; my recurring to it again is for the purpose of saying a few words on the establishment of Messrs. Robertson & Galloway. I am the more induced to do this because of the very prominent position taken by Mr. Galloway as an exhibitor of one of my favourite flowers—the *Gladiolus*, and I was naturally desirous of seeing him and his flowers at home. Unfortunately, as far as the nursery was concerned it was an unpropitious time, for they were about to remove, and consequently everything was in a transition state; but I saw enough to convince me that the same energy and skill which have enabled one of the firm to occupy so leading a position as a grower of *Gladiolus* is being carried out in the other departments of the business.

It is at Mr. Galloway's own house or cottage that the cultures of the *Gladiolus* are carried on; and I was perfectly astonished to find so small a space occupied by them, when I recollected that he had come up some three hundred miles and had beaten, and well beaten, our champion grower on his own ground (a feat he has since repeated at the last Crystal Palace Show), and to find that he only grows about two thousand bulbs in all. And what is still more remarkable, he has violated all the rules given as to growth, for the bulbs have been planted in the same ground year after year, and there is nothing which we have all insisted upon more than that the ground should be changed every year. I could not find that there was any special mode of culture, nor was the soil anyway remarkable. There must be something in the management of the spikes when they commence flowering that tends to this success, for at the time of my visit the plants were not a bit stronger than my own—I question if so strong, but I could not exhibit such spikes as he produced at the Crystal Palace. It may give some idea of the general character of his plants when I say that these two thousand bulbs are planted on a piece of ground that measures only 2200 square feet, and that out of them Mr. Galloway had cut 258 blooms of fine quality, mostly with eleven or twelve flowers out on each; that he had exhibited at thirteen different shows including the great international one at Dundee and the Crystal Palace, at each competition he had invariably gained first prize, and that even when brought into competition with such renowned growers as Mr. Kelway. It is evident, if we are ever to have autumn shows again about the metropolis, account must be taken of Mr. Galloway as a most formidable competitor.

There were many charming villa residences about Helensburgh of which I should have liked to have seen more had time permitted. My most kind host, Mr. A. Craig Robertson's beautiful house and grounds were in their way the very perfection of arrangement, and a few years will add greatly to their charm; and I have no doubt there were many others. The residence of Mr. Crum Ewing, M.P., too, seemed to present many attractions, while the shores of the Gareloch contain many favourite homes of Roses and other flowers.

And what shall I say of Loch Lomond, Loch Katrine, and the Trossacks? The hope of many years was at last fulfilled; and a most pleasant day, made doubly so by the valuable escort of my excellent host, enabled me to see the last of the European lakes that I hoped to visit. In my salet days I had visited the Italian, and in mature years the Swiss lakes. I had as a young man explored the beauties of Windermere and

the other English lakes. Killarney, Lough Neagh, and the other Irish lakes were familiar to me; and now I have seen the chiefest of the Scotch lakes. It would ill become me to attempt a description of this day's charming tour; moreover, I must stick to my last and keep to horticulture. And here let me say I was (as your correspondent would have seen had he turned to a back number of these notes) equally struck with himself with the extreme beauty of *Tropæolum speciosum*, which grows so luxuriantly all along this region of Scotland, perfectly hardy, and, as I was told, almost a weed in some places. Whether in our drier climate we shall succeed with it I know not, but I mean to try it this year (having been promised some roots of it) in various aspects. One great point is, I believe, to leave it undisturbed; and it will be almost necessary with us to give some protection to the roots in winter, removing the covering as soon as ever the roots begin to move. It is somewhat singular that so beautiful a plant should be so rare in the south of England, but a great many persons to whom I have spoken about it do not seem to know it even by name.

If it be difficult to describe such scenery as Loch Lomond and the Trossacks, it is equally so to describe the exceeding beauty of Edinburgh. I have seen many cities, but I confess I was never more impressed with the beauty of any than with that of the modern Athens. Some cities, as Naples, owe nearly all to nature; others, as Paris, nearly all to art. And if there be nothing in Edinburgh to vie with that wondrous view over the Bay of Naples, with Vesuvius towering above and Isola and Procida set as gems in the blue sea, or nothing to compare with that view, equally wonderful in its way, which one gets, or used to get, in the Place de la Concorde in Paris, there is such a combination in the queenly city of the north gathered into so small a compass that it may fairly claim a chief place amongst the cities of Europe. Its old town with all its quaint buildings (where one might fancy oneself in Paris), and historic memories, the old Castle looming over all; the splendid new town with its grand architecture and the surrounding scenery, combine to make a place of which any people might well be proud. It holds a high place too in the opinion of horticulturists, as there are here many firms well known throughout the world—Lawson's, Dickson's, Downie & Laird's, and many others. Here again time was the enemy I had to contend with, and could only pay a hurried visit to the winter garden and nursery of the latter firm. These have already been described in the columns of the Journal, and I have only to add that I never saw Pansies and all the *Viola* genus in such numbers as I saw them in this nursery. Delphiniums, Pentstemons, and Phloxes, too, were in large quantities, for it is mainly for these despised florist flowers that Messrs. Downie & Laird are so famous, and I could only regret that my time was so hurried. Moreover, the season was rather too far advanced to see Pansies in their beauty; but we all know how very successful Messrs. Downie & Laird are in their culture, and how many fine varieties they are constantly introducing.

And thus finished my rambling notes of a most pleasant tour, in which I have endeavoured to note what may be interesting to my fellow gardeners, and to show them that with all their difficulties of climate, our brethren across the border are setting us a good example of what ought to be and may be done, and so *valets*.—D., Deal.

## TOMATOES AND THE POTATO DISEASE.

Your correspondent Mr. A. Boyle (page 305) is undoubtedly right in considering the disease of Potatoes and that of Tomatoes to be quite identical with each other. The Rev. M. J. Berkeley was the first to point out this fact many years ago, and I have repeatedly referred to the matter in my recent papers upon the Potato disease. The disease of the two plants is in every way the same. Mr. Moorman's suggestion (page 327) that other members of the *Solanum* family besides the two above mentioned may also suffer from the Potato disease, is also well known to be correct. Mr. Berkeley detected the fungus of the Potato disease upon the *Petunia*; it is also not unfrequent on *Solanum Dulcamara*.

Your practical readers will see at a glance that it is not necessary for Tomatoes to be in the neighbourhood of diseased Potatoes for them to take the disease. As both Potatoes and Tomatoes are liable to the same murrain, and as other members of the *Solanum* family are also liable to it (and at least two members of the *Scrophulariaceæ* are liable), it is only reasonable to suppose that all these plants become affected

with the disease direct and without any necessary intervention of the Potato as a nurse-plant.

Monkeys in their native haunts suffer from attacks of the same fevers as men; they suffer from consumption, catarrh, and from other diseases frequent in the human family, but it does not follow that monkeys must catch these diseases from men. The explanation is that both fall under the attacks of the same noxious infectious matter, whatever that matter may be. The noxious matter is carried in or by the air, by water, or the earth.—W. G. SMITH.

In answer to your correspondent Mr. J. W. Moorman, I have two rows of Tomatoes distant from each other against south walls and full of fine fruit destroyed this season after each row had ripened about one-half of its crop. The earliest lot, in the dampest situation of the two, was attacked first and ruined in about two days after showing signs of infection. The second lot on the more open and drier situation has not gone so fast, but is quite as surely affected. There are no Potatoes within a quarter of a mile of my garden, and very few, if any, within a greater distance.

In my opinion the wet autumn and not the proximity of Potatoes has caused the disease in this *Solanum*.—SOUTH DEVON.

### JUDGING VEGETABLES.

THIS is a subject which, like our worthy friend Mr. Taylor, I for one would like to see ventilated in the pages of the Journal. Mr. Taylor, writing on the subject on page 231, says that "Good judges of vegetables are extremely few, whilst those who may be called good judges hold very different views, and there is anything but consistency in their awards." I quite agree with Mr. Taylor in this and with his paper in general. I desire to see some agreement come to as to the way vegetables should be judged.

In my opinion Potatoes, Peas, and Cauliflowers ought to stand in the order of merit named in a collection of any number of varieties; and yet I have seen Tomatoes, Vegetable Marrows, and Cucumbers, and these of no merit, placed before superior examples of the other three. At a local show I asked one of the Judges how they could possibly arrive at such a conclusion as they did on the collections—throwing out a collection containing superior examples of Potatoes, Peas, and Cauliflowers (which collection, by the way, obtained "highly commended"), placing before it a collection in which Tomatoes, Vegetable Marrows, and Cucumbers were prominent. The reply was that the Potatoes, Peas, &c., were so easy to grow and so common, and that the others were high-class vegetables. My reply was, "These are also easily grown," and questioned if any one of them was of more value and importance on a gentleman's table than Potatoes. "No," was the reply, "but they are so common." Now, will anyone say that there is much reason in this line of argument? Because Potatoes are common and of the utmost importance and value to all, are they to be thrown overboard in collections along with two other of our best kinds of vegetables, and Tomatoes, Vegetable Marrows, and Cucumbers placed before them? I cannot consider that to be sound judgment. Will anyone look around at the present day and say if there is any one vegetable that is receiving the same amount of care and attention as the Potato? Does the International Potato Show, Alexandra Palace, not furnish a reply? I would ask the Tomato champions if there has been any such show held anywhere and such prizes offered for Tomatoes, Vegetable Marrows, and Cucumbers individually? I desire to see vegetables which are good and useful adjudged their proper value, but I fear the present fashion of judging vegetables has a tendency to defeat the purposes for which shows are held.

I should like to hear more on this subject from Mr. Taylor and others who are able to discuss it.—JAS. FAIRWEATHER, *Halston*.

### ACACIA LONGIFOLIA.

ACACIAS are amongst the easiest grown and brightest of hardwooded spring and summer-flowering plants. They are well adapted for cultivation in pots, where the plants flower profusely when in a small state, and they are equally suitable for planting-out in conservatories where they form large bushes or trees, which in early summer are laden with golden flowers, rendering them both elegant and bright.

The genus comprises an immense number of species, all of

which are more or less desirable stove and greenhouse decorative plants. The greenhouse species are the most generally useful and the most commonly cultivated, as the plants in pots can be grown out of doors in the summer months, where they require a minimum amount of care to preserve them in health, and when removed under glass they expand their thousands of flowers freely. For affording cut flowers Acacias are extremely useful as, especially when planted out, the plants may be cut to almost any extent, and, in fact, are benefited by the operation. A plant of the above-named species planted in the bed of a conservatory has yielded me armfuls of golden sprays, which have been valued for their slender elegance and cheerful colour. It is by no means the most handsome of the genus, yet of its usefulness I have had many proofs. Others of the most attractive of this large family which are especially worthy of culture are *armata*, which flowers freely even when only a few inches high, and may be forced into flower in mid-winter; *floribunda*, *grandis*, *dealbata*, *spectabilis*, *verticillata*, *Hugelii*, *falcata*, and *longissima*.

Fig. 50.—*Acacia longifolia*.

Plants are easily raised from cuttings, which mode is preferable if dwarf flowering plants are required, but seedlings grow more rapidly, and also flower freely if the shoots are well matured by exposure to the summer's sun. The plants grow freely in a mixture of loam and peat, and are seldom injured by insects.—J. W. B.

### THE ROSE ELECTION.

IT was with the greatest astonishment and indignation that I read the result of the poll, and I cannot help thinking many other exhibitors will feel the same. Until, however, we learn who the electors are we cannot form any true judgment as to the result, but from the names mentioned by Mr. Hinton I should say there was a very little wheat and a tremendous percentage of chaff. Now, this is not what we want in a Rose election which treats of exhibition sorts. What Mr. Hinton should aim at should be getting the opinion of the leading nurserymen and those amateurs alone who have distinguished themselves at the London or large provincial shows—not the opinions of anyone who may choose to send in a list. A more misleading list than that published as the result of the poll it has never been my lot to read.

Here, for example, we have *Gloire de Dijon* placed 23rd, and *Marie Van Houtte* 44th, and *Souvenir d'Elise* 38th. Shades of my ancestors, what a result! What a miserable, misleading, unrighteous, abominable (please Mr. Publisher choose a jolly bad

adjective) election. Why, Gloire de Dijon rarely if ever gives a bloom which is perfect in form, while Marie Van Houtte and Souvenir d'Elise are always grand. There is not a greater impostor out than Gloire de Dijon, and yet it is the first in the list of Tea Roses.

Next we have a most charming climbing Tea, Belle Lyonnaise, bracketed with that hulking coarse abomination Paul Neron. Belle Lyonnaise, a seedling of Gloire de Dijon, and as much superior as Catherine Mermet is to a common China Rose, and yet the lovely and youthful daughter is placed 54th on the list, and the mother—*passé* and *blasé*; fat, fair, and forty—23rd.

Call this an election? Why, it is no more the voice of the Rose world than the decision of a dozen clodhoppers in a village alehouse can be called the voice of the nation. Then among the Hybrid Perpetuals we have Dupuy Jamain placed 29th, and Duc de Rohan 71st; the former being a Rose which is as thin in substance and about as many petals as a Horse Daisy, the latter being a grand double Rose of splendid constitution, and which in the autumn is invaluable.

Thank goodness there are some redeeming points. We have (not so far at least) Madame Chirard named, or that other pet of the "ninety-and-nine" gentleman Baron Chaurand. But no doubt when the lists are published they will come to the front once more.

It is also news to me, for one, that Mr. Bennett introduced that gem of the purest water Madame Marie Cointet. O, Hercules, Hercules! what would I not give to see your face when you see that the Duke of Wellington is placed 39th, and Madame Charles Wood 40th; your two pets, *mon ami*, the latter, always the one you try to put at the corner of your back row, 39th in merit. Oh! hide your diminished head in your *Heavy-tree*, and next you set up a box of blooms take the result of the poll as a guide. Well, too well, did you foresee the result when you refused to send a list.

Then we have Céline Forestier placed 85th, and Maréchal Valliant 83rd, while Souvenir de la Malmaison—that Rose which is rarely if ever seen in anything but a 72 stand—placed 43rd. Beauty of Waltham again, that charming Rose which covers the very name of Paul with glory, which has not a fault, which will die before it shows an eye. This is—Where, gentlemen, do you think? Not 12th or even 24th, but 56th; not even in the 48. Burn your plants Messrs. Paul, strike out its name from your catalogues, no more quote her as the gift, the sweetest of gifts you have conferred on a thankless world, for your beauty is considered unworthy of a stand of 48.—WYLD SAVAGE.

[In earlier elections we have talked over the possibility of a competitive examination for voters. Perhaps "WYLD SAVAGE" would kindly give us a plan by which we might eliminate the voters that know nothing about the matter and that have managed to make such a hash of the present election. Had he (for such a letter cannot emanate from one of the tender sex) signed his name we might have discovered if he were an elector, and might have taken counsel and a lesson for the future in paying attention to his list.

"WYLD SAVAGE" starts in error. Nothing whatever has been said about best "exhibition" Roses, but merely best Roses. It is true that a great many of our best Roses are also our best exhibition Roses; but not a few of us may think highly, for instance, of that "impostor" Gloire de Dijon (glorious old Rose! fancy anybody calling you an "impostor!"), even though it does not often give us an exhibition bloom; yet that it does this sometimes the previous pages of this Journal would prove, for I recollect well a remark in the report of one of the large shows, that the best bloom in the exhibition was one of Gloire de Dijon! Marie Van Houtte may be "always grand" with "WYLD SAVAGE," it is never so with me. It is lovely, beautiful, exquisite, *charmante*, I grant, but grand—a grand exhibition Rose never, at least with me. This makes me think that our friend "WYLD SAVAGE" can know nothing of our sweet Wiltshire spring breezes, but must enjoy the balmy south. I can understand Dupuy Jamain's position as compared with Duc de Rohan, at least in this part of the country. His description of the former does not agree with ours. It might have a few more petals, but even Charles Lefebvre would be improved by a few more, but Dupuy Jamain is hardy and has a colour specially its own. Duc de Rohan I allow is grand, but is here very delicate.

If the giants have not sent lists—if Hercules and others decline to assist, that is a matter which we all regret, none more so than the returning officer; but with all due deference to "WYLD SAVAGE," that cannot make the result deserve such

a sweeping censure as "a more misleading list than that published as the result of the poll it has never been my lot to read." If there are no good Roses, even judged by "WYLD SAVAGE" as "exhibition" Roses in the first fifty, I for one do not know where to look for good Roses. Are the best Roses to be found outside the fifty if the list is so misleading? I trow not. Certainly there are many, very many, good Roses still outside the fifty, but the best are inside the charmed circle; and when such good rosarians as Messrs. Cant, Cranston, Camm, Curtis, Peach, Prince, G. Paul, and Turner in their lists name something about two-thirds of the fifty, the result cannot be so very "misleading" as "WYLD SAVAGE" would make it out. I can only in charity suppose that "WYLD SAVAGE" did not read the explanatory heading of the table, or, however keenly he might have felt the insult to some of his pets, he could not have so thoroughly acted out the character of his *nom de plume* as to write sneeringly of any effort, however humble, to attach the raisers' names to the Roses. This suggestion of Mr. Peach's was, I think, a very interesting addition; to him is due the credit, and to him, Mr. Radclyffe, and all who have assisted this portion I feel deeply grateful; but in the heading to the table I acknowledged the imperfections of this portion, and how grateful I should feel to anyone for help. Surely the kind and courteous way would have been to have communicated with me on the subject of Marie Cointet for instance. I am now able to correct that error by giving the credit of raising that beautiful Rose to Guillot, fils.

No one ever supposed that the result of the election would be perfect; not even the savage writer could have had an idea so wild. It is simply approximative. That it is of some value, and looked forward to with interest, and a fair guide, public and private acknowledgments attest, and I am content to leave it to general judgment.—JOSEPH HINTON, *Warminster*.

R.S.—Lest the vials of wrath should be poured out on myself, I may state that though my list is headed Gloire de Dijon it is not a list in order of merit, and the position is accidental. I am not ashamed of still placing that old Rose in the first twenty. I confess that in that division he is low down, but of his place now I am not ashamed, neither have I any need to be, supported as I am by the following gentlemen, whose knowledge of and intimate acquaintance with Roses is greater probably than that of "WYLD SAVAGE"—viz., the Revs. Dombrian and Peach, and Messrs. Turner, Davison, Walters, Ramsey, and George Paul, in whose company I am well content to be. Were I forced to begin in order of merit—not a bad plan—I might shock "WYLD SAVAGE," and be very exceptional by placing Pierre Notting at the head, that Rose having given me grander blooms, I fancy, than any other.—J. H.]

#### HINTS ON HOME ADORNMENT.

I NOTE that you have had inquiries concerning the drying of autumn leaves. As this subject is referred to under the above heading in an April number of the *New York Tribune*, I send what I extracted from that paper, thinking that it may be acceptable to your readers at this period of the year.

"In preparing autumn leaves, I have found that when varnished or oiled they seem more liable to catch the floating particles of dust; ironing them in any quantity is laborious, and I think gives them a less natural look; while if laid in books (books not wanted for every day's reading or reference), and left in press undisturbed a few weeks, the result will be entirely satisfactory. A special word as to Ferns. These should be placed very carefully in press as soon as possible after gathering, and allowed to remain there until wanted for use. These always require delicate handling, as they are very brittle and easily spoiled. Do not omit the little things you find about home in your walks or rides; gather bunches of green Oats and Rye, the feathery Grasses, the late bronzed leaves of the Blackberry and perpetual Rose, and even the despised weeds, and to these add some green leaves of Ivy, Maple, or any convenient sort by way of contrast, and you will find yourself amply repaid for your trouble by the additional airiness and grace given to your bouquets. When the dark and stormy days of winter come get together your treasures, and with a bottle of mucilage, pasteboard cut into various shapes for backgrounds, a strong needle and thread, by the exercise of your artistic taste in arranging and making-up of your adornments, you will find a pleasant occupation, and be enabled to brighten up your rooms to the admiration and enjoyment of all your household.

"I do not know that I can give you any better ideas for the arrangement of your leaves than by describing my parlours. On entering the front room the first thing that strikes the eye is a group composed of two crescent-shaped pieces running into each other, formed of the deeply indented brown Oak leaves, mingled with various coloured leaves and Ferns, and dried Oats and Grasses fastened in here and there by a drop of mucilage, the ends terminating with long Ferns or sprays of Sumach. Between the front windows is a differently shaped cluster with plenty of large Ferns forming the outline and filled up with a diversity of leaves. In my rambles in autumn I secured some long branches of the Briar-wood Vine bearing full bunches of dark purple, almost black berries; these draped in tangled masses thickly intermingled with the berries of the Bitter-sweet Vine, and Star-oak burrs are trained along the cords over a picture in the opposite end of the room, and also over a favourite little chromo which hangs in a recess above a stand of Tradescantia, that most satisfactory plant which grows so luxuriantly in spite of stove heat and illuminating gas. Around the cords of another picture is trained a long spray of wild Clematis, with its feathery seed pods, looking as if a breath would blow them away, while in reality they make a permanent decoration.

"Over a crimson bracket supporting one of Rogers' statues is a large half wreath composed entirely of Ferns in variety, as green and fresh as when in their native haunts, and on a dark carved corner bracket stands a slender white vase of Ferns and Sumach, while from the base of the bracket floats the grey Florida Moss, so soft and filmy, interspersed with our crimson northern berries. For the mantel I have a small vase of Ferns with a delicate butterfly hovering on it, and a pair of panel pictures. 'Ah! but those are painted,' is the exclamation of visitors. No, they are not painted, they are nature itself. Not having the gift of painting, and determining not to be outdone, I again drew upon leafy treasures. I procured two thoroughly-dried boards of the desired size, and had them painted black, sandstoned, and varnished. I then selected the tiniest, brightest, and most perfect leaves and Ferns, and arranged them in groups upon my panels, attaching them carefully with mucilage, then covered them with glass the exact size of the boards; the edges were bound together with narrow strips of black paper, such as is used by bookbinders.

"My crowning attraction is our window, the admiration of all beholders. It opens into a small library with a glass roof, which admits light sufficient to make it as lovely by day as by night with a strong gaslight behind it. I procured from the stationers a piece of oiled tracing muslin the exact size of the individual panes, and filling the lower half of the window, which consists of two large panes of plate glass, the muslin giving the appearance of ground glass. In one pane I have a border of Ferns, in the centre a bunch of Ferns with a few coloured leaves and delicate sprays of Grass. In the other is a large bouquet of exquisite leaves of every shade intermixed with Ferns, Grasses, and Oats, surrounded by a half wreath of Ferns and green leaves, terminating on each end half way down the picture with a leaf of the long pointed walking Fern, and the whole is a marvel of beauty. This window is not only a picture to all but it is a memory and a token of friendship. I have a dozen varieties of Ferns, and some of these are joyous reminders of pleasant friends found among the mountains. Some are a tribute of affection gathered by a friend, while those curiously-spotted Maple leaves and other brilliant beauties came from the granite hills of New Hampshire, and the remainder from different portions of New Jersey."—E.

### MERITS OF MELONS.

CAREFUL attention is required to produce a good crop of Melons, for unless the necessary requirements of the plants are provided failure in some form is sure to be the result.

My intention, however, is not to treat on the culture of the Melon so much as to give the result of my experience respecting the merits of the varieties I have grown this season. I have grown two crops consisting of varieties which I will name. The first to ripen was Haddo House, green-flesh, a variety which was placed first at the Dundee International Show, and I was as pleased to hear of its taking the first prize for Green-fleshed as "D., Deal," was to hear of Little Heath gaining first honours for Scarlet-fleshed Melons. Haddo House is a variety which was grown where I served my apprenticeship, and with which my superior used always to carry off the first prize against all competitors. Some fruits might

have surpassed Haddo House in size, beauty, and colour, but when the judges came to taste the sweets of each they invariably awarded it the first place, and since then I have always grown it, and it was my first ripe this year amongst seven other varieties; and where three crops of Melons are required in the season it is an excellent variety, being a free setter, matures quickly, and has a good constitution.

Next in order of ripening is Little Heath, scarlet-flesh, which I consider a first-class variety of easy culture, the fruit having a good flavour and the plant a strong constitution. I sent my last three Melons of it in for dessert on October 9th. Hero of Bath (Sutton's) is an excellent scarlet-fleshed Melon. It is not of large size, but is first-class in flavour, handsomely netted, and a free setter. Malvern Hall I find a very good scarlet-fleshed Melon; it is not large, but a very fine setter, and the foliage is not so large as some of the varieties, which makes it a suitable variety for frame-culture, where it succeeds remarkably well, never showing any signs of cracking.

I have grown A. F. Barron (Gilbert's) this season, and it is certainly a very superior green-fleshed Melon, remarkably thin in the skin and deep in the flesh, and of excellent flavour; but it has one drawback where three crops are required in the season, on account of the length of time it takes to ripen, being at least three weeks later than the other varieties I have grown this season. Empress Eugénie is a good scarlet-fleshed Melon, and grows to a large size, and is suitable for either house or dung frame, being a free setter and hardy constitution. Prince of Wales is a free-fruited variety of noble appearance, and attains a large size. Bloxholm Hall is also an excellent Melon, beautifully netted, and of first-class flavour. I have also a seedling scarlet-fleshed Melon which I have raised, which is very much liked by all who have tasted it here; it has a robust constitution, and is very suitable for house-culture, being a free setter, and attains a large size; and another desirable quality in its favour is that it will keep for six weeks or more if cut a little before it is quite ripe and stored in some cool place, but before using placing it in a heated house a day or two, which improves the flavour. I have fruits now which have been cut a month, and they look as if they would keep much longer—a very desirable quality in a Melon, considering it is the only way we can prolong the season of Melons. Good Cucumbers can be grown in winter, but good-flavoured Melons cannot be grown during the absence of sun.

The great point to secure in keeping Melons is a very cool place. I remember an experiment that the gardener tried at a place where I had some good lessons in gardening. We happened to have several Melons ripe, and the family was not expected home for some weeks, and the gardener was anxious to keep them if possible until they came, so we packed them in boxes and placed them in the ice house; but unfortunately the ice melted at the sides and the boxes slipped down and most of the Melons were smashed, but what remained were as fresh as when they were cut, showing that it was possible to keep them in that way.

I often hear complaints of Melon plants cankering at the collar, the result no doubt of careless watering. In order to prevent that I always have the collar of each plant surrounded with a mixture of lime and charcoal dust, a small heap being placed well up the stem of the plant, and anyone trying this will not be troubled with canker at the collar.—J. ANDERSON, Hill Grove.

### EARLY WRITERS ON ENGLISH GARDENING.

No. 20.

REV. WILLIAM MASON.

THE REV. WILLIAM MASON, Precentor and one of the Residentiaries of York Cathedral, Prebendary of Driffild, and Rector of Aston; was author of "Elfrida," "Caractacus," "The English Garden," "Translation of Fresnoy's Art of Painting," and several other celebrated poems, the Life of Gray, &c. He was born in 1725, the son of a clergyman, vicar of Holy Trinity, Hull. He was admitted of St. John's College, Cambridge, where he proceeded B.A. 1745; and whence he removed to Pembroke Hall, of which Society he was elected a Fellow 1747, and took the degree of M.A. 1749. In 1754 he entered into holy orders, and was patronised by the then Earl of Holderness, who obtained for him the appointment of chaplain to His Majesty George III., and gave him the valuable rectory of Aston. Mr. Mason was an acknowledged scholar, and possessed high claims to a considerable degree of poetical reputation. The memorable "Heroic Epistle to Sir William Chambers" has been often attributed to this gentleman; and,

if he were the author of it, he certainly possessed no small portion of satirical humour as well as poetical strength; but the work is so different from the general character of his productions, that it is hardly to be considered as the offspring of his mind. It is certain that he never acknowledged it. In private life his character, though with something in his manners beyond the mere dignity of conscious talents and literature, was distinguished by philanthropy and fervid friendship. For the latter quality we have only to observe his conduct in relation to Gray, whose genius he estimated with a zeal of enthusiasm, to borrow an expression of old Theobald, "amounting to idolatry." Upon the whole, he is to be viewed as a man who may be ranked with the supporters of British literature and morals.

Fig. 51.—Rev. William Mason.

He died April the 5th, 1797. He had survived his wife thirty years, but remained a widower, and always spoke of her with the tenderness expressed in these lines, which he inscribed to her memory at Bristol, where she died of consumption.

"Who'er like me with trembling anguish brings  
His heart's best treasure to fair Bristol's springs;  
Who'er like me, to soothe the disease and pain,  
Shall pour those salutary springs in vain:  
Condemn'd, like me, to hear the faint reply,  
To mark the fading cheek, the sinking eye;  
From the chill brow to wipe the damps of death,  
And watch in dumb despair the short'ning breath:  
If chance directs him to this artless line,  
Let the sad mourner know his pangs were mine.  
Ordain'd to lose the partner of my breast,  
Whose virtue warm'd me, and whose beauty blest;  
Fram'd every tie that binds the soul to prove  
Her duty friendship, and her friendship love.  
But yet, rememb'ring thus the parting sigh  
Appoints the just to slumber, not to die;  
The starting tear I check'd, I kiss'd the rod,  
And not to earth resign'd her, but to God."

He died at Aston, and in the church is a marble tablet with a profile bust, erected to his memory by his successor, the Rev. C. Alderson; and on the ceiling of a summer-house in the rectory garden is an embossed medallion containing the profiles of himself and his friend and brother poet Gray.

The garden and the ground around it were laid out and continually improved by Mr. Mason. Gardening was the favoured employment of his leisure, and even in his private letters there are almost always references to it. Some are all in verse. The following is a specimen. Writing of the owner of a superior garden he said—

"Smiling he spake, nor did the Fates withstand;  
In rural arts the peaceful moments find;  
Say, lovely lawn, that felt his forming hand,  
How soon thy surface shone with verdure new;  
How soon obedient Flora brought her store,  
And o'er thy breast a shower of fragrance hung.  
Verdure came; his earliest blooms he bore,  
And thy rich sides with waving purple hung."

"The English Garden," the longest of his miscellaneous

poems, entitles him to a place in these columns. It is practical, though chiefly directed to aid ornamental gardening.

"To trace the path, to form the fence,  
To mark the destin'd limits of the lawn."

He warns against planting too many Conifers; rather "select the shrubs patient of the knife," such as the Laurel, &c. Recommends a well-watered locality; and that in all plans the aim should be simplicity, and "the curve that Nature loves."

## VIOLETS AND PANSIES.

I WAS very much pleased with Mr. Beachey's letter on Violet odorata pendula of New York, and commonly called New York. It is certainly a most valuable variety, and is, without doubt, the best double ever yet sent out. Mr. Beachey enumerates many of its good qualities, but it yet possesses another in not being at all subject to the attacks of red spider. It is certainly the hardiest, the freest blooming, and one of the most fragrant of double Violets, and of its beauty there can scarcely be two opinions.

There are also several other double Violets which I think deserve to be better known than they are. One named Blandiana is a very handsome one, its colour being deep purple, distinctly striped with bright rose. It is very fragrant, and a good winter bloomer under glass. Reine Louise and Marie Louise are both, I think, better whites than The Queen. The foliage of Reine Louise is much handsomer than is that of The Queen, whilst Marie Louise generally has beautiful golden variegated foliage in the spring. The other doubles are, I think, pretty well known.

In singles Victoria Regina is the largest and finest yet introduced, although I think a seedling of my own, Beauty of Louth, is a worthy companion to and very distinct from it. It is a light blue with a white eye, very bright in colour. It ought, however, to make the best of it, to be grown in a cold frame, as, indeed, all Violets ought, at any rate as far north as this. Another fine single but little known is Wilsoni—I believe an American introduction, very fragrant and very handsome, but rather delicate for outdoor growth. Its colour is pale blue with white eye, but it is not so good a shaped flower as Beauty of Louth, having more pointed petals. It is a capital winter bloomer in a frame.

I now mention how surprised I have been never to have seen any mention made of a fancy Pansy called Gaiety, raised by Messrs. Cocker. It is the most brilliant in colour of any I ever saw, being something like James White, but a great improvement. Its mixture of brown, crimson purple, chestnut brown, and yellow is strikingly handsome; it is also very good in shape, size, and substance, and a very good grower and bloomer. Duchess of Edinburgh (Cocker) is also first-class. —GEORGE W. BOOTHBY, *Louth*.

## A PICTURESQUE GARDEN.

SUSSEX is a picturesque county, boldly undulated, rich in beautiful scenery, abounding with curious nooks and corners, rocky ravines, steep banks clothed with Holly, Fern, and Heather, and many other features—wild, quaint, and uncommon—affording such facilities for the formation of picturesque gardens as are very rarely to be met with. The numerous new places that are springing up in this county afford ample proof how highly these great natural advantages have at length come to be estimated. It is not, however, to new gardens or the doings therein that I now wish to call attention, but to one that is comparatively old, so old in fact as to afford most valuable hints to those who in the designs of their new gardens very wisely follow no beaten track, no set form, but rather adapt their plans to local peculiarities of climate and the physical formation of the land.

A wide dell, its upper end an irregular semicircle, shut in by steep banks, clustering timber trees, and high masses of rock, its lower end opening out upon the grassy undulations of a park and the bright waters of a lake of considerable size. The sides of the dell present no formal lines, but a pleasing irregularity of steep declivities and gentle slopes, hid at some parts by dense growths of evergreens and at others perfectly open, with fine old trees of Chestnut and Oak high up on the slopes, forming a sort of enclosing boundary, the huge old pendant branches of some sweeping down to the turf and forming a charming background to the shrubs and plants grouped below them. A narrow bank with a roadway at the top, fringed with a thick margin of St. John's-wort, intersects the dell, dividing

it into two parts, which are connected by an archway piercing the centre of the bank, its sides being clothed with Ivy, Ferns, and Mosses. The sides of the bank, too, bear large masses of rock interspersed with a rich collection of choice Ferns; not just a single specimen or two of each kind, but a profusion of rare gems absolutely rampant with health and vigour, and of which haply you and I, my readers, can boast of but a few small plants, and those so precious as to be cherished in pots.

Advantage has been taken of this division of the dell into two portions to impart a different character to each. This has been done so skilfully and with such admirable taste as to preserve the unity of the whole, no incongruous feature presenting itself at any point. On one hand we have masses of rock boldly grouped in irregular but most picturesque order, and so disposed as to form ledges, nooks, or open "mountain slopes" to suit the requirements of Alpine plants. Little rills and pools of water for aquatics, intermingled with Rhododendrons and other shrubs of the evergreen class, the whole relieved by a few well-chosen, well-placed Conifers, all in admirable keeping with the natural surroundings of projecting rocky strata and high turf-clad slopes which sweep from the rocks under lofty Chestnut trees to the lower part of the dell, where on the other hand we find Rhododendrons in much greater abundance disposed in continuous belts with detached groups, alternating with others of Azaleas, Kalmias, and Ferns upon turf, with a walk winding along the bottom of the dell onwards to the lake. An arbour placed high up upon one of the slopes under the trees commands a view of the chief features of this lower part, thus affording the combined advantages of quiet seclusion, the cool shade of lofty trees, and bright glimpses of some of the most beautiful objects in nature.

Such are the general features of the rock garden of J. H. Selater, Esq., Newick Park, near Lewes. It is a veritable "charming little valley," replete with treasures rich and rare, as we find upon the closer inspection that involuntarily follows the first delighted glance. An interesting garden? Well, I had often heard the term, often used it myself, but never previous to my visit to Newick had I realised its full meaning. It was my good fortune to go through the garden with Mr. Selater, and he very kindly pointed out many of its most attractive features. Almost every plant has a history, and this imparts to them an intrinsic worth and an interest that can never attach itself to ordinary collections. Many an alpine gem has been gathered from its native habitat and brought here to be cherished and cared for by Mr. Selater's own hands. In a rocky nook carefully made to resemble its wild haunt was a fine tuft of the Mountain Parsley Fern (*Allosorus crispus*). On a damp sheltered rocky ledge overhanging a pool of water *Trichomanes radicans* was being established, a covering bell-glass being used as much to ward off the attacks of snails as to retain moisture.

The largest mass of *Hymenophyllum tunbridgense* that I have ever seen was flourishing with extraordinary vigour upon the sloping face of a sandstone rock, part of a strata protruding from the upper end of the dell, a piece of water which supplies a cascade being above and behind it; so that while the face of the rock is fully exposed to the air, yet it is kept constantly moist by the water behind, which undoubtedly accounts for the rampant growth of this rare Filmy Fern. But it is not alone; other plants and Ferns are so abundant on all sides, and so fine withal, that one is puzzled which to select for notice. The Royal Osmunda, the curious Hay-scented Buckler Fern (*Lastrea fenestricii*), Oak and Beech Ferns, Shield Ferns, and Hart's-tongue, the last two species in numerous varieties, are all here arranged in no formal order, but meeting one at every turn, and this I think gives to the place its greatest charm. The guise in which the plants present themselves to us is so natural that we can do nothing but admire and strive to learn how it is done—not an easy lesson, for as we look a conviction steals upon us that skill and taste of no mean order must have been brought to bear upon a work that has been wrought to so successful an issue.

At more than one place here there are quantities of the Falkland Islands Fern, *Lomaria magellanica*, introduced into this country upwards of thirty years ago, and still uncommon, at least as a hardy Fern, and yet it is one of the most ornamental and striking sorts that we have. Its noble deep green fronds, some 2 feet in length and with rich pink stems, have an aspect of dignity and grace that is in fine keeping with the massive grandeur of the huge sandstone rocks, to the base of which they form a most fitting fringe.

The seedling *Osmundas* clinging to the face of the rock upon

which the spores are blown afforded another curious and interesting sight. Much of the rock is also draped with trailing growth of the pretty little *Linaria Cymbalaria*, and the equally pretty Cornish Figwort (*Sibthorpia europæa*), which at some places has trailed downwards to the foot of the rocks and spread out upon the ground, forming the most charming cushions of soft green foliage imaginable. A host of noble specimens claim the notice which I may not give them without extending this paper to an undue length. There was *Adiantum pedatum* established in its present situation for several years, and finer than I had before seen it; *Woodwardia radicans* in a large bold clump, perfectly healthy, but not so large as we sometimes see it under pot culture; *Struthiopteris germanica* in immense quantities, one circular mound being planted with matched plants of it arranged in circles—the only bit of formal planting in the garden, but for which the handsome form and precise growth of this choice Fern was admirably adapted. *Osmunda regalis* was also most abundant, the effect of one bold clump of it containing some dozens of huge plants in front of a semicircle of Rhododendrons, with a background of tall trees, was especially fine. But what will the lovers of Ferns say when I tell them of a bed of *Onoclea sensibilis* some 15 yards wide by as much long? This bed has probably no equal in this country, and is quite sufficient in itself to form the boast of any place, but here it simply ranks as one of many marvels.—EDWARD LUCKHURST.

### ASPARAGUS.

It seems curious that this highly esteemed vegetable, ranking in its season as highly as the Pea or the Cauliflower, should in so many gardens be merely an apology for what it might be, and even as it is produced by French and English market gardeners. Notwithstanding the amount of care devoted to its cultivation, it is doubtful if some highly important points are not generally neglected. It is with Asparagus as with many another cultivated plant, someone has been successful by following a particular mode of culture, and, as sheep follow their leader, everybody must follow suit.

A good depth of soil is of much importance—say at least 3 feet deep, but good Asparagus is obtainable off land less than half that depth. In the one case the crop will fail in yielding good returns long before the other is exhausted, and frequent making of fresh plantations will be necessary to keep up continued supplies. In most gardens it would be a good plan to plant a little yearly, or once in two years, in order to have a continuous supply of strong growths to cut; for in the great majority of gardens plantations three to six or eight years of age will yield the best crops; and as things go at present, where most of the ground is cropped and double cropped without intermission, relying merely on young plantations of Asparagus will pay better than allowing them to exhaust the soil too much. Being a deep rooter, it is necessary to stir the ground as deeply as possible; but if the subsoil is of a poor nature on no account should it be brought to the surface. In trenching the ground, merely dig the bottom of the trench over, working plenty of cow manure in, or, what would be of more lasting benefit, adding any thoroughly decayed rubbish or soil that can be had.

Where ground can be spared and time be had to prepare the soil, seedlings sown in April in a rich bed, and transplanted the same summer, may be expected to do best; but in the majority of gardens the better plan will be to allow the plants to remain twelve months in the seed bed, or from April to the April following, when there will have been time to prepare the ground thoroughly during the previous autumn or winter, whilst there will be but little lost in the cropping. When the plants have grown an inch or two above ground, and on a dull day, planting should be performed; one man may be lifting the plants carefully with a fork, at the same time shaking the soil free from the roots; other two men will be engaged taking out shallow pits for the plants, leaving them cone-shaped in the centre, and again filling up the holes after the plants have been placed in position by another man set apart for that purpose. They may be planted 4 feet from row to row, and half that distance between each plant, which, however, may be increased to the same distance when the plants have attained to full growth. The plants must be well firmed by treading, and the ground pointed as the work proceeds; a mulching of rich manure will be of great advantage. They will require staking as soon as growth commences, using stout sticks, or a string or preferably a galvanised wire, may be stretched the length of

the rows and the shoots tied thereto as growth progresses. Staking the plants is of the first importance in many localities where summer and autumn gales prevail. The mischief the wind does if the plants are not secured cannot be over-estimated, as the stronger the growth the more are the plants blown about, quantities of shoots being entirely twisted out of their sockets and blown about the garden. Whenever such gales are prevalent, staking is simply necessary, or some other means of securing the plants, in order to keep them in vigorous bearing. If all goes well robust shoots will be produced towards the autumn, and all should be preserved in a growing state as long as possible. Successional crops of Cauliflower may be taken off from between the rows; French Beans or other crops may be also grown.

A surface dressing 2 or 3 inches thick of manure from the cow houses or mixed with stable dung, may be laid over the ground after the stems have been cleared away; enough loam or refuse soil to cover all should be placed over the dung, especially when the latter would be unsightly if uncovered. It is advisable not to cover the crowns of the plants with the dung. We prefer allowing the dung to remain on the ground entirely, as it acts as a mulch during summer, even if no better result is obtainable from it. The second year great care should be taken to secure all the shoots from being twisted off by the wind. If all goes well with this season's growth a few heads may be gathered the following spring, but if care is not taken to secure good growths it will be better to give the plants another year. In any case most of the gatherings ought to be taken from the extra plants, which will require removing the third or fourth year after planting, to allow space for the permanent plants to develop; or another use may be made of these supernumeraries where forcing is carried on, and that is to use them up for early supplies. Spinach, Lettuces, or Turnips may be grown between the rows the second season, but afterwards the whole ground should be devoted to the Asparagus only. No digging should be allowed amongst the plants after they are established; and should signs of exhaustion appear, some of the surface soil should be removed, and a mixture of fresh loam and dung placed over the entire surface.—R. P. B. (in *The Gardener*.)

#### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*SERAPIAS PAPILIONACEO-LINGUA*. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—“This very rare remarkable terrestrial Orchid is presumed to be a natural hybrid between *Serapias lingua*, *Linn.*, and *Orchis papilionacea*, *Linn.*, having been found in considerable abundance growing in company with those plants, and with *Serapias longipetala*, *Poll* (a species closely allied to *S. lingua*). This hybrid was first found near Genoa, and subsequently at Berre near Nice, and other places on the Riviera, as well as near Trieste and Lucca, and there are herbarian specimens at Kew from the department of Gers in France.”—(*Bot. Mag.*, t. 6255.)

*OXALIS ENNEAPHYLLA*. *Nat. ord.*, Geraniaceæ. *Linn.*, Decandria Pentagynia.—“In the ‘Flora Antarctica’ Dr. Hooker described this plant as the pride of the Falkland Islands, where it grows in such profusion at Berkeley Sound, on banks overhanging the sea, as to cover them with a mantle of snowy white in the spring month of November; adding that it is an excellent antiscorbutic and agreeable pot herb, though too acid to be used except in tarts and puddings. When the above was written this plant was supposed to be confined to the Falkland Islands; it was, however, found in the Straits of Magellan by D’Urville’s expedition, and by Lechler at Cape Negro, also in the Straits.”—(*Ibid.*, t. 6256.)

*LAURENTIA CARNOsula*. *Nat. ord.*, Campanulaceæ. *Linn.*, Pentandria Monogynia.—“A very elegant little annual, native of muddy places in Sierra and Indian valleys in California, and thence, north-eastward, to Wyoming territory (A. Grey). It is remarkable as being the only American example of the genus *Laurentia*, of which ten species are known, the rest being natives of South Africa and the Mediterranean region. The cultivated specimens differ widely from the native in habit and appearance, the native ones being shorter, with very succulent and indeed thickened stems, and having flowers not one-quarter the size of the cultivated ones. *L. carnosula* was raised from Californian seed by Mr. Thompson of Ipswich, who flowered the specimen here figured in July, 1875.”—(*Ibid.*, t. 6257.)

*MASDEVALLIA POLYSTICTA*. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—“Imported from Peru by Mr. Ortgies of the Botanic Gardens of Zurich; native of the temperate

region of the Andes in Northern Peru, and discovered by Mr. Roezl.”—(*Ibid.*, t. 6258.)

*CALLIPHURIA HARTWEGIANA*. *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia.—“It was discovered by Hartweg about 1842 amongst the mountains of the province of Bogota in New Grenada, and has lately been imported by Mr. William Bull, from one of whose specimens the present figure was made in July, 1874.”—(*Ibid.*, t. 6259.)

*ICACINA MANNII*. *Nat. ord.*, Olacineæ.—“A native of the Gulf of Guinea, where it was discovered at Old Calabar by Mr. Gustav Mann (now inspector of indiarubber forests in Assam), when collecting for the Royal Gardens in 1863; he, however, sent no living specimens. In 1865 its large tuberous roots were sent by the Rev. Mr. Thompson to Mr. Clark of the Glasgow Botanical Garden, which flowered in October, 1870.”—(*Ibid.*, t. 6260.)

*APPLE*.—*Redleaf Russet*.—“This Apple was raised from seed by Mr. Cox of Redleaf, who thus speaks of it:—‘The Redleaf Russet is ostensibly, according to my own manipulation, a cross between the Golden Knob and the Golden Harvey, but there is a possibility that I was anticipated by the bees, as a tree of the Old Nonpareil grew near by; and I am the more confirmed in this because the fruit possesses three of the characteristics of the Old Nonpareil—namely, the shape, the long stalk, and the tenderness of flesh. The colour of the skin is that of its parent, the Golden Knob. The yellow colour of the flesh would seem to be derived from the Golden Harvey, while the growth of the tree and manner of bearing resemble both Old Nonpareil and Golden Harvey more than the Golden Knob. When in perfection the flavour is most delicious and peculiar to itself, and it may be considered in perfection from February till the end of May, after which, although keeping sound till the end of July, the flavour gradually deteriorates.’”—(*Florist and Pomologist*, 3 s., ix., 229.)

#### NOTES AND GLEANINGS.

MR. CHARLES TURNER, Slough, has forwarded to us blooms of a new *DAHLIA* named *Artist*, which opened too late for the autumn shows. It is a very gay and striking flower, and likely to be effective in the exhibition stand, and especially so for garden decoration. The flower is full, firm, and symmetrical; the colour is yellow, irregularly flaked with crimson lake deepening to the centre. The flowers in size and shape are similar to those of *Leah*, and, like that useful *Dahlia*, *Artist* has strong stems supporting the blooms well above the foliage.

—A CORRESPONDENT sends us the following note:—“The solicitude evinced by Messrs. Sutton & Sons of Reading for the welfare of their numerous *employés* is proverbial. Some time ago an establishment named the ‘British Workman’ was opened by the firm, and recently they have erected a TEMPERANCE CAFE and RESTAURANT contiguous to their premises for the use of their dependants and the public generally, and which it is hoped will possess attractions which will substantially promote habits of temperance, and provide the means for social intercourse, which too often can only be found in inns and taverns. This valuable contribution to the cause of temperance is deserving of patronage and success.”

—THE objects of the PELARGONIUM SOCIETY are:—1, To promote the improvement of the various sections of the *Pelargonium*; 2, To facilitate the introduction of new species and varieties; 3, To give system and method generally to the practice of hybridisation. These objects it proposes to accomplish by offering prizes, as liberal as the support accorded to it may permit, to be competed for by British and foreign exhibitors; by determining the merits and distinctive qualities of new varieties, and their suitability for conservatory decoration, or bedding-out purposes, or both; by cultivating all obtainable new varieties, British and foreign, side by side, and in conjunction with approved old kinds—during the first year under glass, and in the second year out of doors, facilities for accomplishing which, it is hoped, may be afforded by the Royal Horticultural Society at Chiswick; by the formation of a register in which approved sorts shall be entered and from which inferior varieties shall be eliminated; and by facilitating intercourse and interchange of opinion between raisers and cultivators. The qualification of membership is an annual subscription of one guinea paid in advance.

—We have recently seen how valuable as a bedding plant is the new *AGERATUM* COUNTESS OF STAIR, which has been favourably mentioned by the Rev. Mr. Peach. This *Ageratum*

continues to produce its dense trusses most freely, and plants of it potted from the garden cannot fail to be effective in the greenhouse and conservatory for a period of several weeks to come. No plants lift more safely than *Ageratums*, for if potted even when in full flower the plants seldom lose a leaf if properly attended to. In a week or ten days after having been potted liquid manure should be given freely, and the plants will then continue flowering all through the winter.

SOME exceedingly effective *BOUQUETS* are always to be found in the Central Avenue of Covent Garden Market. We noticed recently one which, though formal, was very striking. A white *Camellia* formed the centre, and from this to the outer edge of the bouquet were six rows at equal distances apart of single pips of *Stephanotis* flowers—six pips in each row—the angles being filled with *Violets*, and the whole edged with *Maidenhair Fern*. Other bouquets were made principally of *Camellias*, *Roses*, and *Eucharises*, with sprays of white and scarlet *Bouvardias* slightly elevated above the more massive flowers. This arrangement was very chaste and pleasing.

As a proof of the *MILDNESS* OF THE SEASON *Alternantheras* in the London parks have continued to put forth fresh leaves freely up to the present time, and these, especially in the case of *A. amona*, are of the most brilliant colour, proving that not only heat but moisture is necessary for these highly coloured "carpet plants" to appear in their richest garb. Tender though *Alternantheras* are, their beauty is retained longer than that of the *Golden Feather*, the foliage of which decays with extreme wet when the plants are planted closely together.

*MESSES. SUTTON & SONS* have issued their list of prizes to be awarded at their Root Show in November.

A SOCIETY of practical gardeners and others has been formed under the title of "The Bromley Common and District Horticultural Society." Its object is the improvement of gardening among all classes in the neighbourhood. Mr. J. Hobbs, The Fernery, Bromley Common, may be applied to for particulars.

In consequence of the extreme drought of summer being succeeded by a warm and moist autumn *VIOLETS* are in many places flowering almost as freely as in spring. One of the finest and sweetest is the variety recently raised by Mr. G. Lee of Clevedon and named *Prince Consort*. The flower of this variety is large, very round, pale blue, on a long stalk which raises it above the foliage, and is very fragrant. Flowers of *Prince Consort* were gathered for the market on the 8th of September.

*M. LEMOINE* has raised a *DOUBLE-FLOWERED LILAC*, which he has named *Syringa hyacinthiflora flore-pleno*. He applied pollen of one variety upon a hundred flowers of another, obtaining in the first instance but seven seeds. *S. oblata* and *azurea plena* were the varieties used. Other efforts were somewhat more successful. He has raised forty plants, of which number but three have bloomed, one of which is the above. The flowers resemble those of very small *Hyacinths*, hence the name.

A WRITER in the "Jahrbuch des Bremen'schen Gartenbau-Verin," on the change in the colours of flowers, says that the changes in the colours of the flowers of *GLADIOLUS VERSICOLOR* are among the most remarkable and wonderful of this class of phenomena. Indeed this plant may be dubbed a vegetable chameleon, so varied are the changes the colours of its flowers undergo. In the morning they are brown, and during the day they assume various hues, until in the evening they become blue, and remain so during the night. The following morning they are again brown, and during the day they pass through the same changes as on the preceding day.

*MR. PRINCE*, late gardener at Ringwood Hall, has succeeded to the management of the gardens at Bladon House, the seat of Fred. Gretton, Esq., Burton-on-Trent.

THE vegetable supply at COVENT GARDEN shows no signs of scarcity as the result of the hot and dry summer, but many vegetables do afford unmistakable evidence of rapid—in some instances too rapid—autumn growth. Cabbages are of immense size, and many of them are split. Cauliflowers are coarse and "blown." The majority of the Turnips are cracked, and Potatoes are the reverse of smooth and tempting in appearance; with but few exceptions the tubers are unshapely, and most of them show signs of second growth, and in some samples the second-growth tubers are larger than those of the crop proper. Endive and Lettuces are plentiful

and good; Celery generally coarse; Leeks small; Kidney Beans, Tomatoes, and Mushrooms in fair supply, and ridge Cucumbers and Vegetable Marrows are offered in large numbers.

ALLUDING to the SHOW OF FRUIT at the CENTENNIAL EXHIBITION at Philadelphia, the *New York Tribune* states that space is provided for 14,000 dishes, and most of it is already occupied. The Fruit-Growers Association of Ontario send 1500 dishes, and Apples from Nebraska are numerous and good. But "the most remarkable display in the building is that of California fruit, brought east in refrigerator cars. It is in fine condition. In size the fruit is unequalled, and its quality is very good. The Peaches are very large and temptingly luscious. Clusters of Grapes are shown, which in this part of the country seem fairly enormous. The beauty of some of them is beyond praise. The Apples, Pears, and Plums are almost equally remarkable. Nectarines, Figs, and Almonds, both green and ripe, are also shown. This fruit was brought here by an agent acting for a large number of fruit-growers. Besides that exhibited, a stock is on hand for sale in the building."

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

THE Asparagus stalks had changed to the yellowish tint indicative of ripeness, and we have had them removed. We like to cut them off before the seeds drop, as they vegetate next season and become troublesome weeds. Signs of the coming winter are to be seen in the falling leaves, which litter about the garden walks and give the place an untidy appearance; we contrive to sweep and clean up at least once a-week. Weeds have grown a good deal on the walks, and there is nothing for it but to pick them out by the hand, and this must be done at once, as the weather will soon be too cold for this sort of work. When walks have been laid down a number of years, and the gravel is loose, weeds grow abundantly; and if it is difficult to keep them under, a good plan is to slightly turn over the surface to the depth of 2 or 3 inches and give the walk a fresh dressing of fine gravel. When finishing off the walk ought to be left highest in the centre, but not so much as to be felt by the feet; a very slight rise from the side to the centre is sufficient to drain-off the water.

If Box-edgings require altering or relaying, the work ought to be done at once, so that the edgings become established before the winter. The gravel must be cleared well away from the side that is to be relaid, and the ground be forked over and well broken up; it should then be trodden down firmly and made perfectly level. When the line is tightly stretched cut the soil from the side next the walk with a clean spade, and when the Box is laid in it must not be more than about 2 inches above the surface of the soil. Box is by far the neatest and best edging where it succeeds. We have tried ornamental tiles, and they also form a neat and durable edging; but where they are only bedded in the soft ground or gravel they drop out of their position and require to be put straight about once a-year, and this is the best time to see to that. There are different sorts of gravel adapted for different circumstances, and there are different opinions as to which is the best sort of gravel for kitchen-garden paths. Preference is usually given to that which binds well; but in every case the foundation of the walks should be laid with rough stones or broken bricks, and if the subsoil is such that water does not drain freely through it, it may be necessary to lay drain-pipes along the paths. If a loose surface is preferred, the gravel must first be sifted to separate the large stones, then it must be passed through a finer sieve—one that will retain the smaller stones, passing the sand through only. The large stones must be put in at the bottom and the smaller on the top. There must be 2 or 3 inches of small stones on the top, else the larger stones will work up and be in the way. After it has been levelled smoothly with a rake a heavy roller must be passed over the path about six times to make it firm and perfectly level.

Slugs have been very troublesome on newly-planted Lettuce. We have dusted the ground over with quicklime; but the most effectual way to eradicate them is by hand-picking with the aid of a lantern at night.

### VINERIES.

THE damp muggy weather has been very injurious to ripe Grapes, and every precaution is necessary to prevent decay spreading amongst the berries. Immediately a decaying berry comes into contact with a sound one, the mould causes the sound one to decay. In such weather it is necessary to look over the bunches at least twice a-week, and to cut those decaying out. The thick-skinned variety, *Lady Downe's*, does not show any signs of decay, while many decaying berries have been cut out of the more delicate and thin-skinned *Muscat of Alexandria*. As a rule the white Grapes require the most attention,

but when it is intended that the fruit is to hang late in the season the berries must be well thinned-out. This is one reason why Lady Downe's keeps well, the bunches are usually small and never heavily shouldered. Gros Guillaume keeps well until after Christmas, but the bunches are usually large, heavily shouldered, and the berries are thinner-skinned than Lady Downe's. The larger bunches require to be examined to detect decaying berries in the centre. Mrs. Pince's Black Muscat does not keep nearly so well as Lady Downe's, but we have had the former in good condition until the end of February. It is needless to say much in praise of the well-known Black Alicante; it is next to Lady Downe's as regards keeping qualities, and superior to that variety in many important respects. One thing ought not to be lost sight of, and that is the importance of having the Grapes well ripened. The greatest care as regards ventilation and dryness of the atmosphere will not prevent badly ripened fruit from spoiling. The two essentials, independent of atmospheric influences and cleanliness, are well-thinned bunches and thoroughly ripened fruit.

Vines in pots now about to be started should be placed in a house without any artificial heat, as the weather is so mild. On six nights during the last week our minimum thermometer registered over 50°. Last Friday it did not fall below 58°. While this continues the house should be closed early in the afternoon, and a bottom heat of 80° will cause the buds to start strongly and regularly all over the canes. It is also necessary to syringe the canes with tepid water until the buds have started, when syringing may be discontinued. See that the roots do not want for water. A pot Vine that is in proper condition for forcing has the pot packed quite full of roots; and much of its food supply depends on the quantity of water the Vines receive. If any of the pots become overdry the result is most unfavourable to the Vines. For early forcing by far the best variety is the Black Hamburg. If a few white Grapes are required, Foster's White Seedling is good. Buckland Sweetwater is an excellent white sort and generally does well in pots, but early in the season the fruit is watery and deficient in flavour, unless the Vines can be placed in a position where they receive both the noonday and afternoon sun, in which case it is preferable to Foster's Seedling.

Fig trees intended for early forcing should not be left out of doors after this. Some persons recommend top-dressing them, but this is a plan I do not approve of for Figs; in fact, it is not a safe one for any tree or plant, except it is in full growth and the roots are ready to run into the surface soil at once. When the roots of plants are not very active the plant does not require much water, and if a rich dressing is put over the roots in winter it becomes sour before they penetrate into it; and further, the plant or tree requires no stimulant when it is leafless. Our own plan with Fig trees, and it is most successful, is this:—As soon as the leaves become yellow, or have fallen off, the trees are turned out of the pots and their roots examined. When these are in a healthy condition and well matted round the sides and under the ball of earth they are disentangled, and some of the soil is removed, repotting in a size or two larger pot. The Fig will stand a large shift, as it is a vigorous-growing tree and rapidly fills the pots with roots. We have put in eyes in February, and by shifting the young trees on as they required it, and growing them in a high temperature, we have had good-sized fruiting trees established in 11-inch pots by the end of the season. The trees should be potted in the same way and with similar compost as recommended a few weeks ago for Peach trees. When forcing is commenced the same system of management as that for pot Vines is the most suitable for Figs, and the trees luxuriate when in full leaf in a high moist atmosphere. If necessary, surface dressings may then be applied, and the healthy white roots will be through and through it in a few days.

#### PLANT STOVE AND ORCHID HOUSES.

Now is the time to have a thorough cleansing in these structures; the glass and woodwork we are having washed outside and inside. In the neighbourhood of large towns, especially where there is much smoke from factories, the glass becomes obscured from sooty particles in the atmosphere, and in winter the plants require all the light it is possible to obtain for them. Plants intended to produce flowers during winter should be placed in a light airy position. Winter-flowering plants are not numerous, and the most that is possible ought to be made of them. Some of the gayer-coloured handsome-foliated plants work in well with Ferns. Small plants of such, as *Sonerila margaritacea*, *Pittonia argyroneura*, *Bertolonias*, &c., have a fine effect as a margin to the stages alternated with the finer species of *Adiantum*. Some of the above are not only of easy growth but are also of rapid increase.

Cuttings of hardwooded plants put-in in August have now formed roots and made a little growth. They have been potted singly in small pots. All such plants require to be potted as soon as they are rooted, and the operation must be carefully performed. The whole ball should be turned out of the pot and the plants be picked gently from amongst the soil, saving all the slender thread-like roots. The compost for these small

plants ought to be much finer than that for specimens, and the pots must also be well drained.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

Thomas Rivers, Sawbridgeworth, Herts.—*Descriptive Catalogues of Fruit Trees and Roses.*

Jonathan Booth, Pole Lane, Failsforth, Manchester.—*List of Carnations, Picotees, Pansies, and Auriculas.*

Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Catalogue of Roses, Florists' Flowers, and Border Plants.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LIVERPOOL (Chrysanthemums). November 2nd. Mr. R. Wilson Ker, 6, Basnet Street, Church Street, Hon. Sec.

JERSEY (St. Helier's) (Chrysanthemums). November 8th. Col. H. Howell, Hon. Sec.

SOUTH BERMONDSEY (Chrysanthemums). November 13th and 14th. Mr. D. Jewiss, Rosedale Arms, Rosebury Street, Bermondsey, Sec.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Deunark Road, Northampton, Sec.

BRISTON HILL (Chrysanthemums). November 17th and 18th. Mr. G. Goldfinch, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

ISLE OF THANET. August 30th, 1877. Mr. C. D. Smith, Hon. Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

HORTICULTURAL DIRECTORY (*A Reader*).—It will be published early in January, price 2s. 3d., post free from this office. It is not too late to send corrections.

ROYAL HORTICULTURAL SOCIETY'S FRUIT COMMITTEE (*D. P. B.*).—It will meet in December.

ROOTS DESCENDING INTO GRAVEL (*J. P. J.*).—Cut off the tap roots at planting time, and place some slates or tiles at the bottom of the hole. Manure the surface and keep it well mulched to attract the roots towards the surface.

FUCHSIAS (*Mrs. Holmes*).—They are garden varieties which we cannot name.

TOUGHENED GLASS.—"*A Practical*" asks if anyone has tried Messrs. Dick Radcliffe & Co.'s toughened glass and found that it is equal to the praise bestowed upon it? He justly says it is valuable if it is tough.

GRAPES NOT SETTING (*J. B., Whitehaven*).—The Grape sent is the Royal Vineyard, which seldom sets its berries well, and is unsuited to your cool Black Hamburg house. You have adopted the best plan you could to improve the Vines, and if your inside border is rightly made the alteration will be effectual. The Vines were not likely to flourish in a border "only 3 feet wide, cold and wet."

FORCING SEAKALE (*H. W. S. C.*).—The seedling plants we presume are strong, having good crowns. If grown from seed this year the strongest only are available; the weakest plants if planted out will make good crowns for another year. The plants may be taken up as soon as the leaves have fallen or they part readily from the crowns, and the roots should be planted in rich soil up to the base of the crowns, making the soil firm about the rows. We put-in ours in rows about 8 or 9 inches apart, and 6 inches between the plants in the rows. The soil being moist at planting no watering is given until growth commences, and then we water between the rows twice a-week. All that is needed to ensure blanching is darkness. The heads will be fit to cut in fifteen or twenty-one days, and to keep-up a succession you will need to put in fresh roots at fortnightly intervals.

MARÉCHAL NIEL ROSE VIGOROUS (*Idem*).—Encourage the suckers from the root, in fact all the growth you have space for, awaiting with confidence the blooms that will astonish those who say you will not have any.

CUTTING CONIFERS (*A. F.*).—Beyond regulating irregular growths, cutting-back and trimming evergreens is not advisable. It is best performed in spring when fresh growth is being made. *Pinus excelsa* will bear cutting-back, and will probably give a shoot advantageously placed for replacing the lost leader, keeping any disposed to dispute its claims from asserting their right by timely removal. The pruning should be done a little before growth takes place.

REMEDY FOR AMERICAN BLIGHT (*Idem*).—There is no more safe and efficacious remedy than applications with a brush to the parts affected of paraffin oil, not allowing it to run down the stems or come into contact with the foliage. This and similar pests can only be overcome by frequent applications of the insecticide whenever the insect is present.

OLD AND YOUNG PLANTS OF VARIEGATED GERANIUMS (*F. J.*).—The old plants taken up from the beds and potted, having the irregular growths cut away and all but the very young leaves removed, will make larger plants than those from cuttings, but the latter give finer foliage; and as foliage is the

object in variegated plants, we consider young plants preferable to old plants, though we find the latter very useful for filling the centres of the beds with the young plants on the margin. The old plants do not require to be started in heat, but should be kept rather dry until they start into growth. Plants in frames will keep safer from frost at a distance from the glass of 12 inches rather than 6 inches, but if frost be excluded the nearer they are to the glass without touching the better.

**POTATOES (Tubers).**—You may justly expect a good crop next year on old grass land broken up, although you have had a crop of Potatoes this year. Have the dead seeds well divided, and plant Ash-leaved Kidneys next April.

**MULBERRY GERANIUM (W. W.).**—You may have a rooted cutting in the spring.

**CEDRUS DEODARA CONES.**—The Rev. H. Bullock says that they are on a tree in his vicarage garden at Ewyas Harold, Hereford.

**HIPPEASTER (Miss Smith).**—The bulbs you have received with this name belong to the genus *Hippeastrum* and the natural order, *Amariyllidaceae*.

**SELECT GLADIOLI (C. Thomas).**—*Twelve extra-fine Gladioluses*—French varieties are: Genevra, Leda, Pactole, Marillo, Ondine, Psyche, Le Vesvre, Jupiter, Meyerbeer, De Mirbel, Horace Vernet, and Christophe Colomb. *Twelve second best:* Adolphe Brongniart, Ariadne, Delicatissima, Eugène Scribe, Le Phare, Legouvé, Madame Desportes, Madame Furtado, Marie Stuart, Michael Ange, Orphée, and Shakespeare.

**RHOIODENDRONS FOR FORCING (Ireland).**—The varieties you name may be plunged—just covering their pots—in a sheltered position in your garden until you require to place them under glass.

**SCALE ON CAMELLIAS (W. E.).**—Deficient moisture in the air of the house promotes the production of the scale insect. The following mixture is a remedy:—Soft soap, 2 lbs.; flowers of sulphur, 2 lbs.; tobacco, 1 lb.; and a wine-glass of spirits of turpentine. Mix the sulphur, turpentine, and soap into a paste with warm water; boil the tobacco for an hour in a covered saucepan in some more water, strain it, mix it with the soapy mixture, and then add enough water to make five gallons. More tender plants can only have their stems and leaves sponged with water at a temperature of 115° frequently, and so long as a single insect can be detected.

**HOLLYHOCK LEAVES DISEASED (J. P. A.).**—They are infested with the Hollyhock parasitical fungus, *Puccinia malvacearum*. Cut off all the leaves immediately and burn them, and dust over the stumps of the plants with flowers of sulphur.

**SOIL OF FLOWER BORDERS (P. McL.).**—Apply well-decomposed stable manure early in the spring, and point it in with a garden fork.

**MANURE FOR STRAWBERRIES (E. Gabray).**—If the soil is poor, stable manure may be dug into it previously to planting. Burying it 2 feet is bad practice. It should be mixed with the upper foot of soil. Bone manure between the rows should be also dug-in with a fork.

**WIRE FOR FRUIT TREE TRAINING (Careful).**—Galvanised iron wire three-sixteenths of an inch in diameter is the most generally serviceable.

**MEDLARS (An Amateur).**—Keep them in a cool place until they are decayed, or bletted, which is the technical name of the decayed state. They are then an excellent dessert fruit. The plant enclosed is Sweet-scented Verbena, *Aloysia citriodora*.

**BLACK CHERRY FOR WALL (H. F. C.).**—Against your south-west wall plant the Black Tartarian. It is quite hardy, large, and most excellent.

**DISTANCES FOR PLANTING FRUIT TREES (J. E.).**—Apples and Pears as espaliers should be 18 feet apart, and Pears on the Quince as standards should be 16 feet apart; but we would plant them 8 feet at first, and thin them out to 16 feet when the trees become crowded.

**FRUIT TREES FOR MARKET PURPOSES (J. B.).**—We advise you to grow those varieties that succeed well in the neighbourhood in which you live. The Prune and Damascene are the same. You should try the Cluster Damsen or Crittenden's Prolific. It is a good bearer, and the fruit large. You could not have seen the true sort. Your selection of Plums is a good one. Have you tried Early Prolific for the earliest variety? It is the earliest one. Have you seen what has been said about Domino Apple in our pages. Balossa, Croft Castle, and Heesle are Pears that bear enormously. You omit Williams' Bon Chretien, Suffolk Thorn, Jargonelle, Windsor, and Beurre d'Amanlis from your list. They are all free-bearing sorts in the open ground. Some late varieties of Pears bear as freely as early sorts.

**GRAPES DECAYING (A. B.).**—The immediate cause of the decay of your Grapes is the heavy rains succeeding a long period of drought, the rains falling just at the time the Grapes commenced ripening. The border, by the long term of sunny weather, had become unusually warm, and the moisture it has since received has caused the roots of the Vines to be exceedingly active, furnishing more sap to the Vines than the foliage could appropriate and exhale—hence the bursting of the berries. That is the immediate cause of the decay. We further consider that your Vine border is deficient in phosphates, which accounts for the extreme thinness of the skins of the berries. As you have surface-manured your border for some years we advise you to carefully remove a few inches of the surface soil—just boring but not injuring the roots, and replace with fresh loam and crushed bones—3 cwt. of bones to a good cartload of loam. This would give stamina to the Vines. You can afterwards surface-dress the border with manure as usual. If you give this change of food and do not overcrop the Vines, the Grapes will acquire more substance of cuticle, and will be less liable to decay than in their present state. Had you covered the border and prevented the rain entering it at a critical time, your Grapes would have kept better. Your real remedy, however, is to reduce the humus and increase the phosphates in the border by the means suggested. If you can add charcoal and wood ashes to the loam and bones we advise you to do so. By adopting the mode now recommended we have greatly improved Vines which were in a similar condition to yours. We suspect also that you have been overcropping.

**NAMES OF FRUITS (Connaught Subscriber).**—The single Pear is Gansel's Bergamot. No. 1, Winter Nalis; 2, Comte de Lamy. (John A. Huggan).—Bonset de Rheims. (H. F.).—It is a Physalis, or Cape Gooseberry, and not admissible in a collection of fruits for exhibition. (R. Cordell).—Golden Pippin is the Apple. The Ferns had no spores. (Scybor).—174, Nectarine Pear; 102, Beurre d'Amanlis; 205, Beurre Hardy; 123, Bellissime d'Hiver. The rest were decayed. (D., Guernsey).—A, Ord's Apple; B, Blenheim Pippin; C, Formosa; D, Dumelow's Seedling; E, Blenheim Pippin; F, Formosa. (Devon).—2, Baxter's Pearmain; 4, Ribston Pippin; 5, Morning Pippin. (L. R. Lucas, jun.).—Apples: 2, King of the Pippins; 8, Scarlet Nonpareil; 17, Warner's King; 20, Adams' Pearmain. Pears: 1, Botten; 3, Fondante

d'Antonne; B, Bellissime d'Hiver. We cannot name more than six specimens. (Connaught Subscriber).—Apple: Pearson's Plate. Pear: No. 1 cannot be identified; No. 2, Leopold I. (Knutsford).—1 is a fine Apple, and is new to us; 2, Osterley Pippin; 3, not known.

**NAMES OF PLANTS (Mrs. L. Fox).**—*Eucynymus europæus*, Spindle Tree. (A Constant Reader).—We cannot name from leaves without flowers or fronds without spores.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LES BASSES-COURS D'ANGLETERRE.

#### CHAPTER IX.—CREETING, NEEDHAM MARKET.

OUR first view of Mr. Horace Lingwood's Brahmas was across the river. We had walked from Needham station by the side of the water, and when we came to the mill we came to the Brahmas. We cannot easily forget that first peep. It had been a showery morning, but at that moment the sun was shining brightly, and the leaves just tinged with the autumnal shades shone with the drops upon them; while underneath, quite down among the rushes and sedges at the water's edge, were the world-renowned Brahmas. Instantly it flashed across our minds what Mr. Lingwood had so often written to us: "Mine is a beautiful summer place for poultry, but in winter it is terribly bad." We can only say, after anyone has seen the place for the first time, they must wonder as much as we did at the marvellous career Mr. Lingwood has enjoyed. The yards are all on the side of a little hill, and slope down to the edge of the river; they are thickly planted with large trees, and divided by wire netting. The houses are quite plain, and made of wood. There is no pretence at decoration or ornamental work which some might expect in so great an establishment, but everything seems to have been done to economise space and to make the most of everything. When we thought how for year after year the enormous winning cockerels at all the great exhibitions have come from this yard, we at once realised what skill and judicious mating and personal management can do.

This year, so far, Mr. Lingwood has certainly been behind, but it will not be for long, for we venture to think that we saw some cockerels coming on which will perfectly keep up the world-wide reputation of the Creeping Dark Brahmas. Of one thing, however, there is no doubt; an immense number of birds have been reared year after year on a very small space, and this cannot go on for ever, so it is possible that the land has become tainted, and consequently it is more difficult to keep the birds in health. Mr. Lingwood believes this himself, and this is why he is so anxious to find a fresh home with better poultry accommodation. We could only think what a pity it is that he cannot possess a few of the rich broad acres of grass that surround him closely on every side, which would then make the place a Brahma manufactory second to none, for as it is the wetness of the ground must be a very serious drawback and loss. But we will pass on to the birds.

In front of the house is a good-sized lawn surrounded with shrubs. Here the chicks are brought as soon as hatched, and when the chickens are able to pass from this run it is used again no more, but is reserved for the broods of another year. Going from this lawn we pass to the back of the house, where we find on a little run by the back door what is to our mind the hero of the yards. It is the grandest old Dark Brahma cock we ever saw; he was just getting over his moult, and with hackles the colour of a new shilling. He seemed to walk about as if "Crystal Palace first-and-cup" was written on his back. Next to him, in a run only divided by some wooden palings, were the Dark hens. We were told that they had died by half-dozens this year from some complaint which Mr. Lingwood puts down as arising from the tainted ground, but we have heard right and left this season of deaths among Asiatic hens. Some of these were still in deep moult, some just getting over it, but through old and new feathers we saw good pencilling and good shape. Then we saw old cocks (Lights and Darks) in small grass runs with tents over them. This was to keep off the sun, and we can well believe they prove very useful. Among the imates we noticed one or two splendid fellows nearly over their moult; and among all the others, who were still in "rags," we observed those neat combs and those broad backs which so mark Mr. Lingwood's strain.

The next yard was the pullet run, and this we liked the best of all. It was a triangular piece of ground, and quite on the slope. Here and there peeped out large pieces of red rock, among which the pullets had apparently made a miniature mountain pass; and as we looked at them the whole lot, quite thirty we are sure, went out for a walk, and passed one by one in single file, like so many Ducks, up the steepest part. As they passed we had a good view of every one of them, and a splendid lot they were, one or two being, perhaps, much more remarkable for pencilling than the others, and these were mostly quite young and undeveloped as yet; but we noticed here, we thought, as we have done in so many places and at so many shows, that as a rule the best pencilled birds are not the best

in shape, size, or feathering. Charming as this run looked when we saw it, we can imagine the lower part of it being a "Slough of Despond" in the winter, for when the river rises all the bottom portion is under water. Next we visited the cockerels, and a good many there were more backward than usual of course, or we should have seen them out before now, but still of great promise; one especially, still quite raw and undeveloped, caught our eye whenever we looked at them. There were about twenty in the run, and we drove them this way and that way, but on every occasion this one bird caught our eye. "That cockerel if he lives is destined for great things," we said to Mr. Lingwood; still the others were all good, and one or two not much behind the one which we spotted as "the coming B." There were some more good Light and Dark hens in the next run, and then we too climbed up the bank and found the single cocks' pens on the top. They were under the trees, and gave us the idea of being rather "drippy" in winter. Someone said to us the other day, "Chickens will should be shaded in just such a way that ferns would do well in them, for ferns like shade without drip, and so do chickens." Well, we do not think ferns would grow in Mr. Lingwood's single cocks' pens. The birds themselves looked healthy, and appeared to be moulting out well. Lights and Darks there were, all birds which have made names for themselves as chickens, and will in days to come make names for themselves as adults. We had now seen all the birds, and when we had had one more look at the pullets, who were still busy walking up and down among the rocks, we went away, and left with the certain impression that Brahma fanciers will in the shows to come have as much to fear from the Creeting monopoliser, especially in adult cocks, as ever they have had to fear in past seasons.—W.

### POULTRY AND BIRD NEWS.

CIRENCESTER has issued its schedule. There are no Dorking or Spanish classes. The Judges are announced, and are amateurs of high standing—namely, the Rev. W. Serjeantson, Messrs. O. E. Cresswell, and Samuel Matthews. We congratulate the Society on their selection, and wish them much success.

We learn that the Judges at the coming Dairy Show are—for poultry, the Rev. T. Fellows and Messrs. Lowe and Leno and Capt. Heaton. We are sorry this Show was not better classified, and that it chose its dates for the same days as Oxford, especially as the latter had been advertised for those days fully twelve months ago. Such good prizes and low entry fees deserve support.

We have many schedules come to hand, among them those of the Crystal Palace and Bristol. The former is much the same as usual, only the entry fee is raised to 3s. the pen. We consider this very wrong; at Oxford for 63s. first prize the entrance fee is only 6s. We will review Bristol later on; it has many new classes, and deserves great support.

The entries at Oxford have closed with a very great advance in numbers over former years. This shows surely the great faith the public must have in the management of this Exhibition. We recommend all fanciers to attend if possible, for the quality of the entries promises to be very select, and in nearly every class to be very large.

All fanciers who are desirous of the judges' names being announced in the schedules of exhibitions should send in at once their names to Mr. Wallace Smith, Breeze Hill, Walton-on-the-Hill, Liverpool, as this gentleman is getting up a memorial to managers of shows to claim this convenience. We hope all will assist in this laudable undertaking for the good of the fancy.

All who are in the habit of attending poultry exhibitions will know Mr. Beldon's manager, Job, and they will probably be surprised to hear that he has left the Goitstock yards and has set up for himself. We understand his successor is Mr. Lowe, who had for some time been with Mr. James Long, and previously with Mr. O. E. Cresswell of Bagshot.

No more news has been heard of the Portsmouth Committee. We believe one or two are bringing them to book by law. We wish these every success, and hope those who took 10s. in the pound will live to repent having backed up such a miserable arrangement.

Capt. Noman Hill has presented a £15 15s. cup for the best standard Pied Pointer cock, to be competed for at the coming Palace, Belfast, and Edinburgh Shows.—W.

### NOTTINGHAM SHOW OF POULTRY, &c.

This was held on the 3rd, 4th, and 5th inst.; but we never heard of it until ten letters came to ask for the awards. If Committees will not advertise their forthcoming exhibitions they must be often overlooked.

POULTRY.—COCHINS.—1, Miss B. Borton. 2, R. P. Percival. 3, W. A. Bunnell. BRAHMAS.—1, R. P. Percival. 2, R. Garner. 3, A. S. Webb. GAME.—1, Earl London. 2, J. Nicoll. 3, H. E. Martin. SPANISH.—1, J. Aldridge. 2, H. Blower. 3, J. Thresh. HAMBURGERS.—1, J. Smith. 2, P. Hinds. 3, A. S. Webb.

GAME BANTAMS.—1, O. Cliff. 2, W. M. Griffin. 3, F. Steel. BANTAMS.—1, H. Dracott. 2, J. C. Fraser. 3, J. Calladine. ANY OTHER VARIETY.—1, Dr. Snell. 2, J. & J. Dennison. 3, B. Smith. SELLING CLASS.—1, W. A. Bunnell. 2, H. Yardley. 3, S. T. Vernon.

PIGEONS.—POUTERS.—Cock.—1, J. Baker. 2, J. Martin. 3, F. Gresham. Hen.—1, H. Simpson. 2 and 3, J. Baker. CARRIERS.—Cock.—1, J. Baker. 2, W. F. Footitt. 3, J. E. Palmer. Owl.—1, G. Kempton. 2, J. E. Palmer. 3, H. Parker. Young.—Cock or Hen.—1, T. H. & A. Stretch. 2, W. Cartwright. 3, A. Birkleald. BARBS.—Cock or Hen.—1, J. Baker. 2, T. Hives. 3, H. Yardley. TUMBLERS.—Almond.—Cock or Hen.—1 and 3, J. Baker. 2, H. Yardley. Short-faced Balbs or Beards.—Cock or Hen.—1 and Medal. H. Yardley. 2, J. W. Edge. 3, J. Baker. Any other variety, Short-faced.—Cock or Hen.—1 and 3, J. Baker. 2, M. Weston. Any variety, Long-faced.—Cock or Hen.—1, J. W. Edge. 2, W. Wood. 3, J. Spencer. English.—Cock or Hen.—1, R. Wood. 2, H. Parker. 3, J. Baker. Foreign.—Cock or Hen.—1, J. Hawkins. 2, T. Hives. 3, J. C. Taylor. DRAGONS.—Blue or Silver.—Cock or Hen.—1 and 3, R. Woods. 2, H. Yardley. Any other colour.—Cock or Hen.—1, 2, and 3, R. Woods. ANTWERPS.—Short-faced.—Cock or Hen.—1, H. Yardley. 2, H. W. Weaving. 3, J. Mantel. Long-faced.—Cock or Hen.—1, 2, and 3, G. F. Herrieff. FANTAILS.—Cock or Hen.—1, J. Walker. 2 and 3, S. Swift. JACOBS.—Cock or Hen.—1 and 2, J. Baker. 3, G. C. Taylor. ANY OTHER VARIETY.—Cock or Hen.—1, R. Woods. 2, J. Baker. 3, H. Yardley. SELLING CLASS.—Cock or Hen.—1, R. Woods. 2, W. Woodhouse. 3, J. Baker.

CATS.—SMOOTH-HAIRED ENGLISH.—Male or Female.—1, R. Kitching. 2, Mrs. R. Hill. 3, C. W. Saywell. FOREIGN OR LONG-HAIRED.—Male or Female.—1, Mrs. Cheshire. 2, Mrs. Briggs. 3, G. Osborne.

JUDGES.—Poultry: Mr. E. Hewitt. Pigeons: Mr. F. Esquilant. Cats: Mr. J. Forman.

### MIDDLETON SHOW OF POULTRY, &c.

THANKS to the energy of the Secretary (Mr. Mills) and a few of the old Committee, new vigour has been added to this Society, and may we have to refer again and again to similar successes. The pens for poultry were of the old-fashioned type, but answered the purpose well, although these must be difficult of storage from year to year.

Game headed the list, and the entries were good, the colour predominating being Brown Reds, of which there were some first-rate birds, especially in pullets. In the variety of Game cockerels first was a Duckwing grand in all respects but tail, which was rather heavy; and in pullets was one of the best Blacks we have seen of late. Spanish were good in both classes, but Dorkings were not at all up to them, some being rather rough if large; Brahmas were only a moderate lot. As may be expected, the Hamburgs were a grand lot, the Gold-pencils were particularly bright in colour, the Silver-pencils being quite equal to them. In Gold-spangled cocks first was a very cheap bird, and was speedily claimed at 30s., and was a capital bird as regards marking. In hens the awards were made to the light shade of ground colour; one of a particularly rich deep ground, we thought would win, being passed over. French pout, except the first in each class, which were Crèves. In the Variety class the winners were Polish in all cases, Mr. Boothby's grand Golden hen being speedily bought at £10. Game Bantams seemed to be a rather rough lot in cocks, though rightly placed; but the hens were better, Black Reds and Piles winning. In Aylesbury Ducks first were a grand young pair, the drake turning the scale at 10 lbs. Rouens were also very good. In the Variety class first were Malagas, and second Mandarins.

Pigeons a fair entry, but the pens too small for all but the smallest varieties. In Carriers Dun and Black won respectively in both classes, the first in both cases very good in wattle. Pouters only three. In Turbits Blues won; both fair birds. English Owls a large class, but the cards not being put up till late we had a difficulty in obtaining the awards. Nuns and Magpies were—first a Nun, and second a very good Yellow Magpie. Dragons a fair lot; first Silver and second Grizzle. Antwerps were good in every section, and the awards well made. In the Variety class first was a neat little White Owl, and second a Blondinette.

Of Rabbits there were fifty-eight entries, but some pens were empty. In Lop-ears first was a Fawn of good measurement, but the award was a decided mistake, the fore legs being very crooked, which doubtless escaped the eye of the Judge. Angoras and Himalayans were poor, except those noticed, the first in the latter class far ahead of the rest.

POULTRY.—GAME.—Black-breasted and other Reds.—Cock and Cockerels.—1, C. W. Brierley. 2, J. Cook. Hens and Pullets.—1, C. R. Kay. 2, R. L. Garnett. Any other variety.—Cocks and Cockerels.—1, H. E. Martin. 2, T. Hives. Hens and Pullets.—1 and 2, C. W. Brierley. Any other variety.—Cocks or Pullets.—1, T. P. Lyon. 2, T. Dyson. SPANISH.—Cocks and Cockerels.—1, R. Newbitt. 2, J. Thresh. Hens and Pullets.—1, J. Thresh. 2, R. Newbitt. DORKINGS.—Cocks and Cockerels.—1 and 2, J. Walker. Hens and Pullets.—1, J. Stott. 2, J. Walker. BRAHMAS.—Cocks and Cockerels.—1, T. F. Ansell. **JUDGES.**—*Poultry:* Mr. R. Teebay and Mr. S. Fielding. *Pigeons and Rabbits:* Mr. J. Hawley.

### MONMOUTH POULTRY SHOW.

THIS capital Exhibition was held in the market, and the quality of the birds exhibited was very good. The poultry were judged by Mr. John Martin, and his awards were very well received, in fact we seldom heard so little complaining. The Secretary did his best, and was very courteous to all. We could not find the address of exhibitors in the catalogue, an omission which we consider a mistake. The quality was on the whole good, and we think the Show annually improves under the same management and under the same Judge.

Dark *Brahmas* opened the list, but they were a poor lot, and we saw neither size nor shape among the cocks, or pencilling in the hens and pullets. The first and second Light *Brahmas* were very good, but the third was not awarded, and here, as in the Darks, we saw no great advance. Coloured *Dorkings* made a neat class of half a dozen pens; a very fair pen of old birds won first, while chickens won second and third prizes. *Cochins* made a very good class; a capital pen of White chickens won first, while second and third went to good Buffs, as all colours competed together. *French* fowls call for no comment; a good pen of *Crêves* won first, and *Houdans* second. In *Polands* a very smart pen of White-crested Blacks were first. We are indeed pleased to see how this variety is daily, so to speak, gaining popularity. Very fair *Silvers* won second and third prizes. *Hamburghs* had a good many classes, and did not respond very satisfactorily. The Golden-spangles were the best in quality, the winning pen being extremely neat and good in colour. We much admired the markings of the first Golden-pullet (pencilled). There were only two pens of Silver-pencils, and they were only moderate. *Spanish* made a very poor display, and Mr. Dean, who seems to turn his hand to every breed, won first. In the *Game*, which were all classified together, Black Reds of good quality won first. *Game Bantams* followed their larger relations; a splendid pen of Black Reds were well in first, being smart in carriage and good in colour. The variety *Bantam* class was a capital one; a beautiful pen of Whites won first, good Silver-laced second, and neat Blacks third. In the *Any other variety* class a very good pen of *Silbies* won first, while second went to fair White *Dorkings*, and third to moderate Black *Hamburghs*. *Waterfowl* were capital, *Aylesburys* and *Rouens* being both very good. In the fancy Duck class were some neat White Calls, which we hope are entered for Oxford. The table fowl classes were failures, and such classes are not needed at prize-stock exhibitions. The Selling class was for a cock and two hens, price not to exceed £2. Now, who can expect to get three good birds for 40s.? and no one wants bad or moderate birds. We doubt very much the benefits that these sale classes are supposed to effect. *Geese* and *Turkeys* were good, and the quality up to a high standard, though the number of entries was not large. We give the prize list below:—

**POULTRY.**—**BRAHMAS.**—Dark.—1, E. C. Penke. 2, E. Pritchard. 3, T. A. Dean. **Light.**—1 and 2, T. A. Dean. **DORKINGS.**—Grey or Coloured.—1, A. Darby. 2, H. Wynne. 3, J. Ashworth. **COCHINS.**—1, Rev. R. S. Woodgate. 2, J. Ashworth. 3, A. Darby. **FRENCH.**—1, E. Williams. 2, S. W. Thomas. 3, E. Barnett. **POLANDS.**—1, A. Darby. 2, C. Bloodworth. 3, J. Ashworth. **HAMBURGHS.**—Golden-spangled.—1, J. Ashworth. 2, C. May. 3, J. Ward. **Golden-pencilled.**—1 and 2, J. Ashworth. 3, E. Ashpole. **SILVER-SPANGLED.**—1 and 2, J. Ashworth. **SILVER-PENCILLED.**—1 and 2, J. Ashworth. **SPANISH.**—1, T. A. Dean. 2, J. Manns. 3, R. Godsell. **GAME.**—1, J. P. James. 2, J. Ashworth. 3, T. Henry. **BANTAMS.**—Game.—1, R. Y. Ardagh. 2, J. C. Fraser. 3, J. Andrews. **Any other variety.**—1, J. Ashworth. 2, J. W. Lloyd. 3, T. F. Phelps. **ANY OTHER VARIETY.**—1, Rev. R. S. Woodgate. 2, A. Darby. 3, A. Trickett. **DUCKS.**—Aylesbury.—1 and 2, E. A. Bailey. 3, J. Ashworth. **Rouen.**—1, E. Lawrence. 2, J. S. Maggs. 3, J. Ashworth. **Any other variety.**—1, J. Trickett. 2, E. A. Bailey. 3, Mrs. Rolis. **SELLING CLASS.**—1, T. A. Dean. 2, D. Lewis. 3, H. Haddrell. **TURKEYS.**—1, E. A. Bailey. 2, Mrs. Rolis. **GEES.**—1, E. Shaw. 2 and 3, E. A. Bailey.

### HULL BIRD SHOW.

THE first Show of fruit and cage birds was held in the Rifle Barracks, Hull, on the 10th inst., the entries in the latter section being close upon two hundred. The arrangements were very good, all being well placed for inspection, and the light even and good. First on the list were Belgians, but only the winners in

these were of any note, the first a bird that had evidently been touched-up before, and knew his work; second also a superior bird, but not in good feather. First Yellow, and second and third Buff. In the half-breeds were some choice specimens, very light and clear in feather, but many showed too near relationship to the foreign type. Norwich (Yellow) were all clear and capital in colour, as also the Buffs, and there were some capital birds among those noticed. In the Marked of Any breed first was a four-pointed Jonque Norwich, second a Variegated Jonque Norwich, and third a Yorkshire four-pointed, but one tail feather being out, placed it lower than it otherwise would have been. Goldfinches poor, except the first, this being a bad time for these; none of the Linnets were in full bloom, although for the most part they were neatly moulted. Blackbirds and Thrushes were superior, especially some birds of the latter variety, but some were on the highway to ruin by the almost entire feeding upon hempseed. Larks a bad lot. Cage of six Canaries were—first Belgians, second Yorkshire, third Norwich, and fourth Lizards; the first a very good lot. In British birds the winners were Starlings. Grey Parrots a fair lot, the gem of this section being a splendid King Parrot in grand order. Under the head of Love Birds were included Budgerigars, a mistake in our opinion, and consequently the latter were excluded from the next class, which was really their proper place. In this class a pair of White Java Sparrows were awarded first, second Mannikins, and third Whydahs. Lizards were a very attractive class, the spangling of some of the specimens being really perfect; but only the first was perfect in cap, the third being out a little too low on one side, the second being close on the heels of the first. Points prizes were won as follows:—Canaries—Mr. Grantham, Hull; Foreign birds—J. Coker, Hull; British birds—Solomon Alcock, Hull.

**CAGE BIRDS.**—BELGIAN CANARIES.—Clear or Ticked Yellow or Buff.—1, J. N. Harrison. 2, L. Menechie. 3, J. Swain. **Half-bred Yellow or Buff.**—1 and 2, J. Swain. 3, J. Hogarth. **vhc.** J. Baines. **NORWICH CANARIES.**—Clear or Ticked Yellow.—1 and 2, W. Grantham. **vhc.** J. N. Harrison. **Clear or Ticked Buff.**—1 and 2, W. Smith. 3, R. Pearson. **MARKEED CANARIES.**—Any Breed.—1, J. Young. 2, W. Smith. 3, J. Thackley. **vhc.** R. C. Jobling. **W. Smith.** **GOLDEN and CANARY MILK.**—1, R. C. Jobling. 2 and 3, Strouds and Goode. **vhc.** W. Grantham. **GOLDEN or BUTTERFLY.**—1, G. Coker. 2, T. Green. 3, L. Menechie. **LINNETS.**—1, R. Pearson. 2, W. H. Batchelor. 3, L. Dickenson. **vhc.** J. Hogarth. **BLACKBIRD or THRUSH.**—1, —Watling. 2, —Coultas. 3, L. Menechie. **vhc.** Mrs. Alcock. **J. Hall.** **LARKS.**—1 and 2, J. Barnes. 3, G. Coker. 4, H. T. Holdenby. **CAGE OF SIX CANARIES.**—1, W. Grantham. 2, J. Thackley. 3, J. Young. 4, G. Ostler. **ANY OTHER VARIETY OF BRITISH BIRDS.**—1 and 2, Mrs. Alcock. **vhc.** R. Baxter. **PARROTS.**—Grey.—1, T. Talnes. 2, Mrs. Jackson. 3, J. Scott. **Any other variety.**—1 and 2, J. Coker. 3, H. Talnes. **PARROQUET or LORRY.**—1, J. Whittaker. 2, Sir T. A. Constable. **Bart.** 3, J. Coker. **COCKATOO.**—1, J. Coker. 2, M. Jackman. 3, Mrs. J. Chappell. **LOVE BIRD.**—1, J. Coker. 2, 3, and **vhc.** J. Coker. **Extra.** Mrs. J. Chappell. **ANY OTHER VARIETY OF FOREIGN BIRDS.**—1, J. Coker. 2, R. Baxter, jun. 3, J. C. Griffin. **LIZARD.**—Gold or Silver-spangled.—1, J. N. Harrison. 2, J. Thackley. 3, Cleminson & Elerton. **vhc.** G. Ostler. **ANY VARIETY.**—1, —Gowen. 2, J. Coker. 3, J. Baines.

**JUDGE.**—Mr. E. Hutton, Pudsey.

### PRESTON PIGEON SHOW.

THE first Show, which is intended to become annual, was held in the Bull Assembly Rooms on the 11th and 12th inst. The entries were very good, being about 450 in all, but nearly three hundred had to be refused on account of the incapacity of the room to accommodate them.

Carriers headed the list, and in cocks were some good birds, the first going to a Black in good order; the second, a Dun, was young, very promising, but not quite up in feather. In hens the first and cup for the best bird in the Show was awarded to a capital Dun a little short of beak wattle, but in splendid form; second a Black, good in beak, but not so good in eye wattle. Pouters were—first a White in capital blow; second Black, a little dull in colour; and third Blue. All cocks. In Almonds a hen was put first and a cock second, both good and well broken. Jacobins a very good class. The first a snug-looking Red, and second of that colour, the third Yellow, good in points, but a little coarse. Turbits, first and third Silvers, and second Blue, all good and clean-thighed; and in the next class first was a Yellow, as also second, the third Black. The first was the better class. Fantails a fair lot, but some not quite out of moult; second was a Blue. English Owls were both large classes, and in cocks were some very perfect-headed birds. First and second Blue, and third Silver, nearly every bird being noticed. Hens were not as good as a whole, but a grand Silver headed the list, the others being Blue. Dragons, Blue or Silver, produced some perfect-headed birds, Blues winning in two cases and Silvers third. Red and Silver were not superior as a class, but the winners were good; the Red placed first was a slashing fellow, second a Yellow. Any other colour were—first and second White, and third Grizzle. The Young class was very large and uncommonly good. The first a Yellow, second Silver, and third a Blue. Antwerps in all classes were very good, and even these seem to be improving in style, which is very desirable. Trumpeters were a better class than is usually seen, and the prizes were won by the same exhibitor. In Tumblers, Long-faces, first was a neat sound-coloured Yellow Mottle, second a Bald, and third a Beard. In the Variety class first was a White Owl, second a

Blondinette, and third a Fairy Swallow. The Selling classes were large, and contained some cheap birds, some of which changed owners.

**PIGEONS.—CARRIERS.**—*Cock*.—1, E. Beekwith. 2 and 3, J. Kendall. *who*. H. Yardley, J. Kendall, E. Beekwith. *Hen*.—1, J. Kendall. 2, E. Beekwith. 3, H. Parker. *who*. H. Parker, T. H. & A. Stretch, E. Beekwith. **POULTERS.**—*Cock* or *Hen*.—1, E. Beekwith. 2, E. A. Thornton. 3, J. Royle. *who*. A. P. Byford, H. Crosby. **TUMBLERS.**—*Short-faced.*—*Cock* or *Hen*.—1 and 2, H. **JUDGES.**—Messrs. E. Hutton and W. Sefton.

## DO BEES GATHER HONEY OR MAKE IT?

My simple answer to this question, which has been again brought to the front in this Journal, is that the latter is an impossibility. Unless bees bring sugar into their hives apart from the substance which Mr. Pettigrew calls crude honey, or excrete it from their own bodies, they gather it abroad from fruit or flowers, or in rare instances in the form of honeydew. Mr. Pettigrew's notion is that bees excrete it from their own bodies, and in support of his opinion he quotes the statement of a certain Professor Riley, an American, by whom the truth is so well told that Mr. Pettigrew ventures to repeat it in two successive issues of this Journal. "Honey," he says, "is a secretion of bees to some extent as well as wax." But presently he says that the "crude honey found in flowers and gathered by the bees is afterwards changed and converted into honey proper. After having been gathered and disgorged it is reswallowed, and then passes through a process of preservation, in which it is thickened and sweetened, resulting in honey, as the Professor puts it." With all respect to Mr. Pettigrew I must say, as I have said before, that these random and curious assertions are not proven, and therefore the truth of this presumed fact is still lying in dreamland.

It is singular to observe how ready Mr. Pettigrew is to endorse the notions and statements of this American gentleman, happening as they do to coincide with his own opinions, whereas a while ago, in respect to the value of Italian bees, the testimony of a number of Americans was ridiculed and condemned by him, in common with everything from America, in the most unmeasured terms. I repeat, with all respect both for Mr. Pettigrew and his American friend Professor Riley, that we have as yet nothing but bare assertion for all these curious statements. True, there is an allusion to a certain other American, a "chemist and botanist of Louisiana, who described the changes undergone by nectar in the elaboration into honey in the bee's stomach." Now this is just what we want to know. Will Mr. Pettigrew favour us with the data upon which this chemist founded his argument? Doubtless the same authority which notified the fact to the "Housekeepers' Convention in St. Louis," also contains the details of this remarkable discovery, which certainly was new to the *Journal of Horticulture* till it was mooted by Mr. Pettigrew. I can imagine no more interesting subject to bee-keepers, on which the patient and exhaustive mind of the scientific President of the British Bee-keepers' Association, Sir John Lubbock, might be brought to bear, than this question of the presumed manufacture of honey in the stomach of the bee, if indeed he should think it worth a second thought. At present I say we have nothing but statements and assertions in support of the theory, which without the most satisfactory proofs will remain assertions and nothing more, however frequently and persistently reiterated.

The secretion of wax from honey is an entirely different thing, for honey is known to be little more than the quintessence of sugar, which contains the fatty elements which are the ingredients of wax. But where does the sugar come from? Mr. Pettigrew says it is not found in the crude honey gathered in the flowers, it is elaborated in the stomach of the bee. Is it so? Prove it, I say. It must, however, be elaborated out of something in the stomach of the bee. For "out of nothing

comes nothing." Now, Mr. Pettigrew, please to tell us what is that something out of which bees make honey; but in the name of everything that is scientific, do not repeat the same tale in the same form. Till the proof positive is furnished, or at least till reasonable grounds for believing such a very extraordinary thing are supplied us, nobody will be convinced whose opinion is worth a groat.

Of course, we all know very well from our first practical experience of honey, that at first, especially at certain seasons, particularly towards the close of the honey season, it is thin and watery. You may call this crude honey if you like. I do not object to the term. Also, of course, we all know that bees transport the honey from cell to cell. At first they put it into any vacant cell which happens to be ready for it. At night, or on wet or gloomy days, it is carried away if there be a good quantity of it in the cells usually appropriated to the queen's use for breeding purposes, and removed to the permanent honey stores wherever these may be. In process of transfer the bees reswallow it and disgorge it. All this we know well. I for one believe (and it is at least a reasonable belief), that owing to the heat of the hive a great evaporation takes place in the honey, both when deposited temporarily and when transferred, and that it thickens, and, of course, becomes sweeter and richer in the process of thickening. But do not tell me that the bees have a conjuring power hidden somewhere in their diminutive honey sacs, which are scarcely larger than a big pin's head—a power to convert the watery sugarless juice (according to Mr. Pettigrew), extracted from flowers into real honey by means of the sugar latent in the said tiny sacs.

Now for a bit of real "fact." A friend of mine, who is such an enthusiastic bee-keeper that he can never let bees alone wherever he finds them, tells me that about seven weeks ago, happening to be visiting a lady in Staffordshire who keeps bees, he offered to take her honey for her. This was done, and on carefully examining the combs, which were rich in honey in open cells among the brood as well as in the upper stores of the hive, he could see no difference in the honey. What was in the open cells was just as rich and as perfect honey as that which was sealed-up. He pointed out the circumstance to his hostess in special reference to Mr. Pettigrew's theory, with which he was well acquainted. Now, I do not mean to say that this uniform richness is to be found under all circumstances and in every season alike the same. I know it to be otherwise. But in this instance the bees were still hard at work bringing honey into the hive; and it is a proof of the remarkable productiveness of the season, that quite to the last the honey was as rich or nearly so as it had been at the beginning. There was no crude honey in the hive at all. Can Mr. Pettigrew account for this on his theory? Usually the case is very different. In this country, at least, our honey is uniformly thick and very rich in May. It is gathered from the April and May fruit blossoms, especially from the apple blossoms. In June that gathered from the early white clover is still rich, though paler than that gathered earlier. In the latter part of July and early August it is often very thin and poor with an acid flavour; and at this time, when the honey harvest usually takes place, there will be found all the difference which Mr. Pettigrew describes between his crude syrup in the open cells and the richer honey stored in the upper part of the hive.—B. & W.

## HOW I OBTAINED 131½ LB. OF HONEY IN SUPERS FROM A STOCK OF BEES IN A STRAW SKEP.

THE stock which yielded the honey exhibited I bought, together with three others, at a sale of farm stock, October 29th, 1875. It then weighed about 30 lbs. gross. Early in the spring of this year I intended to have driven out the bees and to have placed them with their comb in a bar-frame hive. During March and April this hive was treated similarly to all my others—namely, fed gently with barleysugar and liberally supplied with artificial pollen. The great benefit arising from this treatment was strikingly shown in this particular hive. It was kept snug and warm, and young bees were being "brushed down" very early whenever there was a gleam of sunshine. The numbers increased daily so rapidly that I had doubts about disturbing the brood comb in transferring to the bar-frame hive. I was advised to let well alone, and to wait until twenty-one days after swarming before I disturbed the combs. Meanwhile to delay swarming a little, and to increase the chance of a very heavy swarm I put on a box of sectional supers on May 24th. This was instantly crowded, and on June 1st was nearly full of comb and honey. It was then that I determined to give additional room, to work as many supers as possible, and to defer transferring until autumn.

I placed another sectional super with a slit in the top under the partly filled one, and June 17th both supers were full and being sealed. Sunday and Monday, June 18th and 19th, were hot and sultry days. A swarming mania seized my apiary. In bar-frame hives I generally prevented swarming, but from the skeps out the bees would come. Among others an enormous

swarm issued from this particular hive, deserting both supers. This was the heaviest swarm I ever saw. While the bees were clustering on a small pear tree I took off the supers, turned up the hive, found that it was full of brood, cut out seven queen cells, placed a Lee's Crystal Palace prize super over the skep, and upon it side by side the deserted sectionals, and on them a Pagden's straw super. I wrapped up all warmly, returned the bees, and in an hour they were working with a will into the four supers. Daily the strength of the hive increased, and on June 24th there was not room for the bees in the hive and supers, for as the bees increased the space was occupied with combs, and nearly a gallon of bees towards evening were clustering outside. I now tried a plan which was most effective. I wedged up the whole from the floorboard a quarter of an inch, and against the side of the hive on a floorboard placed a second straw super. The cluster at once took possession, and for a time every bee was again at work. On the 29th the cluster again began forming, and I then lifted the side super, finding it heavy with comb, and placed a third straw super under it. Here was a combination of the storifying with the collateral system. The desired effect ensued. The six supers were filled with bees. They had bitten an entrance into Lee's super at a projecting corner through thick cardboard (which for the nonce I had employed as an adapting board), so that three streams of workers poured into the pile—one to the mother hive, one to the corner of the projecting super, and one to the side supers. July 3rd I took away two sectional boxes 35 lbs. weight, and replaced them by two similar boxes. Lee's was full and sealed, but I could not remove it, as it formed a foundation to the pile and also gave a high road to the bees without passing through the stock hive. July 14th I took away the third sectional super and put another in its place. This fifth box was not exhibited, being full of comb at the end of the honey harvest, but not sealed. I left home at this period for ten days. Upon my return the honey season had finished, and I removed the three straw supers as exhibited, Lee's Crystal Palace super, and the fourth sectional super. The bees, a numerous colony, with all their combs and a store of honey in dark combs from other skeps I transferred last month into a large bar-frame hive, and up to this date they are being fed gently and are hatching out brood.—P. H. PHILLIPS, *Hitchin*.

### A THEORETICAL NOTION.

THERE has appeared in print more than once a theoretical idea or suggestion resting on the fact that when bees have no brood to nurse they have more time for field labour, and therefore queens should be removed from hives in order to let the bees have more room for honey and time to gather it. If this be done, says an American, hives will be speedily filled with honey. This idea is plausible and easily understood. Is it of any importance or value?

When bees have no young brood to nurse they are, of course, more at liberty for outdoor work; and when they have plenty of sweet empty combs or cells to fill, and none to make, honey is more speedily gathered and stored up. These things are well understood. For instance, if a large swarm be put into a hive full of young empty combs the bees work very fast and gather a great deal of honey on the first four or five days. During this time almost all the bees are at liberty for field work, and often a great accumulation of crude honey is gathered. Presently this honey and the brood of the queen require attention. Indoor duties multiply fast; less outdoor work is done. Again, how often do we witness an increase of activity on the part of field workers after a short season of apparent rest during unfavourable weather. One day of rest seems to recruit the powers of these labourers. In our youthful days we fancied that bees rested and were recruited in strength on wet days in summer. We did not reckon up the unseen duties of home life. Owing to the industrious instincts of the honey bee—gathering honey while the sun shines, the indoor workers are rather heavily taxed, and cannot always store away the honey as fast as it is gathered. The crude honey found in flowers is first deposited in the central combs by the field workers. The removal of this crude honey, the elaborating and perfecting it in their bodies, and afterwards storing it in other parts of the hive, form part of the home duties of bee life. The arrears of indoor work are brought fully up during a season of rest: hence the apparent increase of activity after a rainy day or two.

But the question involved is this, Would the removal of a queen from a hive be an immediate advantage to the bees by making their indoor duties less? Would more honey be gathered? Would a queenless hive without brood collect more stores than one with a queen and an increasing population? There is room enough for doubting here. I have never known a queen removed in order to give the bees liberty for work and room for honey-gathering. Is it possible to believe that the removal or loss of a queen can be of temporary or permanent advantage to a hive? If a stock hive lose its queen before swarming it sustains a severe check and serious loss, and falls far

behind those that retain their queens; and if a first swarm lose its queen shortly after being hived, say within fourteen days, it is all but ruined—at least it can never appear beside one of equal size that has not lost its queen. My experience does not support the theoretical notion of removing queens from hives with a view to obtain more honey. The idea appears to be the outcome of inexperience—a thought that has occurred to some, and not an ascertained fact.—A. PETTIGREW.

### OUR LETTER BOX.

**CORRECTION.**—At page 337, column 1, line 87 from bottom, for "whole" read "old."

**CANTERBURY SHOW.**—We are informed that the first prizes are mostly 30s., and not 20s. as we stated mistakenly.

**JAPANESE SILKIES ROOSTING (Mark).**—We allow all chickens to perch as soon as they are desirous of doing so. We have none but wide perches. The cocks at twelve weeks old show more tail and more comb than the pullets. As a rule they are also larger.

**FEEDING BRAHMAS (Constant Subscriber).**—The only alteration we should make in the dietary scale you give, would be that at night we should be inclined to give soft food, such as meal and sharps well kneaded, instead of hard corn. Of course, much depends on what may be considered as "plenty" of green food, but if the fowls have the run of a garden of half an acre, in which kitchen cultivation is carried on, they should do well under your management.

### REMARKS.

- 11th.—Early morning fine, rest of day very showery; starlight night.  
 12th.—Very fine bright morning, afternoon misty; wet night.  
 13th.—Dark and rainy, heavy at times till 3.45 P.M., then sunny for a little time, afterwards dull again; bright starlight night.  
 14th.—Early morning dull, rain commenced about 10 A.M., and continued for some hours, bright for a short time in afternoon; evening foggy; fine night.  
 15th.—Cooler, but a fine day throughout, with bright sunshine.  
 16th.—Foggy, with rain in first part of morning, bright and sunny afterwards; fine night.  
 17th.—Much warmer, and a very fine day, although slightly hazy.—G. J. SIMONS.

### COVENT GARDEN MARKET.—OCTOBER 18.

THE bulk of common goods has now been sent, and the market consequently begins to assume a bare appearance. The better classes of Apples are now being sought after, and prices are improving. Kent Cobs with a bare supply are realising their full value.

## VIOLETS, AND THEIR CULTURE.

At a time when many are purchasing plants for stock and others making up their Violet beds for the winter, it may not be inopportune to offer a few remarks on the culture of this favourite flower. I am the more induced to do this as, since my notes on Violet odorata pendula appeared on page 298, many correspondents have asked me to give them a few hints on Violet-growing. I have replied to some privately; but within the limits of a letter it is hardly possible to do more than give a few general directions, or even to give them to everyone who asks. I will therefore enter somewhat more into details, premising that I do not write for the skilful in such matters, as many of the readers of "our Journal" must be, but for those to whom a few plain directions will prove acceptable and helpful.

The great mistake with many writers is that they are not explicit enough; they are apt to fancy that nearly everybody knows as much as they do themselves, and are consequently afraid to enter into details which they think are familiar to all. Now I must try and believe, imperfect though my knowledge is, that there are others who are in a still worse plight than myself—people who, though they love Violets, have not the remotest idea how those who grow them successfully and manage to have them for six months of the year, accomplish those results. As far as I know, then, they shall know; and I will promise them that if they attend to my directions they shall meet with a fair share of success.

Everyone, though, is not so advantageously situated as I am. This is a land of Violets. From February to May the hedgerows, copses, lanes, and fields are in many places carpeted with the delicate blossoms of this humble yet precious little gem; while at every roadside you may make sure of gathering a few if you wish. As long as I can remember Violet-picking has been one of my delights; and when absent from dear old Devon nothing ever reminded me so much of home scenes as the sight and perfume of Violets. I quite sympathise with one of my correspondents who writes, "Violets here, alas! are few and far between: when we lived in Devonshire we could get as many as we liked." Well, cheer up, friend; even now if you want Violets, and want them enough to be content to take a little trouble to grow them, this can no doubt be accomplished. Where soil, situation, and climate are propitious, as they are here, some of that trouble may be saved, but not all. Listen, then. If you must have Violets and plenty of them—Violets not only in spring, when they come because they can't help coming, but Violets in autumn and winter too—Violets not for one month of the year only, but for six or seven right away, make up your mind to this: No rough-and-ready or lazy-bed systems will do. There must be strict attention to the following rules, or you will not succeed:—1st, Divide your plants in spring; 2nd, Attend to them in summer; 3rd, Give them room and good quarters in autumn.

No. 818.—VOL. XXXI., NEW SERIES

Now, having impressed these general directions on your memory, follow me while I amplify a little and explain. What do you mean by "divide your plants in spring?" Why, just this: Many people have an idea that the making of a Violet bed is work that has to be done about once in a lifetime. They have but to procure plants, stick them in, and then go on gathering continually year after year. Not long ago a lady said to me, "Violets don't do with us at all, and yet I cannot make it out. The plants seem healthy enough, but we get hardly any flowers. What can it be?" Lazy-bed system, of course, I thought; and so it proved. There they were, all run together into one great mass. Flowers! why, how could they flower? Two or three wretched little blooms might manage to hang themselves out on the edges of the great straggling mass; but whatever superfluous energy the plants had was expended in a nearly hopeless struggle for existence—about twenty crowns competing with each other in every 6 square inches of soil. No, that is not the way to have flowers. If you want your plants to bloom you must at all events give them elbow-room if nothing more.

I will suppose, then, that you have a bed of this description, or plants of some sort run together more or less as they will be by spring, and that April—sunny, rainy, fickle April—has come, and that you have gathered your last Violet. Let this be the beginning of months to you as far as Violets are concerned—a finishing-up of the old year and a coming-in of the new. First you want a new bed and fresh soil to set your infants in. Let it be well worked and aired and liberally manured with either very decayed manure, or, better still, with leaf soil; and if your soil is heavy the addition of a little sand is beneficial. As to situation, I quite agree with Mr. Lee that an open one is the best; but in this you must be somewhat guided by circumstances. If you dwell in a congenial clime where the dry and scorching air of summer is tempered by mild and balmy sea breezes, and where frequent mists roll up from the bosom of the great Atlantic and water the face of the earth, then do as I do—plant your Violets out in a sunny and exposed position, and they will do better than if shaded by trees or drawn-up by hedges. But if, on the other hand, your lot is cast in a dry and thirsty land, where the rays of the sun are powerful and the rainfall is under the average, give the Violets the benefit of a little shade if possible, or the shelter of anything that tends to lessen the excessive evaporation. A border under a hedge (not a wall) facing east is as good a position as can be found.

Having your beds ready, take up your plants and pull them to pieces, planting out each crown separately at distances varying from 6 inches to a foot, according to the variety. The weaker growers, such as the Neapolitan and King, require, of course, less room than such strong sorts as Victoria Regina and Czar. Give the fresh plantation a good watering, to be repeated if the weather is very dry at intervals of a day or two, until you see that the plants are established and your spring work is done. Now do not forget my next admonition. Attend to them

No. 1465.—VOL. LVI., OLD SERIES.

in summer. Summer is a trying time for the Violet. The heavy rains and cold dewy nights of spring and autumn it revels in; winter with its frost and snow it endures with impunity, even the most severe cold only checks it for the time; as soon as the rays of the sun liberate its drooping leaves it is up and growing again. But summer with its scorching sun and drying winds it cannot withstand, and holds out signals of distress; then comes the red spider and adds to its misery. Do not forsake it, then, in its hour of need—no, not even for the Roses. Give it copious artificial showers, and permit no robber from without or within to share the welcome supply—*i.e.*, pull up weeds and remove suckers. You will have your wages paid in full. When the last Rose of summer has faded away, and the dulllest and dreariest part of the year has come, your little friend which you helped in adversity will gladden your heart with grateful blossoms and delightful perfumes. Think of that, and the large watering pot will not seem so heavy.

As the summer draws to a close and the nights become longer and more dewy, if you have attended to my instructions you will perceive a sudden increase of vitality in your Violet beds. Bright green leaves will be thrown up in abundance, and soon you will discern the little flower buds clustering close round the hearts of your plants. Prepare then for a fresh move; for the harvest is near, and almost before you think you will gather the firstfruits. Now is the time to carry out rule No. 3—Give them room and good quarters to bloom in. If you wish to bloom your plants where they stand see that they are not crowded; thin-out if they are, and cut off runners close to the crowns. If you mean to grow some in frames you will of course need a fresh bed. One lady writes me, "I have not met with much success in growing the Neapolitan Violet. Will you kindly give me particular directions how the bed should be made?" To begin with, then, do not trust to your bed. The best of soil will never make your Violets bloom well if they have been neglected previously. Poor, weak, half-starved crowns cannot produce satisfactory flowers, simply because the flowers are not in them, and therefore no bed can get them out of them. A strong healthy crown in September has all its blossoms already stored up in embryo; and the great object of planting the Violets out in blooming beds is that that they may have room to develop themselves, and to allow the cultivator to protect them and to harvest them conveniently and in the best possible condition when they have come to perfection. A suitable soil and a favourable situation are, it is true, great aids. The blooms will be finer, higher coloured, and better shaped, but the foundation must have been laid during the previous spring and summer.

As to the soil, almost any will do that is rich, moderately light, and sweet. Here we have usually planted out the Neapolitans for frame-culture where the ridge Cucumbers or Vegetable Marrows have previously been grown, bringing up and mixing with the surface soil some of the under stratum of decayed manure. In such a soil and in a sunny position Violets thrive admirably. The frames are on from October to April, and plenty of air is given when there is no frost.

As to sorts. If asked to name the three best doubles, distinct colours, I should say, First and foremost *Odorata pendula*, deep mauve, red eye; then *Neapolitan*, lilac, very lovely, large and sweet; *Queen*, large white, usually shaded with purple. This is a fine Violet, but rather uncertain. I have only once succeeded in blooming it well in autumn, and it sometimes fails in spring. Three best singles: First, *Victoria Regina*, out-and-out the best, for which thanks are due to Mr. Lee; colour light bluish-purple. The blooms are very large and well shaped and deliciously sweet. *Czar*, deep purple, good and free. *White Czar*, a stronger-growing variety of the common white hedge Violet; flowers pure white, and very good; but I wait for a better.

We do not find it necessary in this mild climate to give protection to any of the singles in winter; the frames are reserved for the doubles. To the above list of doubles I may add *Marie Louise*. This is a very pure white and quite free from purple shading, and is a very chaste and elegantly shaped flower, and a free bloomer.—R. W. BEACHEY, *Kingskerswell, Devon*.

### THE AIR-TIGHT VINERY.

THE principle on which this vinery has been constructed was and is to stop out all external air, with the exception of the small quantity which might come in through the crevices. I described this house some months since, but as a large crop of

Grapes has been ripened in it this year—*Muscadines* chiefly, but also well-blackened *Hamburgs*—an allusion may be again made to this simple plan of growing Grapes.

In order to ripen a crop of Grapes thoroughly without artificial heat it is necessary to obtain a larger amount of long-continued heat from the sun, and this can only be effected on the bottling-up principle. The exclusion of air, and allowing the temperature to rise to 100°, would in the ordinary house cause total destruction to the crop if this heat without air were continued several hours together. The house I am describing has been built seven or eight years, and not a leaf has been scorched by the sun. There are no ventilators, and the door is never opened excepting when anyone enters, and it is then closed immediately, the principle being never to let out the heat. Anyone going into this house when the sun shines on it fiercely is glad enough to make his escape. The mode of construction is this: Form two flat glazed sides 8 feet in height and any length (this house is only 7 feet), let the width between the flat sides be 8 feet at bottom and 4 feet at the top, the ends to be upright, with a door in each end. This house is to run north and south. The south end is to be whitewashed in summer to prevent red spider. No attention is necessary after thinning the crop, excepting watering the path during the heat of the day. I counted sixty-three bunches on 6 lineal feet of one side. The whole crop was finished a fortnight since, quite ripe and highly flavoured.—OBSERVER.

### PEAS IN 1876.

As Peas are greatly influenced by the weather, I will epitomise it as it has been in "the north." A dull cold spring, the cold reaching its climax in the middle of April with frost (thermometer 15°) and snow. Early summer cold and dry, mid-summer for about a fortnight in July moist, then excessively hot for a month; late summer one continuous term of wet; from the last week in August up to the early part of October there has been but few fine days.

Early Peas have done well. *Unique*, a dwarf kind of about 18 inches in height, gave its first dish on June the 30th. It was very prolific, with the pods well filled. The crop came in all, or very nearly, together. It must take a good place as a market kind.

*William I.* was in at the same time as *Unique*, the last having the benefit of a south wall, which the first had not. It is the very finest of all Peas for earliness, having deep green well-filled pods.

*First and Best* was a few days later, and was more prolific than *William I.*; but white Peas are not cared for when a green Pea is at command. It is, however, the best early kind for general purposes.

*Alpha*, with its large well-filled pods of blue (wrinkled) Peas of exquisite flavour, came next—only a few days after *William I.*, and was good in every respect.

*Dr. Hogg*, of which I had a long row, was excellent; it was quite as early as *Alpha*, and more productive than that kind. The Peas were of a deep green colour and very good.

*Maclean's Dwarf Prolific* (*Prince of Wales*) did not do so well as usual; the pods filled indifferently, and fell a prey to mildew.

*Veitch's Perfection* was better than *Premier*, *Best of All*, *Mammoth Dwarf Marrow* (*Jersey Hero*), and *G. F. Wilson*, which are all of the same type. It was very good, though all these named must be included in that category in a favourable season.

*Dr. Maclean* was superior in productiveness to any other grown this year. It was sown at the same time, but proved a little later than *Dr. Hogg*. It was of excellent quality, and must take a foremost place as a market kind, being probably the best of the Peas of medium height for general purposes. Its productiveness is equal to that of *Fillbasket*, whilst its quality is superior, yet in this respect is not equal to some others.

*Culverwell's Prolific Marrow* withstood the hot weather grandly, giving an abundance of pods well filled with large Peas of superior quality; in that respect I should say it is unequalled, except by *Connoisseur*, which I consider is the best-flavoured Pea in cultivation and the most continuous bearer.

*Ne Plus Ultra* and its dwarf form *Omega* have withstood the continued wet of September and of October well, and yet neither of them has been so good as usual. *Ne Plus Ultra* will, if the weather continue open, keep on bearing for some

time longer; but Omega, which was sown at the same time, is over. As a rule, tall-growing kinds last longer in season than the medium growers.

*Supplanter*, like many others, did not prove entitled to its name, and was not nearly so good as its parent, *Veitch's Perfection*, either in productiveness or quality. It was, however, earlier and had larger pods.

*The Shah* proved to be a very early white wrinkled Pea, extremely prolific and of superior quality. As an early kind for cropping and high quality I consider it excellent.

*Standard* was very prolific, with handsome well-filled pods of nine to eleven Peas in each of a good size and of a deep green colour. Its quality is of the first rank; it is a second early Pea of great promise.

*Marvel* grew very stiff, having very fine pods, well filled with large Peas of an exquisite flavour.

The three last succeeded one another in the order placed from a sowing made at the same time, and they will no doubt bear their mark, as have others of Mr. Laxton's raising.—G. ABBEY.

### SPIRÆA JAPONICA.

As a spring-flowering plant *Spiræa japonica* is well known for its graceful plume-like flowers rising from a bed of shining green foliage, itself a sufficient ornament; but its value as an autumn bloomer is not so fully recognised. At the present time no plant is more striking or more valued for conservatory decoration than this, its chaste flowers associating well with other plants, especially late-flowering *Geraniums* and small plants of *Fuchsias*.

*Spiræas* to flower at the present time should, after the spring blooming is over, be repotted in sandy loam, leaf soil, and a little well-decomposed manure; they may then be given some glass protection, and not, as is so often the case, placed out of doors in the snowy blast to ripen their growth. They should be placed in a position where they can fully develop and mature their growths. During this time they require unfailing supplies of water. Plants standing on a hard bottom and exposed to the sun can hardly have too much water. When settled weather is expected the plants must be taken out of doors, the pots plunged down to the rim in coal ashes, and still kept plentifully supplied with water. When the foliage shows signs of shrivelling give less water, but by no means withhold it altogether. By the beginning of September the plants will again commence growing; the supply of water must then be increased, varying it with weak doses of liquid manure. With good cultural attention plants in 7-inch pots will produce fresh healthy foliage surmounted with twelve to fourteen flower spikes, at a time of year when these charming flowers are not usually seen.—A. W., *Lincoln*.

### SEACOAST VEGETATION.

INJURY BY FROST TO THE POTATO CROP IN W. LANCASHIRE.

NEAR the western edge of the county of Lancashire, and but a very few miles south of the estuary of the Ribble, is a tract of low-lying land that has very likely at one period been covered by the sea, which seems to be still receding from the coast. This tract differs in many respects from the class of lands locally termed *moorlands*, as in its composition it presents fewer traces of decayed vegetable matter than is common with the peat moss, and its specific gravity is much greater. In fact I am not sure but this character of soil presents us with the best example of the prevailing erroneous phrase of designating a sandy soil as a light one, for, bulk for bulk, it is unquestionably one of the heaviest, if not the very heaviest soil we possess. The tract of land to which I refer is composed of a black sand nearly destitute of stones. Such soils no doubt are common on most coasts having a low-lying foreshore, as well as by the sides of tidal rivers near their junction with the ocean. The overflowing of the level space with salt water, and the deposit of sands as well as seaweed and other wreckage for a long period of years, in course of time raise it beyond the reach of tides. This soil is for certain crops eminently fertile, and in the district to which I have called attention it is of great depth, and has been long enough in cultivation to exhibit which crops suit it and which do not prosper so well.

Being, however, placed near the west coast, where the spray from the ocean frequently reaches a good way inland, timber trees of most kinds do not do well, Conifers especially refusing to prosper; but there are plenty of plants of humbler growth which do very well. Notably the Black Currant thrives and

produces finer crops of fruit than is met with in most places where the soil is of an opposite character. Gooseberries, too, are remarkably fine, with trees healthy and free from canker or moss. Strawberries also do well; and amongst vegetables the soil and district is pre-eminently noted for good Celery and Potatoes as well as Carrots and Lettuces.

Peach trees seem to thrive remarkably well; and although finer fruit and better crops of Apples are no doubt produced in districts where the soil is of a different kind, I have never witnessed cleaner and finer-grown trees, not a particle of moss or lichen of any kind being seen on them. This I believe to be due to the sea breezes and saline matter with which the atmosphere at times is charged. Pears in like manner were good, while Raspberries seemed merely to exist. In the flower garden I noticed that *Calceolarias* did not flourish; while, on the other hand, I do not think I ever saw the gold and bronze section of bedding *Geraniums* prosper so well, and many other popular bedding plants were equally at home. With regard to shrubs, *Rhododendrons* were growing remarkably well, but not so the Laurel, Box, and *Laurustinus*, and the *Aucubas* seemed hardly satisfied with their position.

Amongst agricultural crops Oats and Barley were more generally met with in a flourishing state than Wheat. There had been good crops of hay, and in this district the tendency of the soil to produce moss is so great that it is seldom a field laid down as meadow is allowed to remain longer than five or six years, when it is ploughed up, and undergoes a few years of tillage prior to being laid down in grass again.

But one of the most important of all crops in the neighbourhood is the Potato, of which whole fields of great extent are met with, and good crops are produced, and which were free from disease up to the middle of September when I last saw them. But lest our readers elsewhere should envy too much our brethren in the north-west, it is only right to tell them that whole fields embracing many thousands of acres of Potatoes were blackened by frost on the 25th of August, just at the time when the growth was in its most robust condition. A partial recovery took place, but when I saw them about a month afterwards the blackened appearances of the leaves were still visible at a distance. That the crop was injured there can be no question; and although such frosts are not common they are not unknown, they having occurred before about the same period. It is difficult to account for such a phenomenon. The lowness of the situation might have something to do with it, yet there are lower-lying lands around the coast, which are banked out from the water, not so liable as the district in question to suffer from untimely frosts. Possibly, however, some of those in the same or a more northerly latitude may be liable, as it is difficult to assign any reason for the locality here described being alone subject to such a misfortune. Let us hope such visitations as that of the past August are few and far between, and that the fashionable gardening so well carried out in the Botanic Garden and elsewhere in Southport may not receive such a severe check on an unexpected occasion as did the Potato fields a short distance from it.—J. ROBSON.

### OUR BORDER FLOWERS—SNAKEWEEDS.

SNAKEWEED, Knotweed, and other weeds of the *Polygonum* family, are among our neglected border flowers, for seldom do we meet with them in cultivation, and yet they are a very useful race of plants. To see *Polygonum viviparum* in all its beauty moist alpine pastures must be visited. The Teesdale district is one of the habitats where it may be seen in its glory. To see it in perfection the place should be visited during the month of July. It makes a good border plant, and is equally attractive as a pot plant. It requires good drainage, sandy loam, and full exposure. It is useful for exhibition purposes.

*Polygonum bistorta* is at home in moist, shady, or exposed places, and is a pretty plant in early summer. What a beautiful sight to see beds of *Polygonum amphibium* nestling along the banks of the quiet lake, and in many rivers too! *Polygonum vacciniifolium* is a charming evergreen rock plant, but is all the better for a little protection during the cutting winds of spring; its bright shining foliage and pretty rose-coloured flowers have a fine effect. It continues long in bloom; should have good drainage. Loam and sandy peat meet its requirements. *Polygonum sachalinense* (?) is a grand acquisition to the shrubby or large herbaceous border. Let it have room and a good depth of loam to luxuriate in, and it assumes a bush-like appearance when established. *Polygonum brunonis*

is of dwarf evergreen habit, often throwing up its pretty rose-coloured spikes of flowers from early spring to late autumn. *Polygonum amplexicaule* should have a place in all shrubbery and large herbaceous borders; its fine foliage and pretty red flowers are a sufficient recommendation for it. There are several other kinds that are equally attractive and ought to be more frequently met with.

They will thrive in any moderately good garden soil, but are all the better for an admixture of sandy loam or decayed vegetable matter mixed with the soil, which should be broken up to the depth of 18 inches. They are increased by seed sown as soon as ripe, and by division in spring when growth has commenced.—*VERITAS.*

### PREPARING LARGE CONIFERS FOR REMOVAL.

A QUESTION from "AN OLD SUBSCRIBER" has suggested the following:—

Trees that have had their roots undisturbed for a long period of time cannot be removed with safety without previous preparation. With it and the exercise of ordinary care they may be transplanted with perfect success, and in the course of from three to five years they will be growing with as much freedom and vigour as if they had never been disturbed.

During the last four or five years I have annually prepared and removed several large trees of various species, and as the process has been attended with invariable success I cannot do better than describe it. As soon as possible after the growth of the current year is matured and the tree is at rest, the whole of its roots are cut asunder at a certain distance from its stem in proportion to its size, say from 2 to 4 feet. This is done by opening a trench all round it a foot wide and about 2 feet deep, the soil also being loosened beneath the ball, and roots which are found there being also cut through. The trench is then refilled with sound and rather rich soil, the tree secured from damage by wind by having three or four wire stays fastened to its stem, and to stout pegs driven into the ground, and the work of preparation is finished. In the following November, or about a year after the cutting of the roots, a sloping trench is made down to and under the bottom of the ball of earth sufficiently wide for a trolley—really a platform of thick planks upon low broad wheels—to be run under the ball, from the sides of which the soil outside the original trench is then removed, causing the tree to drop gently down upon the trolley, to which horses are then attached and the tree drawn to its new station, planted and made fast with wire stays as before.

It may be well to explain why trees are so treated. When the roots of a large tree are cut off so near to the stem, as they always must be in order to facilitate its removal, it is deprived of almost all its rootlets or feeders by which it obtains nourishment from the soil. The shock to its system is obviously a severe one, so much so that to remove it then would most likely cause it to die. By putting rich soil about the stumps of the roots we induce a rapid and abundant formation of rootlets, so that the tree forms healthy foliage in the following season, although it makes little if any growth in the branches. When the tree is placed on the trolley for removal its ball is a pleasant sight, for it is bristling with rootlets, every one of which is preserved intact with most jealous care; and thus, although there is no appreciable growth for a year or two, yet we know that the tree is sound, that its roots are at work, and that in due course vigorous growth will follow.—*EDWARD LUCKHURST.*

### THE BEST ROSES.

MANY years ago I had a long conversation on Roses with a Cambridge don, and having answered many questions I put one, "Who are the best men in your university?" The reply was, "Ah, that depends upon what you want them for."

I have often thought since that in discussing the merits of Roses, whether in conversation or in print, this fundamental question is often lost sight of. My visitor continued, "One is great in classics, another in mathematics, a third in history, a fourth in physics, a fifth in theology, and so on, and even beyond this one is great in some particular division of these branches of learning and some in another."

Now, it seems to me that it is much the same with Roses, and when I am asked, Which are the best Roses? I reply, It depends upon what you want them for. There are Roses for exhibition, Roses for garden decoration, Roses for cutting for

table decoration, Roses for light dry soils, Roses for heavy moist soils, Roses for wet climates, Roses for dry climates, and so on; and anyone making a selection without knowing the special conditions under which the Roses are to be grown, and the purposes for which they are wanted, is likely to lead those who are seeking information very far astray.

Further, some Roses bloom early, some in mid-season and all at once, others are continually putting forth a few flowers for a lengthened period, and others, again, bloom finely late in the year. These latter have always possessed great charms for me, and I have consequently preserved and cultivated such assiduously. How delightful, when all the summer-flowering plants are spoilt by the frost, to find in one's garden red, purple, white, and yellow Roses. How sweet they are, and almost as fine as in summer!

In confirmation of the assertion that there are such, I transmit you a bouquet. Although I would be cautious in saying that they are the best, I am prepared to say that they are among the best of the very late autumn-flowering kinds. They were cut this morning (October 24th), and in fine seasons I have often cut flowers nearly equal in size and symmetry, and superior in colour, a month later. Here are their names:—

*Hybrid Perpetuals.*—Marquise de Castellane, Countess of Oxford, Madame C. Craplet, La Reine, Monsieur Noman, Marie Baumann, Dupuy Jamain, Madame Victor Verdier, Madame Caillat, François Fontaine, and Princess Beatrice.

*Teas.*—Madame de St. Joseph, Gloire de Dijon, Madame Tride, Souvenir d'un Ami, and Madame Falcot.

*Bourbons.*—Comtesse de Rocquigny, and Souvenir de la Malmaison.

In addition to these I have three China Roses—Cramoie Supérieure (crimson), Fabvier (crimson), and Mrs. Bosanquet (blush), covered with masses of buds and flowers. These latter are of course out of court as exhibition Roses, and hardly fitted for table decoration, but for the garden nothing can be more effective, nothing more lovely. What a deal they lose who go in for a limited number of varieties, especially where a garden is of large size; it is like living on beef and mutton only.—*WILLIAM PAUL, Paul's Nurseries, Waltham Cross.*

[The Roses received were superior blooms, and sustain all that Mr. Paul has said of them as being "sweet and almost as fine as in summer."—*EDS.*]

### THE ROSE ELECTION.

I HAVE already on the spur of the moment said a few words in reply to "WYLD SAVAGE," but often words, even when answered, have the power of leaving a mark behind; so have they in the present case. "WYLD SAVAGE" administered some advice without assisting me to follow it. He said, "What Mr. Hinton should aim at is securing the opinion of the leading nurserymen and those amateurs alone who have distinguished themselves at the London or large provincial shows." Now, as some answer to this, out of the forty-seven electors I have ventured to select nine from each section as persons thoroughly qualified to elect the best Roses. They are names that have appeared in the prize lists either of the metropolitan or large provincial Rose shows, with the exception, so far as I know, of Mr. Rumsey; but his very long connection with the Paul family, as foreman I believe, must make him fully qualified to give an opinion, and I herewith present our readers with another list selected by these eighteen voters. The voters I have selected are the following—viz., Revs. C. P. Peach, Dombrain, J. B. Camm, and A. Cheales; Messrs. Beachey, Laxton, Scott, Wootten, and Captain Christy among amateurs; and amongst nurserymen Messrs. Cranston, Curtis, Cant, Davison, G. Paul, G. Prince, Rumsey, Turner, and Walters. There are perhaps several others who have equal right to be considered successful exhibitors, and I must apologise to them for omitting them. The names above, it seems to me, ought to carry weight. Does the result of the scrutiny of these votes proclaim the election list as already declared, to be "a mockery, delusion, and snare?" Does the list I append prove the correctness of "WYLD SAVAGE'S" anathema? Does it stamp the election as already given as "a miserable, misleading, unrighteous, abominable election?" I think the reply to all these questions is distinctly in the negative.

Supposing a beginner looking at the previous list decided on investing in the first fifty, how far does this fresh list below prove that he has been misled and that he is investing in inferior sorts? Tried by this fresh test what alterations do we find? Why, the very same Roses are in the fifty with the

exception of three! Abel Grand, No. 47, Madame Willermoz, No. 48, and Annie Wood, No. 50, are replaced by Annie Laxton, Cheesnut Hybrid, and Mons. Noman. I allow that a great many of the others are in different positions, but a first or second-class vote more or less makes a vast change in the position of the list, as "WYLD SAVAGE" would soon find if he altered half a dozen. The fact remains that the best fifty are very nearly the same. The list runs thus—

		A	B	C	A*B*C*	Total		
1	Maréchal Niel	9	0	9	9	0	9	18
to 4	Alfred Colomb	9	0	9	9	0	9	18
	Marie Baumann	9	0	9	9	0	9	18
	Baronne de Rothschild	9	0	9	9	0	9	18
5	Charles Lefebvre	9	0	9	8	1	9	18
6	Etienne Levet	8	1	9	8	1	9	18
7	La France	8	1	9	7	2	9	18
8	Louis Van Houtte	7	2	9	7	2	9	18
9	Marquise de Castellane	8	1	9	6	2	8	17
10	Duke of Edinburgh	5	3	8	4	5	9	17
11	Madame Victor Verdier	3	5	8	5	4	9	17
12	Comtesse d'Oxford	4	5	9	3	5	8	17
13	John Hopper	3	5	8	3	5	8	16
14	Devoniensis	4	4	8	5	2	7	15
15	Catherine Mermet	4	3	7	4	4	7	15
16	Sénateur Vaisse	2	6	8	2	6	8	15
17	Xavier Olibo	2	5	7	2	6	8	15
18	François Michelin	5	1	6	7	1	8	14
19	Horace Vernet	2	5	7	4	3	7	14
20	Mdlle. Eugénie Verdier	2	6	8	3	3	6	14
21	Mdlle. Marie Rady	3	5	7	1	6	7	14
22	Gloire de Dijon	3	3	6	5	2	7	13
Eq.	Dr. Andry	5	8	8	1	4	5	13
	Marguerite de St. Amand	2	3	5	4	4	8	13
Eq.	Pierre Notting	4	3	7	1	5	6	13
	Emilie Haussburg	3	4	7	2	4	6	13
27	Duke of Wellington	2	6	8	1	4	5	13
28	Fisher Holmes	2	4	6	0	7	7	13
29	Souvenir d'un Ami	4	4	8	2	2	4	12
Equal	Prince Camille de Rohan	1	5	6	3	3	6	12
	Souvenir d'Elise	2	5	7	2	3	5	12
23	Camille Bernardin	2	5	7	2	3	5	12
24	Madame Lacharme	1	5	6	2	4	6	12
25	Ferdinand de Lesseps	4	1	5	4	2	6	11
36	Dupuy Jamain	6	1	7	0	4	4	11
35	Marie Van Houtte	2	2	4	2	5	7	11
37	Victor Verdier	1	7	8	0	3	3	11
38	Captaine Christy	1	3	4	0	6	6	10
39	Mdlle. Marie Gointet	0	6	6	0	4	4	10
Eq.	Reynolds Hole	1	4	5	2	2	4	9
Eq.	Comtesse de Serenyi	2	1	3	1	5	6	9
	Madame C. Wood	0	4	4	2	3	5	9
44	Niphotos	1	3	4	1	4	5	9
45	Annie Laxton	1	4	5	0	4	4	9
46	Edward Morren	2	2	4	1	3	4	8
47	Mdlle. Marie Finger	0	4	4	2	2	4	8
48	Maurice Bernardin	0	4	4	0	4	4	8
49	Cheeshunt Hybrid	3	2	5	1	1	2	7
50	Souvenir de la Malmaison	0	1	1	3	3	6	7
51	Monsieur Noman	0	1	1	2	4	6	7
Eq.	Abel Grand	0	4	4	1	2	3	7
52	Duchesse de Caylus	1	3	4	0	3	3	7
53	Annie Wood	0	5	5	0	2	2	7
54	Madame Willermoz	0	2	2	0	4	4	6
Eq.	Paul Neron	0	3	3	0	3	8	6
	Star of Waltham	0	3	3	0	3	3	6

It is very certain that in this list François Michelin, for instance, is much lower, though tried by first-class votes it would revert to its old place; but the Tea Roses, especially Catherine Mermet and Marie Van Houtte, have risen considerably; but this is to be expected, for more decidedly exhibiting Rose-growers would sacrifice something to grow these Roses, willingly taking the extra care that they require. Star of Waltham takes a great leap, but with such electors the good new varieties would probably obtain notice. I make this further remark, that Paul Neron has completely outstripped his companion Belle Lyonnaise, which polls only three votes, in spite of "WYLD SAVAGE's" praise, whilst Beauty of Waltham only reaches the same number.

If able to undertake the election another year I propose to make it more decidedly an "exhibiting" election, as this may be useful, but the present election never professed to be that. —JOSEPH HINTON, Warminster.

WHATEVER may be my opinion as to the result of the election, there can be but one as to the feeling which all rosarians have towards you (Mr. Hinton), and that is gratitude. Deeply grateful are we all to you for the great trouble you have taken in conducting this election, and only the excitement consequent upon reading the results caused even a "WYLD SAVAGE" of the woods to forget to thank you.

Although I do not know much about the Wiltshire spring breezes I am intimately acquainted with sou'-westers from the

English Channel, which are, I should say, much like those from the downs near Warminster. Certainly I live in a very wild country indeed, and one the soil of which is a byword—an apology indeed for soil, so that I do not think there is much difference in my climate and my friend Mr. Hinton's, for I know the returning officer very well, and am surprised he does not recognise me.

Yet, although I grieve to think I have in any way hurt Mr. Hinton's feelings, I must stick to my opinion as to the returns.

Mr. Hinton speaks of that gem of the purest water Marie Van Houtte as if it were a sweet pretty little Banksian or Rose de Meaux. Here, and at Exeter, it is often as large as at all events Mr. Hinton's pet the "Gloire," and often it may be placed in the back row of an exhibition stand, and if that does not make it a grand Rose what the word grand means is unknown to—A WYLD SAVAGE.

I HAVE had a very good season under the circumstances, but I have taken Mr. Baker's advice and have grubbed-up 450 plants that have done good service, and replaced them at the price of £2 and £2 5s. per hundred. I see occasionally objections to my statements in respect of Roses, and I am sure that I do not object to them. I know that circumstances, such as soil, aspect, and culture are so different that we cannot all agree; but I must protest against an objector to my statements forgetting that I am a gentleman. I trust I have never written a discourteous article, nor expressed myself in respect of other people's articles in a way that, upon maturer reflection, would cause me deep pain.

I thank Mr. Hinton (though I did not join the election, for the reasons given to him privately) for his most able account of the election. I thought the placing of Comtesse de Chabrilant, confessedly one of the most beautiful and best-formed Roses, so low as 81, with only eight votes and no first-class votes among the nurserymen, as one of the mysteries of elections. I am sure I only express the mind of the whole Rose world when I say how much we all owe to Mr. Hinton for his able and valuable labours.

P.S.—Baronne Prevost was raised by Desprez, and not by Laffay, as stated by me.—W. F. RADCLIFFE.

EVEN a worm will turn, even "chaff" will fly up occasionally, and I must say a word on "WYLD SAVAGE's" letter. Poor, dear, old Die-John, to think of anyone calling him an impostor, the "greatest impostor out;" and this to be all the thanks which that public benefactor, Mr. Hinton, gets for his most laborious and admirably executed election work. If this letter leads to more of "the giants" sending lists on another occasion, so far good will have come of it. It is greatly to be desired that we should have the opinion of more of those who are best qualified to form one. I venture to think also that the list would be made more interesting if the Roses were classed in the estimated order of merit, and not some of them alphabetically. But I took up my pen through amazement at the disrespect such an authority as "WYLD SAVAGE" (if I interpret the "Wyld" rightly) should have shown to the estimable parent of Madame Berard and Belle Lyonnaise. Certainly Gloire de Dijon is seldom seen in the "box," because seldom carefully cultivated; but, as somebody said in our Journal, if restricted to one Rose I would say, Give me good old "Glory." He is good all round, and all the year round. The following fact respecting him speaks for itself. At the Reigate Show in 1874 (and Reigate can grow Roses) the silver challenge cup for the best twelve Roses was taken by a box of Gloire de Dijon, while also one of the Roses in the very same box was pronounced "the best Rose in the Show," Messrs. G. Paul, Mitchell, and Francis being judges.—A. C. Brockham.

LET me add a few words to Mr. Hinton's reply to "WYLD SAVAGE" with regard to the Rose election. Mr. Hinton is quite right in saying that it was never intended only to elicit the opinions of professional Rose-growers or of amateur exhibitors as to the best exhibition Roses. My idea with regard to the election was that each person should say what Roses, as a general rule, did best with him in his own garden under his own supervision, and which flowered freely, holding always as a standard that the blooms should be of good shape and size—not rough, flat, or small. If I lived in the sunny south and had a warm border with plenty of rich soil and farmyard manure, and means of protection in the winter, no doubt I should put Marie Van Houtte and Souvenir d'Elise, and perhaps La Boule d'Or, into the first twenty; or had I been

thinking only of exhibition blooms, such as I had noted when judging, I should not have put Dupuy Jamain, or Antoine Ducher, or Comtesse de Chabrilant, or even Fisher Holmes, into my list.

I think (but am not quite sure) that "WYLD SAVAGE" was at Birmingham when Dupuy Jamain carried off the prize (at the time when the Royal Horticultural Society held their show at Birmingham) for the best twelve blooms of any one kind, and in my opinion as a judge I never saw twelve more beautiful Roses staged, glowing in colour, and excellent in shape and form. But then Dupuy Jamain will not stand a warm climate or thin soil, and it requires very close pruning and good management; and I fancy the warm climate of the south, and especially such a summer as we have had this year, would, as "WYLD SAVAGE" says, "give Dupuy Jamain as many petals as a Horse Daisy;" but I can assure him that with me there are few Roses that give better blooms, though if I had to exhibit I should be very careful not to put a fully-opened one into my stand on a hot morning in July. I quite endorse what he says about such Roses as Madame Chirard or Baron Chaurand; but then there are some persons who like small dark Roses; others who like good flat blooms, like Baronne Prévost, or Thomas Rivers, or Thyra Hammerick, &c. Others, again, cannot afford space of ground, or the cost of growing and trying all the best new Roses as they come out, so that many of the more recently introduced high-class Roses take some time before they come into a list such as the one which Mr. Hinton has with such time and trouble collected.

I think it would be quite worth while to select six amateurs and six nurserymen, accustomed to exhibit and grow Roses, to give a list of exhibition sorts. I would not choose merely judges, for many of the best judges of Roses cannot always afford to grow enough varieties or even enough of each variety to have every Rose practically under their own eyes; and I equally know many nurserymen who grow Roses in great quantities who are yet not qualified to judge a stand of seventy-two varieties. The best growers, in other words, are not always the best judges. If I might make the suggestion, I should like "WYLD SAVAGE," "Hercules," and the Rev. S. Reynolds Hole to select six amateurs and six nurserymen to give the lists, and I am inclined to think that at least thirty-six out of the fifty named in Mr. Hinton's election would still be placed in the fifty exhibition Roses.

With me Belle Lyonnaise is no better than her mother, and the "fat, fair, and forty" is quite as good as the blushing maiden. She has, perhaps, a more delicate shade of yellow; but though the old "Gloire" very often gives us rough flat Roses, what Rose is there, except, perhaps, La France, that one can often cut to put on one's drawing-room table? and early and late in the season the blooms are often perfect. I again aver that I do not believe Gloire de Dijon is a Tea, but a hybrid between a Tea and a Bourbon; and I should like to know other rosarians' opinions on the subject.

There are a great many exhibition Roses, as Duc de Rohan, Beauty of Waltham, Duke of Edinburgh, and others I could mention, that do not seem to thrive in cold climates. Nothing seems to me more capricious than the constitutions of some Roses. Many seem to deteriorate the more they are propagated and the further removed they are from the seedling. Roses which seem when first shown as recent introductions to promise well often fail to make their way in the Rose world. There are other sorts, again, which improve by constant cultivation, just as some kinds of Apples and Pears can be improved by grafting and re-grafting. I am confident, too, that the constitutions of some Roses have been impaired by constantly budding on standards planted in nursery rows—long, bare, dried-up stems with very few roots, and then the buds are taken again from these; when nurserymen want to increase a stock of Roses of any kind quickly they are not very particular as to buds.

I omitted this year in my list Duke of Edinburgh, because, though I have occasionally seen magnificent blooms, and beautiful in point of colour, it nearly always quarters, and for one good bloom I cut ten which are indifferent. There are some Roses, too, like Marquise de Mortemart and the old Madame Furtado, which are only good in some soils and occasional seasons. Madame Furtado I fear will soon be a "thing of the past." I see it disappearing from nurserymen's lists, and yet I have a lively recollection of a box of twelve blooms that I cut from the vicar of Cauntun's garden and exhibited at Newark, and which I have hardly ever seen surpassed. I put Thomas Methven in my list this year because I have

had some wonderfully fine blooms this summer, with more substance of petal and more lasting than any Rose I almost ever cut. I have been obliged to discard Monsieur Noman, though there is no more beautiful pink Rose under glass or in fine weather; but the quality of the petal is so flimsy that the least rain or damp glues the buds up so that they cannot open. I fancy Monsieur Noman would do best on a south border, where it could have plenty of sun and air, and yet be protected from north and east winds.

Having entered on the subject of Roses I find I have wandered from my text, which was to back up Mr. Hinton against "WYLD SAVAGE;" not but that I have a certain degree of fellow feeling for the "Savage" if he thought the list was to be made only with reference to the exhibition table when he saw some of his favourite Teas degraded; and certainly in some of the lists (and as there are a great number I need not be personal) there is a wide variety of taste displayed—"Everyone to his own taste," as the old woman said when she kissed her donkey—and I am convinced that this list of Roses will help many persons to form their judgments as to the Roses best suited for their own gardens or in their own neighbourhood.—C. P. P.

### TROPÆOLUM SPECIOSUM.

RELATIVE to the hardiness of *Tropæolum speciosum*, noticed by "A RAMBLER" in the Journal of the 5th inst., for upwards of twenty years I had grown it as an herbaceous plant, and as such have exhibited it at gardening competitions with success. So freely does it grow with me, that a narrow border along a wall, up which it climbs on trellises (cords do well for the purpose) and flowers profusely, is literally matted with rootlets. When once fairly established it is not easily destroyed; but few real florists I should think would care for parting with such a gem. The severest winters have never done the plants any injury, and if protected with a few Spruce branches the old shoots remain active during winter, and push forth flowers early in the season. From the month of May to November the rich scarlet flowers produced a blaze of beauty unequalled by any other climber. I have had it growing among shrubs, and the plants rambling over evergreen bushes have produced a brilliant effect among the green leaves. At present *Tropæolum speciosum* is in perfection, and one of my brightest floral ornaments.—THOMAS NICOL, Balgonie, Fifeshire.

### NURSERYMEN'S VOTES IN ELECTION OF ROSES.

Mr. B. CANT, St. John Street Nursery, Colchester.

CRAWFORD'S EARLY PEACH.—Mr. Burnett of The Deepdene, Dorking, writes to us as follows on Crawford's Early Peach:—

"I have had a rather longer experience of this Peach than your correspondent Mr. Taylor, and though with me it has been satisfactory as a good cropper, and generally swelling out its fruit well, I could not recommend it to anyone whose wall space is limited, but if room can be spared for a tree it is worth its room for the sake of a few splendid-coloured fruit, though but second-rate in flavour."

### JUDGING VEGETABLES.

THERE can be no harm in eliciting the opinions of correspondents as to the relative value one vegetable may be supposed to have over another in collections; but I am afraid after all, judges will act on their own individual opinions, and award the prizes to the collections having the greatest general merit, irrespective of what they are composed. In some instances it may be right to give a point more to Potatoes than Tomatoes, but in the majority of instances it is likely to be wrong. To assume, as Mr. Fairweather does, that Potatoes should, whatever their merit, have priority of place in collections because these are of "the utmost importance and value to all," is about as weak an argument as could be produced. As well allow a dish of culinary Apples to usurp the place of a Pine Apple, or a dish of Muscat Grapes, in a collection of fruits.

I believe I was "one of the Judges" at the "local show" alluded to by Mr. Fairweather, where I and my fellow Judges had small difficulty in determining betwixt the rival collections, despite the circumstance that the first and second-prize collections contained Tomatoes, Vegetable Marrows, and Cucumbers, which Mr. Fairweather is pleased to state "were of no great merit," though in the opinions of the three Judges they were considered of fair average merit. The commended lot, which according to Mr. Fairweather contained such "superior examples" of Potatoes, Peas, and Cauliflowers, belonged to himself, which circumstance may account for his surprise at the Judges arriving "at such a conclusion."—JAS. ADAMSON, *The Gardens, Brynkinlalt.*

### EARLY APPLES—ROSES—UMBRELLA PINE.

I, as well as many others, have been perusing the interesting discussion in your pages about early Apples. I am somewhat surprised that more prominence has not been given to that very excellent early dessert Apple called the Arbroath Pippin, a synonym of which is the Oslin Apple. I have to endorse what one of your correspondents says about the Quarrenden, which is described by everyone else as being highly ornamental and of delicious flavour. Now, I quite agree in thinking its appearance is handsome; but here the fruit is uneatable excepting when cooked, and by no means first-rate when forming part of a tart or pudding. I should like to hear more about the Domino Apple. I have found in an old fruit manual an Apple called Dominiska, but the latter is not an early Apple, nor does it otherwise answer to the description of Domino.

I have had some magnificent Peaches of Crawford's Early this year, and as good as they were handsome, so that I can fully corroborate the account given in your journal.

Among the Roses I see no mention of a very old-fashioned one called Pierre de St. Cyr, one I should not like to be without. Its size is not large, but it is well formed, flowers in large clusters, will grow in almost any soil; its colour is lovely, it is deliciously perfumed, and blooms later I believe than any other Rose.

Will you kindly tell me what is the name of the Pine which we see in the neighbourhood of Rome and Naples, with a tall stem and spreading top? I have heard it called the Umbrella Pine, but no doubt it has some specific botanical name. Would that Pine stand an English winter?—C. R.

[*Sciadopytis verticillata* is the Umbrella or Parasol Pine. It is a native of Japan, and hardy.—Eps.]

### MARTYNIA DIANDRA.

SOMETHING more than ordinary care is required to cultivate successfully the family of plants our figure represents. These beautiful plants are met with in various parts of the world, and many years have passed since some of them were introduced to our notice. *Martynia diandra* is said to be from new Spain, others are from Mexico, the Cape, and America, all requiring the same treatment, and are what are termed stove

annuals. The seed requires sowing in early spring in well-drained pots, in soil composed of sandy loam and peat in equal quantities, with a little leaf soil, charcoal dust, and silver sand. The soil in the seed pots should be made moderately firm before sowing, covering the seed lightly, pressing it down, and plunging the pots in a brisk bottom heat. As soon as the plants make their appearance they should be gradually exposed to the atmosphere of the house, taking care at all times to shield them from cold draughts, which are very injurious to them. When large enough to handle they should be potted-off into small pots, singly or two or three in a pot as may be thought desirable. They should be plunged after potting in

Fig. 52.—*Martynia diandra*.

bottom heat, and potted-on as they may require while progressing. They require a humid atmosphere to hold in check red spider and thrips. When the flowers appear the plants may be hardened-off and placed in a cool stove or warm greenhouse, and they will repay any amount of labour bestowed upon them.—N.

### TOMATOES DISEASED—PACKING FRUIT.

I HAVE observed in two or three late numbers of the Journal communications relative to the appearance of the Potato disease among Tomatoes. The experience of your correspondents varied. It may, therefore, be useful to give my experience also.

For several years I have grown Tomatoes in a cool vinery, and most prolific have they proved when so grown. I am satisfied that one year I gathered a bushel of fine fruit from each plant. The plants were allowed to grow without stopping, and on an average covered a space about 6 feet by 8. Last year (1875) I raised but two plants, judging they would suffice to supply my table, and doubting whether too many Tomatoes did not rob the vines. But in the autumn, I think in September, both the plants and their fruit suddenly turned black, and both my gardener and myself recognised the Potato disease, or what exactly resembled it. The plants were destroyed, but much of the fruit ripened on the shelves. Now comes the point of my story. There were no Potatoes in the neighbourhood; I had grown some of the early kinds, but they had long been dug up and eaten, therefore the Tomatoes had not taken the disease by infection. Another of your correspondents is at fault in supposing that growing Tomatoes under glass would effectually protect them.

While I have my pen in hand I should like to give my fellow gardeners a wrinkle touching the packing of fruit. I had been

at a loss, and found cotton wool answer only moderately well. Wishing this year to send some fine Peaches by rail to a distance, it occurred to me that the spray of Asparagus might answer my purpose. It did answer thoroughly, and I have since sent Figs and Grapes by rail packed in the same way. The recipient reported the Figs as fresh as if just gathered, and the Grapes without the loss of a particle of bloom. The spray of the Asparagus is of a dry nature and elastic, keeping fresh, moreover, for some time.—C. A. B.

THE question of diseased Tomatoes raised by Mr. Boyle, arising from Mr. Moorman's article on this most useful esculent, induces me to give my experience with reference to the matter.

In 1845, the year the Potato blight first made its appearance I saw many Tomatoes diseased, more especially on the plants which were in shaded or damp situations. My father, who was at that time a grower for market, remarked he had never seen anything of the kind before, and, from its general appearance and the affinity of the Tomato to the Potato, considered it one and the same disease. When there ought to have been bushels there were hardly dozens of Tomatoes fit for market. The following year they were again diseased, but not to the same extent (the summer being drier) as in the previous year.

For many years I have observed the disease more or less, and to insure immunity from it have endeavoured to have my plants as forward as possible, so that the fruit perfected itself before the dull and wet weather of autumn. If possible I like to have the blossom set before planting out. When I had the means I grew some in pots in the Pine stove or vineries, so as to ripen in June when they were much appreciated.

My experience tells me that Tomatoes are as liable to disease when far removed from Potatoes as when in proximity to them, as on the first appearance of the disease some of the plants affected were far removed, no Potatoes being within 50 yards of the Tomato plants, and this year I have some disease at the east end of a south border, which is now partly shaded by a plantation, and 60 yards from where any Potatoes were grown; while at the other end with a 12-feet border, and a 6-feet path separating them from a plot of Potatoes taken up in August, no disease is visible. Evidently the disease is one and the same on the Potato and Tomato.

While writing about Tomatoes I would say to those who have never tried them, that small green Tomatoes are a good substitute for green Gooseberries in either tarts or puddings, and I say try them.—J. GADD, *Thorndon Hall*.

In the wet season of 1872 I had some Orangefield Tomatoes planted in an open space in the garden and trained to stakes; not far from the Tomatoes was a large plot of Potatoes, and both the Potatoes and the Tomatoes were ruined by the disease. During the same year I had other Tomatoes trained to a south wall, the border in front of which had produced early Potatoes, which were dug up before the murrain set in. The Potatoes on this border were scarcely affected with the disease. I do not, however, consider that the Orangefield Tomatoes in the open garden "took" the disease from the Potatoes, or that the Tomatoes on the south border escaped the disease because of the early digging-up of the Potatoes from the same border. The south wall had a broad coping, which sheltered much wet from the Tomatoes, while those in the open were exposed to the deluge. In my experience both Potatoes and Tomatoes are liable to the same disease if long exposed to heavy rains accompanied with a high temperature producing what is known as "muggy" weather. The disease of one of the Solanums named does not "take it" from the other, but it is engendered in either of them separately under the conditions named.—W. B. J.

### DECIDUOUS TREES AND SHRUBS.

PLANTERS for ornament make choice principally of Conifers and evergreen shrubs. In most instances these have foliage in various shades of green, though some are enlivened by gold or silver variegation, and others are ornamental from the profusion of their flowers. Evergreens have a sombre and monotonous aspect, especially in winter, whilst at all times they are dense and formal, and are suggestive of warmth, shelter, and repose. Deciduous trees and shrubs have in winter a dreary aspect, but even when leafless there is so

much lightness and grace in the disposition of their twigs, which, seen in conjunction with the noble trunks and massive arms, render them objects of admiration. Both evergreens and deciduous trees have claims upon the planter of an associate character. It is in winter when the trees are leafless that the Ivy encircling their stems and clothing their branches with the deepest of green foliage is most conspicuous, and that the Holly, covered with its scarlet berries, is most attractive. Evergreens, varied as they are, have a greater fixity of aspect than that presented by deciduous trees. If we except a few of the most prominent flowering evergreen shrubs, as Rhododendrons, Berberies, Laurustinuses, &c., a garden or pleasure ground mainly comprising evergreen trees and shrubs is much more barren of interest than one including deciduous trees, excepting during the winter, and even then there is often more to be said in favour of the deciduous trees than evergreens, for no grander sight is presented than a deciduous tree hung with snow, the trunk, limbs, and twigs supporting Nature's brightest crystals. Compare in mid-winter the giant of the Sierra Nevada, the pride of the Andes, and the Glory of Lebanon with the majestic Oak, the elegant Birch, and graceful Willow. There is a beauty in all, but I consider that evergreens in snowy weather are less attractive than deciduous trees.

As further elements of beauty in deciduous trees, the delicate tint of the early leafage, the blossoming, the full summer foliage, the rich autumn tints, and the fruit, are each in turn pleasing, if from no other cause than variation—change—one feature succeeding another, for scenery without variation must fail to please for any lengthened time. Variety, however, is not to be supposed as resulting from groups of trees or shrubs arranged without design. When a plantation must necessarily comprise but a few species it is preferable to form them into masses rather than to seek variety by planting a group in dots of one species; nevertheless, by planting groups of five trees we give distinctness, and by planting other groups at intervals, increasing their size as the view recedes, we produce a very agreeable effect. Distinct groups of trees have not the monotonous aspect of plantations made to appear without design by extremely diversified planting.

The foliage in all masses of trees and shrubs being much more abundant than the flowers, except in a few instances, the arrangement ought to be guided more by the colour of the foliage than by the colour of the flowers; but in arrangements of flowering shrubs or trees we must not oppose the pink of the Crab to the white foliage of the Populus alba, or the gold of the Furze to the Dogwood. They do not associate in colour, nor are they allied. The Crab and Furze are found in nature in a different kind of surface or soil to the White Poplar and Dogwood. No greater mistake is committed than seeking for beauty by planting trees in soils and situations altogether unfit for them. Of this fancied beauty is the mixing of trees and shrubs in shrubberies, and the scattering of them singly on lawns, which only tends to produce intricacy and variety by anomalous forms. Intricacy when produced by objects of the greatest simplicity is agreeable and satisfactory, but to produce intricacy by an endless number of regular forms is incongruous. Irregular and regular shapes mixed together are generally unsatisfactory, and none more so than the irregular planting of trees and shrubs on lawns without any regard to relation or order. The mixing of flower beds with groups or isolated shrubs or trees on lawns is one of the most common of errors in ornamental gardening. The one injures the effect of the other, for however picturesque it may be to see trees, shrubs, and flowers struggling together in natural scenery, the object of collecting trees, shrubs, and flowers is that they may be displayed to greater advantage, and to do this they must have conditions favourable to their production in the highest excellence. No shrub attains to anything like the superiority under a tree as that of a similar shrub in the open. No herbaceous plant shaded by trees or shrubs, or the soil penetrated by their roots, will arrive at the fullest beauty; and in shrubberies or mixed clumps plants of an herbaceous kind are kept from arriving at perfection. Ligneous and herbaceous plants are of an entirely different character. The beauty of an herbaceous plant is its habit and the colour of its flowers. To enjoy it, it must be near the eye. The expression of a tree is stateliness and dignity, and to take it in its full proportions the eye must be at a certain distance from it. By placing flowering plants in the foreground of shrubberies we may be said to derive the expression of both. Admitting this, it is still clear that the two

expressions do not harmonise (the flowers in the foreground derogate from the expression of the trees), and their discordancy ought to prevent their being planted together.

If trees and shrubs or shrubs and flowers are to be exhibited on the same lawn they will always be most effective when displayed in separate beds, the trees being planted in the background or point most distant from the eye, the shrubs in the mid-distance, with the flower beds in the foreground, grouping each by themselves. In this manner the inconsistency of mixing trees and shrubs together would be avoided. Another very desirable mode of introducing beds and borders of flowers is to enclose an open space with shrubs. Evergreens are generally chosen of such a kind as naturally grow compact or that admit of being cut into shape. It is considered that dark and shining foliage, as that of the Yew, Holly, Laurel, and Rhododendron, form the best of foils to masses of colour. It would be absurd to form an outline of coloured-leaved shrubs in accord with the colours of the flower beds, and equally absurd would be an outline to such a garden of flowering shrubs, for the latter would derogate from the beauty of the principal object in view. As to the form of the outline or screen, if the outline of the beds for flowers be scrolls—regular, or symmetrical, or geometrical—the outline of the shrubs will best accord by being kept formal and regular; but if the beds are of irregular forms at irregular distances, the shrubs surrounding must be allowed to assume more of their natural forms.

It does not of necessity follow that we must not employ evergreens with deciduous trees. Naturally we have Ivy, Holly, and Spurge Laurel, springing up simultaneously with deciduous trees in our own country. This kind of undergrowth we may, in either evergreen or deciduous shrubs, imitate; but the trees should predominate. We must not, however, plant trees and shrubs together with a view to exhibit them in the fullest excellence. If we introduce evergreens at all we must make choice of such as thrive fairly in the shade, and to effect this it is important that the shrubs and trees are planted at the same time, so that they may grow up together. When this is attended to there will not be any difficulty in securing an undergrowth of evergreens; but when it is neglected there is much difficulty, from the pre-occupation of the soil by the roots of the trees, in establishing shrubs beneath them.

In the arrangement of trees and shrubs the trees should be at the point most distant from the eye, whether they be evergreen or deciduous; and if we must of necessity employ both in the same arrangement, I should plant the most light, ornamental, and flowering shrubs where they would just be seen amongst and through the interstices of the evergreens, in such a way as to display their foliage and flowers to the eye of the spectator. Evergreens as a rule should preponderate near the residence, and by judiciously employing variegated kinds much would be added in giving variety, especially in winter. I do not mean that the mansion should be encased by evergreens as were monasteries by Yews, but employing such as are of low growth, so as not to interfere with the architectural effect, when they are seen at a distance, in connection with the building; and I should employ principally evergreens in what may be termed the boundary of the lawn, and keep that as open as practicable, for upon the distinctness of the foreground will depend the beauty of the objects beyond. Upon the lawn should be no closely-planted masses, and few isolated trees or shrubs, as they tend to diminish the apparent space from every point of view.

In the foreground of course will be flowers, but I have said so much upon this subject that I will not again at present allude to it, only to remark that in small gardens, where it is desirable to include something of everything, flowers must necessarily be admitted and made the most of.

I now come to the want of variety, which is occasioned mainly by the occupation of so much space by commonplace subjects as Laurel, Holly, &c. Most pleasure grounds are repetitions with a vengeance, and I would advise the thinning-out of these shrubs considerably, leaving only the best specimens, and introducing in their stead more ornamental subjects, which would be more in accordance with the views before expressed and the advanced stage of gardening. Almost anything would be better than the tangled condition presented by the trees and shrubs forming a majority of shrubberies. It may gratify to see trees and shrubs struggling for mastery, but it does not constitute the beauty resulting from their subjection to culture, whereby we bring out the beauty of the

individual tree or shrub, and at the same time enhancing the general effect.—G. ABBEY.

### KENSINGTON GARDENS.

THIS beautiful place of public resort is 250 acres in extent, and is pre-eminently favoured by being the chosen resort of rank and fashion. Kensington Gardens are surrounded with wealth and luxury, and are the centre of a fashionable quarter of the metropolis. The mighty power of money is evidenced on all sides in the magnificent mansions which have risen during the last few years, where only a short time previously were fields and market gardens. The change has been from comparative insignificance into affluence and fame; but the Gardens seem to present nearly the same general features now that they did when surrounded by market gardens, and were then, as now, remarkable for the splendid old trees which are to be seen in all parts; and judging from the healthy young trees which may be seen growing, and the great ability displayed in the planting of them, there will be no lack of shade for generations to come, for here we have beautiful avenues, groves, and glades among young trees growing every year into beauty.

The fine lines of young trees that form the avenues running from the round pond to the east, north-east, and south-east were planted by the late Mr. Mann forty-six years ago. The old trees had then been decaying for some years, making gaps that young trees could not fill; and as there was space sufficient to admit a line of young trees being planted in front of the old this was done, and the result is that there are groves of half-grown and flourishing trees, the older and taller trees in the rear towering above them, and blending their foliage with them in a very pleasing manner. The ornamental effect of their association is greatly enhanced in the autumn, for the old trees change colour before the young trees, bringing out with marked distinctness the variety of foliage-tints and clear outline of forms. It is said that in a grove or an avenue the same object is seen from beginning to end. Granted, but here is a perpetual change, for here are groves of Limes and avenues of Elms; in fact they meet and cross each other in all directions, and there are also groves of Chestnuts, Hornbeams, Planes, and Beeches. These have a simple and grand effect without any sameness or even formality. In the spring time there is something very charming in these rows of trees; every line has its peculiar tint of green, which is soft, fresh, and delicate, and they are very enjoyable especially early in the morning. Nature's works are more beautiful at daybreak than at any other time, when the glittering dewdrops are still fresh upon the leaves, and the music of birds around you singing sweet songs of welcome to the opening day; and assuredly you may catch a wafting of flowery perfume, for the murky vapour emitted from surrounding chimneys cannot hinder the trees from growing, the birds from singing, nor the flowers from blooming.

There are many pleasant walks and promenades to be found in these Gardens. From the high road, Kensington, to the high road, Bayswater, is a gravel walk 60 feet in width, and on each side are stately old Elm trees in excellent health. The banks of the Serpentine in these gardens, popularly spoken of as the Long Water, have been much improved by the planting of ornamental trees, shrubs, beds of Rhododendrons, and flowers; also good gravel walks have been made leading to the fountains, which materially enhance the beauty of the place. The water forced into the air assumes a variety of beautiful forms, which, added to its clearness and its familiar sounds, is very refreshing on a hot summer's day. North-east from this point the Gardens are very picturesque. There is that pleasing variety of outline for which scenes in nature are eminently distinguished; there is also a natural disposition of trees and shrubs, with ornamental waters, serpentine walks, plantations, and avenues, so associated as to form an harmonious whole. At this part of the Gardens there are some massive old trees, one of the most picturesque is a Wych Elm. Its knotty trunk is about 6 feet in diameter. Its foliage, though massive and thick, never appears heavy to the eye, owing to the lightness of the spray and the loose free manner in which the leaves adhere to the branches. This part is also adorned by a most beautiful specimen of the Horse Chestnut; it is standing alone, and has expanded its branches over a large extent of ground, forming a charming summer shelter; there are also many fine Beeches. The Beech attains to a great magnitude when standing alone, and exhibits the appearance of a round-headed and spreading

tree, but when it is surrounded by other lofty trees it loses this characteristic. One here surrounded by Lime trees is 120 feet in height, and the trunk 6 feet from the ground is 12 feet in circumference. The Beech is one of the most ornamental of forest trees; its smooth bark, its dignity, its pendulous boughs, and its glossy foliage render it a chief ornament in any landscape. For public walks, drives, and avenues it ranks in the first class for picturesque beauty. An avenue of Beeches may be seen from the fountains, as shown in the engraving, running in a south-westerly direction. There is no fear of Kensington Gardens becoming an open plain if the planting of trees is carried out as it has been for the last forty-five years.

The Albert Memorial is a fine addition to the Gardens, and is at all times a source of admiration to visitors, and the general opinion of observers concerning this fine piece of work

and down to a much later period there were restrictions in force, giving the Gardens something of a private nature, but now they are free.—N. COLE.

### A TWO-STOURED PLANT HOUSE.

THERE can be no question about the present age being one in which improvements in almost every department are being sought for and adopted. Dwellings of all kinds are now-a-days constructed on principles which adapt them better to their requirements, and horticultural structures assume various forms. The disposition to make the most that can be made of a given space is in itself praiseworthy, and we now see crop succeed crop with but little intermission. In the construction of buildings adapted for fruit or plant-growing vast improvements in the construction and heating have taken place, and mechanical

Fig. 53.—KENSINGTON GARDENS.

is that the Prince was worthy of it, as he did so much for the arts and sciences during his lifetime. This portion of Kensington Gardens formerly belonged to Hyde Park, and a few years back was taken away on the principle of robbing Peter to pay Paul; and those who can remember this corner when belonging to Hyde Park, and will compare what it was then with what it is now, will best appreciate the alteration, for what was an untidy and desolate-looking piece of ground has been transformed into a charming pleasure ground.

The long flower walk is the most fashionable and at the same time the pleasantest promenade in the Gardens; it is 700 yards long, and possesses many charms. The botanist of high culture may be gratified and the public be interested, for here is a large assortment of choice trees and shrubs on each side of the walk correctly named, and the shrubberies are fringed with herbaceous, bulbous, subtropical, and bedding plants.

The Ivy cottage in the Gardens and its semicircular garden plot opposite attracts thousands of admiring spectators during the summer months, and for their comfort chairs are placed in shady spots under the forest trees by which the cottage is in part surrounded. The round pond near the palace was made in the reign of George II. by his consort Queen Caroline.

The Gardens were almost private in the reign of George II., the public being admitted on Saturdays only when the King and Court were absent, and then only in full-dress costume,

contrivances of various kinds have been brought into use. Neither have improved modes of cultivation been neglected; and when a more simple plan is devised than that previously adopted the knowledge thereby obtained is turned to account, and plants requiring shade as well as those delighting in the full sunlight have been each accommodated with suitable dwelling places.

A noteworthy example of this as well as of the use that may be made of a limited space was exemplified at one of those fashionable villas which are rising in the neighbourhood of large towns. In the case alluded to was attached to the residence a horticultural building of a kind I had not previously seen, being, in fact, a two-storeyed conservatory; not a gallery or raised pathway over a plant house, enabling the observer to look into the tops of the plants as in the large conservatories of Kew, Chatsworth, and other places, but one plant house over another, in the same manner that one dwelling room is over another. The lower one of the two here alluded to was devoted to Ferns, while the upper one was for flowering plants, being, in fact, a conservatory with creepers, &c. I could only obtain a passing glance of the two, yet I could see sufficient to prove that the Ferns were doing well, and there could be no reason why the flowering plants should not prosper equally well. The upper structure was entirely of glass, the lower one lighted all round with glass.

The plan may be adopted elsewhere, but to me it was new,

and I thought novel and well adapted for many situations where space is valuable.—J. ROBSON.

### NOTES AND GLEANINGS.

ALTHOUGH the FRUIT SHOW, which was announced to be held at South Kensington on November 8th, is officially postponed, there is reason to believe that the meeting of that date will be of more than ordinary interest. The competition for the prizes offered by Messrs. James Carter & Co. and Messrs. Sutton & Sons cannot fail to bring out some worthy products; and the excellent suggestion of Mr. Gilbert in the *Gardeners' Chronicle*, that gardeners should show their respect for the "old Society" by exhibiting fruit, &c., will possibly be acted upon by those who are able to do so. What may be done by voluntary effort and good will was well shown in the nurserymen's exhibition of last year, and Mr. Turner has again notified his intention of exhibiting a large collection of Chrysanthemums; and we hear that Mr. B. S. Williams also intends to contribute largely out of the abundance of his extensive and valuable storehouse.

—MR. DICKSON of Arkleton thus refers to two new Grapes—the DUKE of BUCCLEUCH and VENN'S BLACK MUSCAT:—"I grafted two of the former last year, and so far they have done well. I had five bunches on one and two on the other." Alluding to the keeping qualities of "the Duke" Mr. Dickson states that he has a bunch hanging now in a perfect state which was ripe in August. He has a good opinion of this Grape, which he describes as "a grand Grape when well grown." On Venn's Muscat he writes: "This also is a good Grape, and most decidedly I think it quite distinct from Muscat Hamburgh. I have it inarched on Muscat of Alexandria and also on its own roots."

—MR. A. BOYLE in a note on the TOMATO DISEASE observes that "W. C. Smith and 'SOUTH DEVON' have somewhat misconceived my meaning when I said 'My experience appeared to show that Tomatoes take the true Potato disease from neighbouring Potatoes whenever there is wet weather.' By this I did not mean that Tomatoes do not otherwise take that disease, only that they would more certainly do so (and probably to a worse extent) in the circumstances named. The instances I cited of Tomatoes in my neighbourhood at a distance from Potatoes escaping the disease were adduced to show this merely, and not that the plant in question is always free from that disease when away from the Potato."

—WE have had sent to us a profusion of ANTIRRHINUM FLOWERS, each different and all raised by Mr. Candwell, florist, Wantage. They are large, handsome, and of the best strain.

—MR. JOHN ATKINSON of Brigg writes to us as follows on LARGE MUSHROOMS:—"Having seen an account in your Journal of September 28th of some large Mushrooms which had been gathered in Ireland, I thought it might be interesting to your readers to know that a still larger specimen of *Agaricus arvensis* has been found in England. I picked on the 10th of this month in an old pasture at Winterton in the county of Lincoln a Mushroom, the two diameters of which measured 1 foot 1 inch and 11 inches respectively; the weight being 1 lb. 9 ozs. This Mushroom was most delicious when cooked."

—MR. A. J. TEMPLE, formerly steward and gardener to Mrs. Roe, Nutley, near Dublin, has been appointed gardener and general estate superintendent at Hartsholme Hall, Lincoln, as successor to Mr. Holah. Mr. Allis, who was formerly gardener at Hartsholme, is now manager of the old Warden Hall estate near Biggleswade, belonging to the same proprietor, J. Shuttleworth, Esq.

—IN the list of our imports from British India TEA is distinguished by the large increase shown in the returns for last year. The quantity rose from less than 18,000,000 lbs. in 1874 to upwards of 25,000,000 in 1875, and the value advanced to nearly £2,200,000, giving Tea a place among the articles for which we pay India more than £2,000,000 sterling in the year. The Indian Government report on the financial year 1874-75 states that the cultivation of Tea is rapidly spreading in Bengal, and the amount of the out-turn is now amply remunerative. The prices obtained in the market are such as show that the average quality is good, and, indeed, the industry is in an infinitely better and safer position than it was ten years ago. The native labourers are well treated by the European planters, and are generally contented. The best labourers come from Nepaul, and bear a good character for

industry and aptitude. In the Darjeeling district the increase of area under Tea cultivation in the year was 3193 acres, and the increase of out-turn was 971,201 lbs. The average yield of an acre was about 325 lbs.; in 1872 it was about 256 lbs. The Tea plant was introduced on the Neilgherry hills about forty years ago, and now covers nearly 2000 acres. The China variety, with which the oldest of these estates are planted, is the most hardy, but grows slowly and produces very little leaf; the Assam variety, on the other hand, grows rapidly and is a large producer of leaf, but it requires a sheltered situation on a rich fertile soil. The cross between the two is the most generally useful.

—REFERRING to STRAWBERRIES as a FIELD CROP, the *North British Agriculturist* states that a grower near Cupar-Angus netted £400 this season from three acres of Strawberries on thin land. The plants on which these grew were four years old. Another near Perth refused £2800 for the crop of twenty-eight acres of Strawberries, and the offerer was to have gathered the crop, which was a splendid one. Aberdeen and its surrounding districts have for years been famous for Strawberry production. This year, however, the crop has not been quite so good there as it sometimes is, neither in quantity or quality. Strawberries have, however, been a good crop in some parts of Perthshire and Forfarshire, and have paid the growers handsomely. The cost of planting an acre does not exceed £20, and the plants remain good for several years. On thin land in Kent many acres are devoted to Strawberry culture, and few other crops pay the growers so well.

### NOTES ON VILLA AND SUBURBAN GARDENING.

THE FLOWER GARDEN.—If not already done, all tender plants which are needed for store plants should be taken up and potted before frost comes and injures them. We annually take up a large number, and the work is done with much care, especially among variegated sorts. Some of the roots may be shortened and some of the foliage removed, and a few of the strongest shoots may be cut off, so as to make the plants compact and convenient to pack into close quarters. Sandy loam and leaf soil is suitable compost. We generally use boxes of a convenient size and depth, also in some cases pots, and the plants are put in thickly and kept in a cool, dry, airy place. A slight bottom heat for a time to induce the plants to make fresh roots is good, but is not always provided in an amateur's garden. Many plants can be preserved through the winter in frames if means are adopted to keep them secure from frost and damp. Verbenas can be so kept, but the plants must be dusted with sulphur occasionally to keep mildew away. A dry bottom for the pots is necessary, and an inch or two of ashes put down will be an advantage in placing the pots level. Both cuttings and plants should be freely exposed as often as possible with safety so as to have them well established. Water should be very sparingly given, and if possible on bright mornings, and then the lights can be left off till the foliage is dry.

Prepare a place for *Calceolaria* cuttings, which may be inserted now. It is a very easy matter to strike them. The shoots chosen should be those which have not flowered this summer, and which are now growing and healthy. They should be cut into lengths of about 2 inches, removing some of the lower leaves, so that the cuttings may be dibbed in the soil about an inch—just sufficient to make them firm. Light loam, leaf soil, and sand will be a suitable compost, but it must be sifted so as to press closely against the cuttings. The bed in which they are to be struck should be made level, and the cuttings put in rows about 2 inches apart, and afterwards watered sufficient to settle the soil about them. Many thousands can be put in in a day if needed. They must be protected from frost, and after being rooted exposed to air and sunshine; but before that they must not be allowed to flag from the effects of sun, or they go off. They are not subject to suffer from damp, but moisture rather favours their rooting. I sprinkle my cuttings every morning, and if they are put in properly not one in a hundred will fail to root. In the spring the points of each shoot must be taken out, which will cause them to produce side shoots. Attention must be given to the timely thinning-out of the plants, for if they are allowed to grow thickly together the shoots run up weakly, and the plants never recover their compactness. The plants which are taken out may be planted in another bed or potted, and all of them will be ready for planting out in spring before any other bedding plants.

Old plants of *Calceolarias*, if taken up and potted and placed in a cold frame, will pass through the winter safely, and in spring they will produce fine large bunches of yellow flowers which will prove very useful and ornamental. The plants will need manure water at flowering time.

Chrysanthemums are now coming on quickly, and if the buds are plentiful it will be well to thin out some of the smallest,

which improves the size of the flowers. The plants need plenty of water daily to preserve the leaves in a fresh green state.

Trees, shrubs, and evergreens may now be transplanted, and one general rule does for all. For every plant a hole should be dug out wide enough for the roots to be spread out freely, placing the soil carefully among them and treading it in well. Afterwards give a copious watering sufficient to penetrate all the soil, and fasten the trees to stakes to secure them against winds.—  
THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

We have now finished gathering Apples and Pears, and have them all arranged on the shelves in the fruit room. Some of the latest sorts would hang upon the trees until the middle of November or later; but it is not desirable to allow them to do so, even if there was no possibility of their being injured by frost. Fruit that is intended for use during the spring months (and some of it may be preserved up to midsummer) should first be placed in an airy room, and spread out as carefully as possible. Here it ought to lie for a few weeks, and by that time some will have decayed, and should be removed as soon as possible to prevent the decay spreading. The fruit should then be removed to a cool cellar where frost cannot gain access, or a cool fruit room where the sun does not shine on it would be equally well adapted for the purpose. Many persons may not have all the above conveniences. It is well to note that a room with windows facing south, and the walls only 9 inches thick, is very well for ripening fruit off when its season is near at hand; but such a room is about the worst place for late fruit, Apples especially in such a room shrivelling prematurely.

There are various methods of preserving Apples in a sound plump condition for late dessert purposes. I once saw some fine well-kept specimens exhibited by a clergyman at a provincial exhibition in Scotland in early summer or late spring. They were much admired, and were the objects of considerable attention at the time. They had been placed in fresh moss clean and slightly damped. The late Mr. Knight, who gave considerable attention to the keeping of fruit, considered the following mode the most successful. Earthen vessels, each containing about a gallon, were used. Each fruit was surrounded with paper, and the vessels were placed one over the other, the space between the top of one and the base of another being filled with a cement composed of two parts of the curd of skimmed milk and one of lime to perfectly exclude air. The vessels were placed in a dry cold situation where there was little change of temperature. He also found the merits of the Pears to be greatly increased by their being taken from the vessels and placing them in a warm room for about ten days before they were wanted for use. I have kept fruit well by placing each separately in paper and packing it in boxes, filling up the interstices with fine dry sand.

Many persons keep Gooseberries and Currants by placing nets or mats over them. It is necessary to remove the protectors on fine days, to remove all decaying leaves or mouldy berries. When the bushes have become dry, mat or net them up again. Birds, mice, and other depredators make strenuous efforts to get at the fruit. Trap the mice, and see that the birds do not find their way through the coverings.

No time should be lost in preparing ground for fruit trees. If the soil is not in good condition it ought to be trenched at least 2 feet deep if the nature of the ground will admit of it. When the trees were planted at Loxford Hall the ground was very poor and had never been trenched. Trenching was done in November, and the trees were planted at once, placing some good maiden loam round the roots of each tree. They made fine healthy growth the next season, and in October the borders were again trenched and the trees replanted. As the operation was proceeded with a barrowload of loam was placed around the roots of each tree. This was necessary, as the ground had been planted with fruit trees for nearly, if not more than, half a century. A very liberal supply of manure was also worked in with the soil, but not placed in contact with the roots, and the results have been very satisfactory.

Pruning of wall, espalier, and other trees may be proceeded with, and digging and trenching should be done at once. There is nothing like having all work forward when the weather permits.

### PINE HOUSES.

This is excellent weather for ripening fruit; very little artificial heat being required. The ventilators can be opened to a considerable extent by day, and may be closed early in the afternoon, leaving the top lights down about half an inch all night. Some little judgment is necessary as to the proper amount of water to be applied to the roots of the plants, as well as to what is allowed to evaporate in the house. If a Pine plant is in good condition and sufficiently moist at the roots when the fruit begins to change colour, probably no more water will be

required until the fruit is quite ripe. During the dull cold days of winter very little water is required to the roots of fruiting Pines.

If it has not already been done, all the plants should be arranged in their winter quarters. The fruiterers in different stages require a night temperature of 65° all through the winter months, and a bottom heat of from 85° to 90°. The best winter Pine, taking all points into consideration, is the Smooth-leaved Cayenne. It must yield the palm for flavour to the Black Jamaica, but this last-named variety is not to be depended upon to start into fruit just when it is wanted, and the fruit is very often not more than half the size of the Cayenne. Charlotte Rothschild sometimes throws a noble fruit, but often disfigured by having an overgrown crown. Those plants intended to start early next season are now at rest; very little water is applied to the roots, and the night temperature is 55°. By far the best variety for early forcing is the Queen, and it is the best sort to grow for market purposes. Good Queens weighing from 3 to 5 lbs. will generally fetch about 6s. a pound on the average.

Many persons keep the succession plants growing-on all through the winter months, but as a rule this is neither necessary nor desirable. Growth made at the "dead" of winter is of the palest unhealthy green. The plants will be at rest if the night temperature is kept at 55° and they do not receive much water at the roots. We admit air as freely as possible.

### GREENHOUSE AND CONSERVATORY.

Chrysanthemums have all been placed indoors. Most of the plants had been attacked by mildew, but this was destroyed by dusting the leaves with flowers of sulphur. There are many specifics warranted and patented to destroy this pest; probably most of them will answer their purpose, but nothing else is necessary except sulphur pure and simple. It may either be used by dusting or mixing the powder with soft-soapy water. The mixture may be applied with a syringe, or if the plants can be dipped in the solution so much the better. When there is green fly on the plants it must be destroyed by fumigating. Damp is very injurious to the large blooms intended for exhibition, the outer petals become mouldy, and decay soon spreads amongst them. The decaying petals must be promptly removed, and the house should be freely aired. Care must also be taken that no water is spilled when applying it to the plants. Specimen plants are being trained into shape either for exhibition or for decorative purposes. The Pompon varieties do not require to have the flowers supported by sticks, but the large-flowered section must have each bloom supported, and good culture is recognised when there is a sufficient groundwork of healthy green leaves to almost hide the stems and sticks, and to prevent one seeing into the centre of the plants. If specimens of the highest merit are intended they should be placed quite near the glass, have plenty of light and air, and not be crowded with other plants.

We have potted the Hyacinths and Tulips. Many of the roots were making signs of growth, either by pushing out from the crowns or by emitting roots from the base. It cannot but be injurious to the bulbs and to the future strength of the plants to allow much growth before potting or planting them.

Green fly made an appearance on stage Pelargoniums, tree or perpetual-flowering Carnations, and other plants in the greenhouse. Fumigation with tobacco smoke was resorted to at once. It is very desirable to destroy all the aphid tribe on its first appearance, or even if none are seen on the plants at this season fumigating two or three times at intervals of three days is desirable. We have been training hardwooded plants as opportunity offered.

### FLOWER GARDEN.

We have been clearing-off the summer bedding plants in order that the beds may be planted with Wallflowers and other plants for spring flowering. Beds of Pelargoniums grown for their foliage, and plants such as Iresine, &c., look better now than they have done at any time during the summer; but it is not safe to leave out any plants of this kind after this date. It is now time that all the spring-flowering plants were in their places, so that they may be established before the weather becomes colder.

Auriculas have been removed into a sunny position. They are liable to suffer from damp if the decaying leaves are not removed. In watering great care is necessary to prevent the leaves being wet. Carnations and Picotees have been potted and also placed in frames, the pots being plunged to the rims in cocoa-nut fibre refuse. Pinks planted out about a month ago are now well established and growing freely.

Roses are giving us some very fine flowers; they are very large and more highly coloured than usual.—J. DOUGLAS.

## TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Evergreens, Climbers, &c.*

D. McKenzie & Son, The Nurseries, Cromarty and Tain, N.B.—*List of Transplanted Forest and Fruit Trees, Shrubs, &c.*

Eugène Verdier, fils aîné, 37, Rue Clisson, Gare d'Ivry, Paris.  
—*Catalogue of Gladioli, Roses, Pæonies, &c.*

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LIVERPOOL (Chrysanthemums). November 2nd. Mr. R. Wilson Ker, 6, Basset Street, Church Street, Hon. Sec.  
JERSEY (St. Helier's) (Chrysanthemums). November 8th. Col. H. Howell, Hon. Sec.  
SOUTH BERMONDSEY (Chrysanthemums). November 13th and 14th. Mr. D. Jewiss, Roseale Arms, Rosebury Street, Bermondsey, Sec.  
NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.  
WIMBLEDON (Chrysanthemums). November 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Hon. Sec.  
BRIXTON HILL (Chrysanthemums). November 17th and 18th. Mr. G. Goldfinch, Sec.  
LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapmazz Street, Loughborough, Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

NAMES AND ADDRESSES OF GARDENERS (C. C.).—They are given in the "Horticultural Directory," which may be had by post from our office for 2s. 3d.

NAMING FRUITS AND PLANTS (R. B.).—When we omit any it is because we do not recognise them.

STOVE FOR GREENHOUSE.—"N. C." wishes to be informed of one that does not cause a disagreeable smell in the house, and will continue burning throughout the night.

MADRESFIELD COURT GRAPES (Reason).—No box has been received.

TRANSPLANTING A LARGE RHODODENDRON (An Old Subscriber).—Rhododendrons possess such an abundance of roots that no special preparation is required for the transplantation of the largest specimens; just take care to secure as large a ball of soil about the roots as is practicable, and you may remove it at once or at any favourable time onwards to the spring.

VIRGINIAN CREEPER FOR COVERING A HOUSE (Idem).—For a very lofty building the large-leaved strong-growing variety *Ampelopsis hederacea* is best, for it will attain a height of 50 feet and cover an area of 1000 square feet of wall surface in five years if planted in good soil—a rich loam—and carefully trained. For lesser heights, say of 20 or 30 feet, we altogether prefer the more elegant and compact growth of *Ampelopsis Veitchii*. The foliage of this kind, however, changes to a deep bronzy purple, and is less brilliant in colour than *A. hederacea*.

HYBRID PERPETUAL GARDEN ROSES (Mrs. Holmes).—Reds: Alfred Colomb, Dupuy Jamain, Madame Victor Verdier, Sénateur Vaisse, Dr. Andry, Duchesse de Caylus, President Thiers, Marie Baumann, Etienne Levet, and Comtesse d'Oxford. Dark and Crimson: Charles Lefebvre, Duke of Wellington, Duke of Edinburgh, Fisher Holmes, Louis Van Houtte, Maréchal Vaillant, Pierre Notting, Prince Camille de Rohan, Xavier Olibo, and François Louvat. Rose: John Hopper, Thorin, Victor Verdier, Madame G. Schwartz, Madame Therese Levet, Annie Laxton, François Michelon, Marquise de Castellane, La Ville de Lyon, and La Duchesse de Morny. Pink: Berthe Baron, Elie Morel, Monsieur Noman, Gloire de Vitry, Emille Hausburg, Abel Grand, Comtesse de Chabrillant, Marguerite de St. Amand, Lyonnaise, and Madame Clerf. Light: Baronne de Rothschild, La France, Madame Noman, Boule de Neige, Madame Lacharme, Mdlle. Bonnaire, Mdlle. Eugénie Verdier, Sophie Coquerel, Bessie Johnson, and Gloire de Dijon (Tea-scented).

COMPOST FOR PLANTS (E. J. T.).—*Stephanotis floribunda*—equal parts of fibrous loam and sandy fibrous peat, with a fourth part of leaf soil and a sixth part of silver sand. *Euphorbia jasquiniflora*—light fibrous loam three parts, with a part each of leaf soil and sandy peat, and a sixth part of silver sand. *Hoya bella*—light fibrous loam and sandy turfy loam in equal parts, with a fourth of pounded bricks or broken pots and a sixth part of pieces of charcoal and silver sand. *Clerodendron*—fibrous loam three parts, two parts sandy peat, and a part each of old cow dung or leaf soil, some pieces of charcoal, and silver sand.

RED-FLOWERING STOVE CLIMBER (Idem).—*Passiflora princeps* has very persistent foliage and long cyrnes of flowers. It has never been out of flower with us for the last five years. *Ipomoea Horsfallii*, deep rose, is very fine about this time, and *Combretum grandiflorum* has scarlet flowers, and flowers in summer, usually during May and June. We prefer the *Passiflora*.

CLIMBERS FOR NORTH WALL (Idem).—Besides the Ivies, which are first-rate, you may plant *Ampelopsis hederacea*, *A. Veitchii*, and *Clematis vitalba*, with *Jasminum nudiflorum*, which are all deciduous.

CARNATION AND PINKS FOR WINTER-FLOWERING (N. C.).—We presume the plants are well established in pots, and in a forward state. All they require is a light airy house, and a temperature of 50° to 55° by day, and 50° at night. The Pinks to be introduced to such a house from an ordinary greenhouse early in November, and a few plants subsequently at intervals of about three weeks to keep up a succession of flowers; then be kept near the glass, have air freely in mild weather, and be duly supplied with water.

EVERGREEN AND DECIDUOUS SHRUBS FOR A SMALL GARDEN (Idem).—Evergreen:—*Arbuta japonica maculata*, *Buxus elegantissima*, Holly (gold

and silver-variegated), *Viburnum tinus hirtum* (Black-leaved Laurustinus), *Berberis Darwinii*, *Yucca recurva*, *Rhododendron* in variety, *Andromeda floribunda*, and *Kalmia latifolia*. Those, except the *Yucca*, may all be cut into form as they become too large, and in that way be kept compact. Conifers, which are best for the lawn, are—*Abies excelsa* and *A. clausbrasiliana*, *Biota (Thuja) orientalis aurea*, *B. orientalis elegantissima*, *Cupressus Lawsoniana compacta*, *C. Lawsoniana erecta viridis*, *Juniperus chinensis*, its golden variety (*J. chinensis aurea*) being very beautiful, *Retinospora pisifera*, *Taxus adpressa stricta*, *T. baccata elegantissima*, *Thujopsis borealis compacta*, and if room for a tall specimen, *Pinus cembra*. Deciduous shrubs are—*Cotoneaster Simmoussii*, *Cydonia japonica* and var. *candidissima*, *Deutzia crenata flore-pleno*, *D. gracilis*, *Hydrangea paniculata grandiflora*, *\*Syringa persica incisa*, *S. persica alba*, *\*S. rubra insignis*, *\*Pæonia Montan var.*, *\*Philadelphus nausus*, *\*Ribes sanguineum flore-pleno*, *Spiraea arifolia*, *\*S. ulmifolia*, *Rhus Cotinus*, *\*Viburnum dentatum*, *\*Weigela amabilis* and its white variety, *\*W. rosea*, *W. rosea Madame Conturier*, and *\*Azalea pontica var.* If too many deciduous shrubs are named select those distinguished by an asterisk.

ESPALEIR ROWS (J. E.).—They should be about 6 feet apart, being 5 feet high.

ASPHALTE FOR VINE BORDER (Vitis).—A good authority tells us that he knew the bottom of a Vine border rendered impervious with asphalt, without any injury to the Vines planted and grown on it for several years subsequently.

ADIANTUM FARLEYENSE (E. B. G.).—It is a native of Barbadoes and requires a stove temperature.

BENZOLINE FOR DESTROYING SCALE (A. B. P.).—As it answered so well on the *Maréchal Niel* Rose, we think it might be used for the same purpose on *Camellias* and other plants. Try it on one specimen, and then you will have the best tutor—experience.

TUBEROUS BEGONIAS (Old Subscriber).—Your "tubers" recently received are, we presume, in a dormant state. Place them in very sandy soil and keep through the winter in a greenhouse where the temperature is not below 40°. The pots should not be placed on a dry airy stage, or the tubers would become too much shrivelled. A rather damp floor would be preferable on which to place the pots, or they might be syringed occasionally to prevent the soil becoming dust-dry. In the spring when the tubers show signs of growth put them in a compost of loam, leaf soil, and sand, and place them in a gentle heat, such as is afforded by a Cucumber frame, subsequently removing them to the greenhouse as the plants attain growth.

HOUSE FOR ROSES (J. E.).—Your idea is a good one. You could not have anything better than a span-roofed house, with about 2 feet of brickwork above ground, and 3 feet of side lights, the width inside between the walls being 9 feet, having a border on both sides of the wall upon which the pots could be placed; but we should prefer to have the Roses planted out, and in that case we should have a foot more of side lights and a foot less of brickwork. At least a square yard of space should be allotted to each plant, so that your house will need to be as many yards in length as you have plants on the side, but less space will suffice for a time. The borders should be 3 feet wide, with a pathway up the centre of the same width, over which you can have trained at about a foot from the glass the vigorous-growing Roses as *Maréchal Niel*. It will be necessary to provide plenty of ventilation, having the side lights to open the whole length of the house. Tea-scented Roses as you propose would be the most eligible, but you will need to have a gentle warmth in severe weather—a 2-inch hot-water pipe along the sides of the house would be sufficient.

GRAFTING TRICOLOR PELARGONIUMS UPON ZONALS (E. D. L.).—It is performed in the ordinary manner, both by whip or tongue-grafting, cleft or wedge-grafting, and not unfrequently by saddle-grafting. We think saddle-grafting most preferable, leaving a leaf upon the shoot operated on so as to attract the sap. The *modus operandi* cannot well be described without illustrations, which are given in the "Science and Practice of Gardening." The plants after grafting require to be kept close, moist, and warm. Inarching is a certain method of operation.

STOPPING WALLFLOWERS AND ASTERS (Linda).—If the Wallflowers are stopped now they will not flower well in spring. These and many other plants are made leggy by allowing them to grow too thickly. They should be pricked-off when large enough to handle, and with plenty of room in an open situation they will be dwarf and well-furnished. Asters are not stopped, but they are grown-on slowly, and not drawn-up weakly by too close and warm an atmosphere in their early stages.

KEEPING GRAPES IN LATE VINERY (C. H. J.).—If you wish "Doings of the Week" you will find the information you require. The other question has been answered in a previous number.

FRUITING YOUNG VINES (D. W.).—We advise you to cut the canes of the permanent Vines back to 3 feet from the base of the rafters. Each cane, if strong and well ripened, will bear two or three bunches next season without any injury to the Vines.

MILDEW ON VINES (Irish Subscriber).—If Vine borders are in good condition, and the vinery is sufficiently ventilated, this parasite will not attack the Vines. Placing sulphur on the paths would do no good, nor would it on the hot-water pipes unless the fumes were thrown off by the pipes being heated to a considerable extent. You had better dust the affected parts with flowers of sulphur as soon as the mildew appears. At the same time keep up a night temperature of 65°, with as much ventilation as possible.

SOWING SEEDS OF LILIES (A. B.).—The seeds remain long in the ground before they germinate. You might sow in March in a gentle bottom heat, or now, and place the pot in a greenhouse.

GRAPES BECOMING MOULDY (J. J.).—No doubt the damp weather is the cause of this, aggravated in your case by the want of ventilation in the front of the house. Cut-out the mouldy berries as soon as they are perceived, to prevent decay spreading to the others.

DESTROYING INSECTS (R. S.).—Thrips may be destroyed by fumigating with tobacco smoke on two or three consecutive nights, repeating the doses in three weeks, when other insects will be hatched. The Vines, stages, and woodwork of the house should also be thoroughly washed (when the Vines are pruned), with strong soapy water, dissolving 3 or 4 ozs. of soft soap in each gallon of water, and applying it when hot, removing any plants out of the way of the hot solution. The walls should also be limewashed, mixing in the wash some flowers of sulphur. This thorough cleansing will also greatly check the red spider, which may be further prevented from doing injury by frequent syringings and the maintenance of a moist atmosphere

in the house. For the present fumigate and afterwards syringe, and then when the leaves fall from the Vines give the thorough cleansing as advised.

**HYACINTHS AFTER FLOWERING** (*Idem*).—As soon as the flowers fade remove the spikes and place the plants in a frame and attend to them by watering, so as to perfect healthy foliage, and when this shows signs of ripening withhold water. When the foliage has died down the bulbs may be removed from the soil and preserved in a cool place until September, when they may be planted in the garden or potted. They will not produce spikes equal to those from imported bulbs, yet will be attractive and useful. The great point to aim at is to keep the foliage fresh as long as possible after the Hyacinths have ceased flowering.

**NAMES OF FRUITS** (*J. Woodliffe*).—2, Nelson's Glory; 4, Minchall Crab; the others not recognised. (*J. Beck*).—1, Alfriston; 2, Bedfordshire Founcling; 3, Claygate Pearmain; 4, London Pippin. *Pears*: 1, Marie Louise; 2, Bergamotte Cadette; 3, Triomphe de Jodoigne.

**NAMES OF PLANTS** (*J. S. W.*).—We cannot recognise plants from leaves only. (—).—*Anemone vitifolia* and *Anemone alba* are not the same. *Anemone Ponorine* Jobert is the same as *Anemone japonica alba*. It is one of the finest of all hardy autumn-flowering herbaceous plants. (*W. D. H.*).—The glaucous-leaved plant is *Sedum Sieboldii*, a hardy evergreen, native of Japan. No one could name a Rose from such a specimen.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### THE BLOT ON THE CRYSTAL PALACE PRIZE LIST.

WE have purposely waited until the Crystal Palace entries have been closed a week before referring to the subject of what appears to us a repeated mistake. By thus having waited we can in no way be said to damage the class in question by anything we are going to say, still we feel we cannot let the subject pass without one word of remonstrance.

We allude to the class for untrimmed birds at the coming Crystal Palace Show. After the tumult and warfare connected with the subject in bygone months, we did hope that on this occasion, in mere justice to the main body of exhibitors, the title of the class would have been differently worded. This year, however, as last year, the title runs, "Any other variety (not Game) not trimmed or plucked in any way." Last year, however, we found on the top of the class in the catalogue the words, "Vulture-hocked birds are eligible in this class." We considered this amusing, and could not help wondering for whose edification the words were printed. Not for the Judge, as he, we conclude, would not have the catalogue while adjudicating; not for the exhibitors, as they wanted to know that interesting piece of information before they entered, and not afterwards. So it must have been for the critical public; but surely they would have had sense enough to see that a vulture-hocked bird was eligible as much as any other bird shown honestly with any peculiar failing of its own. The class filled well last year, and made £10 10s. in entry fees, which, considering the first prize was a gift, placed a handsome balance to the good. If this was the reason of the repetition, very well, it is but natural that the promoters should look to their returns, and we can well understand their doing so in most cases; but here we do think it a somewhat different case. Let anyone look at it in every possible way, and we fail to see how they can come to a different conclusion to our own—namely, if an exhibitor shows in that class and in others, he affirms that his birds in the latter section are not honestly shown, while those in the untrimmed class are. We can understand it in no other way, and we hope that our chief exhibitors have this year avoided the class which we call the blot on the otherwise brilliant escutcheon of the Crystal Palace Show.

We have been told that the Committee kept to this class under its old name in mere bravado, because the class succeeded last year in spite of opposition; but this we will not believe, and we think even now the managing powers must have some underlying reason which is not so far apparent to us. Now, all know the value of hocked birds in Brahmas and Cochins for breeding purposes; had the class consequently been for "vulture-hocked Asiatics" we would have welcomed it warmly, though these are frequently ugly birds, which, invaluable as they are for some purposes, are best kept at home. Still, the class would have been more definite, and would have been well patronised we feel sure. We would not on any account wish to be misunderstood. We have had no conversation on the subject with anyone, and simply write in the interests, as we consider them, of all poultry exhibitors. It would delight us very much to hear that even now the class was to be confined to vulture-hocked birds, and perhaps to Spanish, and with a very little correspondence with those who have already entered this might still be done. We know how the subject was talked over last year, and how visitors criticised the "perfectly natural" birds, and wondered how so many scores and scores of other specimens were allowed to be exhibited in any way different to the state nature had given them. We think it is a pity that this should be so; and for this reason, and this only, do we take the subject up to-day, to touch upon it afterwards no more. Perhaps, however, we feel this nomenclature the more because there

is another grievance which is not remedied this year. We allude to the system of wanting all pens to come in single baskets; but we will not say much of this to-day, as all our readers know our feelings in this matter; and since such a mass of well-conducted shows now permit the use of the double baskets, which tend to so greatly increase their entries, proof of no other sort is needed to point out the wishes and feelings of the great body of exhibitors. The enormous entries at Oxford this week show us that chickens abound, and many of them of good quality; so in spite of the one foul quartering on this national coat of poultry arms, we once more hope to see the catalogue with four thousand entries and over.—W.

### OUR DUTY TO OUR FOUR-FOOTED AND FEATHERED NEIGHBOURS.—No. 2.

"He that doth the Ravens feed,  
Yea, providentially caters for the Sparrow."  
*Shakspeare's "As You Like It."*

BEFORE leaving the subject of the fens and birds that were there, let me notice how a name of a great king who reigned in this country, and over Denmark and Norway as well, is preserved by a little bird. I allude to one of the Sandpipers, the "Tringa Canutus." This bird is called commonly the Knot. It was a favourite dish of Canute, King of England; he who reproved his courtiers on the seashore. The bird was first called the Knute, then the Knout, and in process of time the Knot. Canute was a man of great ability and vast power, but all has passed away; his name preserved by an anecdote, and kept up by a little bird! A just process of reasoning may trace the bird to the king, and prove that there was such a king and so named. He little thought when feasting on his favourite dish of ash-coloured Sandpipers, that this insignificant long-legged slender bird before him would preserve his name. Such is fame, and so preserved. London arabs whisper to each other at the sight of a policeman, "Here's a bobby coming." O, shade of the great Sir Robert Peel! that nickname makes your name known to this generation. Who scarcely, but for it, would remember you? for the statesman's name, like the actor's, is in all men's mouths when alive, but is little remembered when dead. Another, and yet another actor comes on either stage, and "he too plays his part" and vanishes.

I have now come thus far in my reasoning. Birds and beasts at first abundant or rather super-abundant; man killed them for food, and to prevent their eating up his food. Presently it came to pass that man's weapons became weapons of precision, and were terribly fatal to the life of beast and bird. No longer the blundering off-failing bow and arrow, but the deadly gun came into use against bird and beast life. Then, in addition there is that love of destruction—of taking life, strongly developed in some men. Such cannot see a number of Rooks sailing in the air but long for a gun to kill some of them. These destructive men were when boys great robbers of nests; they could not see a bird on a bough but they must stoop and pick up a stone to kill it with. The prettiest Chaffinch whistling its May-day song was not the whit more secure than a chirping Sparrow. "Kill, kill," is the cry of such. A little later the boy becomes the hedge-popper; not a Finch, not a Linnet is safe. One moment it is a thing of beauty—bright-plumaged and happy as its little full heart can contain, all its fulness, love, and life, and enjoyment; the next a little mangled heap of misery—wing-broken, blood-soiled, legs smashed. Oh! for very pity rush up and wring its neck.

The French sarcasm has some point, I fear, even yet. "Happy Englishman!—it's a fine day, go out and kill something." Does a rare or curious bird appear it is sure to be killed, be it Bustard, or white Swallow, or cream-coloured Blackbird. There are plenty of imitators of Charles IX. of France, who cry out "kill, kill," and join in the killing. Nor are the other sex wholly free from blame in this matter of the threatened extermination of small birds. In the last century there was a fashion for feather work, and the bright blue feathers of the Jay's wing were specially prized. The poor birds would have been unknown to us now-a-days save by pictures, only the fashion changed. Fashion! oh, Fashion! Sidney Smith called the three per cents. the greatest fools on earth, from, I suppose, their changeableness at any breath of rumour. He might have instanced the more fickle goddess called Fashion, now dressing her votaries in balloon-like petticoats, and then a few years after, as now, in such skimpy garments that going up a flight of stairs is an impossibility. But these fashions only regard the inconvenience of the wearers and punish their devotees. But there is another fashion, that of ladies wearing stuffed specimens of small birds, even English birds, in their hats—birds such as Goldfinches, Chaffinches, and the like; yea, I have even beheld a Robin there. If this fashion continue it will lead to something like an extermination of some of our prettiest and most innocent songsters. Its effect upon Goldfinches is such that a bird-dealer now gives 2s. 6d. to any boy who brings him one, whereas 6d. used to be the regular price.

Simple carelessness of taking life is in the boy, and some men, who are said to love a gun! You like shooting, young man, do you, and your means do not allow you to be a sportsman? Go, then, and join a volunteer corps and shoot for a prize, but do not harm God's harmless creatures. There is a sacredness as well as a beauty in life, which must not be invaded save for a good cause. You must not kill "all for the pleasure of making a little noise." This low sport should be frowned down upon by all thoughtful people. *Punch*, whose instincts are always healthy, gave, I remember, some years since, a fancy picture of the chairman or first-prizeman of a Sparrow club, and 'twas the very likeness of a snob indeed. Sometimes cruelty is simply the result of ignorance, as in the Sussex gamekeeper, who always shot the Cuckoos because he thought they turned into Hawks in the winter. This good man had clearly no idea of the migration of birds, but had a queer notion of claws to think that the innocently-shaped foot of the Cuckoo could be changed into the talons of the Hawk. Another instance of the cruelty of ignorance came to my knowledge. A gardener used to walk about armed with a club, with which to pound and smash frogs and toads, wholly ignorant that a toad in a cucumber frame is treasured by many gardeners as a true friend. I think nothing more repulsive to kindly human feelings can be imagined than a man going about smashing into pulp harmless and even useful creatures. Victor Hugo has a fine passage descriptive of cruelty to a poor toad that happened to be in a public path:—

"A man who chanced to pass descried the brute,  
And shudd'ring, crush'd its head beneath his foot.  
Then came four schoolboys, cheerful as the sky,  
Giddy with hope and sport, and spirits high;  
Loud, free, and happy; how get through the day,  
Save by tormenting weak things in their way?  
The toad was crawling slowly, seeking shade,  
The children spied it out and shouting ran,  
'Here, let us kill the nasty thing,' they said.  
And since he's ugly hurt him all we can.'  
'The vicious thing, he foams!' the children roar,  
At every blow the froth starts more and more.  
Head crushed, eye hanging, one leg torn away,  
Through grass and briar he forced his wretched way.  
The children, rosy-cheeked and flaxen-haired,  
Said 'twas the finest sport they ever shared,  
Talked all at once; at last devised to throw  
A good large stone to give the final blow."

Then comes a poor wretched ass with his heavy cartload. The children watch to see the wheel crush the poor toad, but the poor suffering ass, despite the driver's shouts and blows,

"Stiffened his bleeding muscles 'gainst the load,  
And turned the wheel aside and spared the toad."

The children notice this—

"Then one small hand the stone it held let fall,  
And of those children, one—he tells the story—  
Heard sounding from the great sky's arch of glory,  
A voice that said, 'Be merciful to all!'"

Would that such words could ring in the ear of every child when about to injure or needlessly take the life of any bird or beast.—WILTSHIRE RECTOR.

## EXHIBITORS OF WHITE FOWLS

SHOULD bear in mind the effect of sunlight upon white plumage. Such birds as are designed for the autumn and winter exhibitions should be cooped or penned where they are shielded from the strong glare of the mid-day sun, and where they cannot wallow in any clayey soil. A clean dust bath of sand and ashes is best for health and looks.

The penning should begin with the growth of the feathers after moulting. The yellowish tinge given by a strong light will be found almost impossible to remove after once appearing; and there is no time when the plumage is more susceptible to change of colour than in the early stages of growth, while the feather is yet soft.

The difficulty of cleansing soiled plumage is well known; and with a very little ordinary care and precaution the necessity of this measure may be spared.—(*Pet-Stock Bulletin*.)

## AGRICULTURAL HALL POULTRY SHOW.

*Spanish* commenced the poultry classes (twenty-five entries). The mild weather has undoubtedly conducted in a great measure to the forward condition of the birds. First a pen of fine-grown chickens, but a little coarse in quality. The cock's comb upon close inspection we fancied had been very skilfully sliced at the back, apparently to lighten the weight and keep it perpendicular. This should have deprived him at least of any post of honour. Second (362b) a pen of coarse old birds. We could not understand this award, and thought the Judges must have intended the award for the next pen (363b), a fair pair of chickens, belonging to the same owner. Pen 362 a fine cockerel, and honestly shown, and we should have liked to have seen him in the first position. Quite half a dozen pens that were passed over by the

Judges we thought deserved cards. Pen 342 (Jones) a beautiful pullet, one of the best in the class, with a fair cockerel; pen 341 (Hewes) a cockerel of good quality, but very young; pen 347 and pen 349 good old birds, out of condition, but better than the second-prize pen. We noticed two or three pens in this class with cut combs. In common justice it should be understood, if this is to be allowed, then all can exhibit on an equality; but it is most annoying and unfair for an exhibitor to find that he has cast a good-faced bird away through a falling comb, and then find another exhibitor has succeeded in obtaining a prize by lightening the weight of the comb with the scissors.

*Cochins*.—Buffs a good class. First a grand cock, hen fine, but slightly marked on the hackles; second good in colour; third also a fine pair. Pen 422 (Burnell), hen very good, cockerel beautiful in colour, but not well matched. 428 (Procter) a pretty pen, but small. Partridge.—Mrs. Tindal was easily first, hen well pencilled; second, Lady Gwydyr. White.—First (Boissier) an exquisite pen. Pen 449, second rather leggy and wanting in shape; we should have placed Mrs. Tindal's pen before it. Pen 448 (Fowler) a fine hen.

*Brahmas*.—Darks.—First (Mrs. Tindal) a good-coloured cockerel, pullet well pencilled but small. Pen 474 (Lingwood) a grand cock; we considered him the best bird in the Show; his mate was not his equal, but she was a good hen. 456 (Newham & Manby) a well-marked pullet with many good points. Pen 471 (Ans dell) a fine old cock, not quite over his moult. Lights disappointed us very much. Pen 475 (Lingwood) first, cock badly twisted in the hackle; he reminded us very much of a Pouter Pigeon; in all other points he was the best in the class. Second (Saville), hen a little creamy, otherwise they would have been first. 480 (Petter) a good pair of chickens, but too young for exhibition. Mr. Breeze and Mr. Chawner, jun., exhibited some fair pens.

*Games*.—Reds, first (Martin) a pen of most stylish Brown Reds in beautiful condition; they were deservedly awarded the champion cup. Second (Hassell) a good-colour cockerel; tail a little too perpendicular. The Duckwing and Pile classes were quite up to the standard.

*Any other variety*.—The ordinary classes being very restricted, this class contained an unusual combination. All varieties of Bantams were competing with Polands, Malays, and various breeds of large birds too numerous to mention. The winners deserved their prizes, but the selection was a great question of fancy. Several other pens might have been chosen without giving grounds of complaint.

[We had not received the remainder of our reporter's notes at the time of going to press.—Eds.]

POULTRY.—SPANISH.—1, J. Walker. 2, G. J. Chilcott. 3, J. Pitt. DORKINGS.—Coloured.—1, Viscount Tarnour. 2, J. Coppel. 3, R. Chessman. *White*.—1, G. Burnell. *Any other variety*.—1, T. C. Burnell. 2, O. E. Cresswell. 3, Hon. Mrs. Colville. *Cochins*.—Buff.—1, R. P. Percival. 2, A. J. Swindell. 3, Lady Gwydyr. *White*.—H. Tomlinson. Partridge.—1, Mrs. A. Tindal. 2, Lady Gwydyr. 3, E. Tadman. *White*.—1, R. A. Boissier. 2, S. R. Harris. 3, R. Chase. BRAHMAS.—Dark.—1, Mrs. A. Tindal. 2, H. Lingwood. 3, Rev. J. D. Peake. *White*.—Newham & Manby. Light.—1, Horace Lingwood. 2, Capt. W. Savile. 3, T. A. Dean. GAME.—Reds.—1, H. E. Martin. 2, T. Hassall. 3, T. Mason. Duckwings.—1, P. Dyson. 2, J. H. Staveley. 3, H. E. Martin. *Any other variety*.—1, H. Mason. 2, and 3, T. Burgess. *Bantams*.—Silver-pencilled.—1, H. Beldon. 2 and 3, J. Webster. *Silver-spangled*.—1, Duke of Sutherland. 2, H. Beldon. 3, J. Fielding. *Gold-pencilled*.—1, W. K. Tickner. 2, Duke of Sutherland. 3, T. Lees. *White*.—W. Anderson. *Gold-spangled*.—1, J. Long. 2, A. Hyde. 3 and *White*.—H. Beldon. CREVE-CEURS.—1, J. K. Fowler. 2, S. Vickery. 3, R. Park. GEES.—1, J. Stott. 2, J. K. Fowler. 3, J. Walker. *White*.—Dr. E. Snell, Hon. Mrs. Colville, H. Beldon, R. Gladstone.

## THE BRISTOL SHOW SCHEDULE.

This year the Bristol schedule has come earlier than usual, and we find its dates arranged for the old Birmingham week. We heartily hope the time gained will bring Mr. Cambridge increased support. The old classes are much as usual, but we find some new classes in addition—namely, two for Black Cochins, two for White-crested Black Poles, one for Silkies, &c.; and above all we are especially glad to see the variety Bantam classes better arranged. The entry fees remain the same, and in these days of increasing time rather than diminishing them this is something to be thankful for. The poultry Judges are Messrs. Hewitt, Teebay, and J. H. Smith; the latter gentleman has been especially engaged for the Game and the Game Bantams. Mr. Dixon was invited to help, but could not come. Mr. Cambridge writes to us to say he is quite prepared to obtain the services of a fourth poultry Judge if the entries necessitate the same.

In Pigeons the point cups are no more. We can imagine great rejoicing in the county and field pastures. The Judges are Mr. P. H. Jones and Mr. Charlton. In other respects the Pigeon classification is good, and the prizes liberal. There is a champion cup of £10 value for the best pen in the Show. The

entries close on the 7th of November, and we hope all will enter well.—W.

### A RETROSPECT.

TO-NIGHT I look back over half a century and find myself a romping "wee callan" (a little boy), jumping amongst my father's hives of bees, and courageously turning them up to see how their combs were being filled and when they would be ready for swarming. I was at an early age drawn into the mysteries of bee-keeping. Two generations of intelligent and successful bee-masters in his district have well-nigh passed away since my juvenile days. I owe much to the past and those who were before me, for I had a pretty wide and comprehensive experience amongst bees before I was fifteen years of age. In making this statement there is no boasting; the circumstances and surroundings of my early days were favourable. Though it is more than forty years since I left the home of my youth, I have had something to do more or less with bees during these years. I have seen bee-keeping in Middlesex, Hertfordshire, Oxfordshire, Yorkshire, Lancashire, and Cheshire, often in its most ancient phase, and sometimes in its most modern one. For more than twenty years after I came to England I could see no signs of advancement and success. The books that fell from the press had comparatively little weight or influence; but now I am pleased to know that things have taken a turn, that bee-keeping is moving, in many places advancing; and I earnestly hope and confidently expect that it will speedily become an uplifting power in many homes of the rural and working community. After this preamble I will review the season of 1876 from an apian point of view.

In Cheshire the season was very unfavourable until the middle of June. It could hardly be more unfavourable both for honey-gathering and breeding. Many hives all over the county and elsewhere died from their want of bees. From all I could hear I opine that more than half of the hives in England perished before brood was hatched in them. The autumn of 1875 did not encourage the bees to hatch brood late, hence the span of their life was reached this spring before young bees were reared to take their places. Some may have died from want of food, for the weather was so unfavourable in March, April, and May that bees had not a chance in this neighbourhood of gathering honey. For about the first time in my life I was discouraged and thoroughly tired of feeding my bees. I gave it up for a time, very much to their injury and my loss. About the middle of June the weather became more favourable for honey-gathering, and the bees began to prosper. They collected honey rapidly, filled their hives with bees, and readily swarmed, though a month later than their usual time of swarming. Stock hives generally were heavy at the time of swarming, and the earliest swarms did pretty well for a while. The last half of July and first half of August were unfavourable for bees in this part of the country. The bees that were taken to the moors had a few fine days from about the 12th to the 20th of August, but then the heather was not sufficiently in blossom and did not yield much honey. The best swarms in this neighbourhood rose to 70 and 80 lbs. each, one or two to 90 lbs., but the great bulk of swarms never approached that weight, and almost all second swarms and turn-outs were failures. The honey weather did not last a month altogether in this locality. Those who managed their bees on the non-swarming system have been most successful here, probably elsewhere as well, for in late and short seasons swarms are placed at a disadvantage, and have an uphill battle to fight. This year the weather became unpropitious before the hives were filled with combs.

From the East Riding of Yorkshire and other parts of England I hear that good harvests of honey have been obtained. In the south of England some excellent supers of honeycomb were filled. The products exhibited at the Bee-keepers' Association fête, held this year at the Alexandra Palace, were highly satisfactory. At the Dundee Show some exhibitors appeared in good form. Their productions would tend to give a healthy impulse to bee-keeping in that part of Scotland. The "RENFREWSHIRE BEE-KEEPER" has favoured the readers of this Journal with a statement of his astonishing success with a Stewarton hive this year. Mr. J. E. Briscoe of Albrighton has been equally successful with a Stewarton hive and Italian bees, as may be seen in last week's Journal. My correspondent at Carlisle, Mr. G. Henshilwood, writes that "the spring here was cold and backward for bees. Indeed, they lost all the fruit blossoms in spring, and that made them late in swarming; but towards the end of June and during the month of July we had some very warm days now and again, when the bees gathered honey very fast. An old stock that stood in my own garden was never above 17 lbs. weight till the end of June, when I took a swarm from it. Two weeks after this it weighed 56 lbs. Some of the first swarms at the end of the clover season weighed from 50 to 90 lbs. each. One at Crossford, belonging to Mr. Cadzow, rose to 105 lbs., but I was told that two swarms united in swarming and were hived together. On the moors the weather broke before the heather was well in blossom. The average gain per hive on the moors

would be from 20 to 30 lbs. Many hives came home from the moors above 100 lbs. each. One at Crossford was 150 lbs. You see the season has not been a bad one upon the whole; indeed, I may say that the bees had a better touch on the clover this year than they ever had before since I came to Carlisle, twenty years ago. Our hives were all too heavy for keeping, so we took the honey from them, united the swarms in pairs, and fed them into stocks."

From the neighbourhood of New Pitsligo, Aberdeenshire, my friend Mr. George Campbell writes "that the spring was most unfavourable until the 22nd of June, when the summer weather set in and remained favourable for our favourites till the 20th of August, when they were entirely shut up for the season. My first swarm was obtained on the 29th of June, which, being sold previously, was sent off by rail the same night. My next swarm came off on the 2nd of July, and weighed 7½ lbs. (bees alone), from the stock that yielded a swarm of 9 lbs. on the 9th of June last year. The swarm this year rose to 103 lbs. on the 21st of August, having filled a hive 20 inches by 16 inches. A cast from the same hive eleven days later rose to 57 lbs. This is my best result from one hive this year. I had three stocks over 100 lbs. each, the heaviest being 114 lbs.; but they were late in swarming. As young princesses were given to them twenty-four hours after swarming they gave no casts. Five of my stocks I did not intend to swarm were working in supers, but, as if by mutual consent, they all swarmed on the 17th of July, and three of the swarms alighted as one and were hived in a 20-inch-by-16 skep. The bees alone weighed 16½ lbs. and filled the hive. A 6-inch wooden eke was given to this hive, and was filled with combs in fourteen days. I then put on a half-filled super, which they filled in three days, putting 3 lbs. a-day into it. I put another half-filled super on the top of the first, as it was not all sealed though quite full, but instead of finishing it the bees took down all the honey in it. The five stocks all gave casts, but as the season came abruptly to an end they did no good. Their combs will answer for starts to swarms next year. Throughout this district first swarms range from 36 to 80 lbs. only, owing to the lateness of swarming. Second swarms are generally worthless. I have heard of only one swarm beside my own that reached 100 lbs., so I conclude this season has not been equal to 1874." My friend Mr. Shearer is gathering up the results of the Huntley district of Aberdeenshire.—A. PETTIGREW.

### BAR VERSUS STRAW HIVES.

I SHOULD be sorry if the supers exhibited by me at the Alexandra Palace, containing 131½ lbs. of honey, the product of one hive, were looked upon by the advocates of straw skeps as a proof of "what can be done with them when compared with bar-frame hives;" or that the splendid supers from Mr. Cowan's bar-frame hive should be compared with mine as the products of "wood versus straw." Let me at once say that in my opinion—an opinion by no means hastily formed—the advantages gained by the use of bar-frame hives are so great that straw skeps cannot be compared with them. I am as rapidly as possible transferring all my bees to the former hives; and those bar-frame hives which I had in use this summer gave me in proportion a greater weight of honey with half the trouble and annoyance than did closed straw hives. From swarms of the current year, placed in hives with alternate sheets of empty comb and guides of wax, in which five large combs had therefore to be built before supers had a chance of being entered, in three instances I took off two of Lee's supers and a box of sections, the total weight from each hive being over 60 lbs. Into a bar-frame hive which I made with double glass walls I put a heavy swarm May 30th. Each of the ten frames had a plain guide sheet of wax an inch deep. In thirty days from the date of swarming this hive was filled from end to end with combs, all full of brood or sealed and unsealed honey. On the 1st of July I placed a box of sections with guides over this stock, and July 15th a bell-glass by its side. At the close of the honey season I took off the bell-glass and sections well filled and sealed, total weight 42 lbs., leaving the stock hive with 50 lbs. With Abbott's "Little Wonder" I extracted from it close upon 20 lbs. of the purest liquid honey, and returned the combs, excepting some corner pieces which broke away. This hive and all my other frame hives are at this date filled with young bees, the surest promise of a good harvest next spring, weather permitting.

My large Pettigrew skeps furnished me with powerful swarms, with which my bar-frame hives which I made during last winter were stocked. Two or three of these large straw hives reached the weight of from 70 to 90 lbs. But what an undertaking it was to get out the best honey! Most of it was stored at the top of the hives. Perhaps about 15 lbs. of good comb could be cut from the sides of each hive, but to get at the bulk of the honey the whole of the brood comb had to be cut out. What a waste would have been here if I had not had empty frames at hand into which I patched the dark pieces, and thus from two or three skeps took a quantity of run honey and stocked a bar-frame hive, into which the bees were thrown. Now, had

all those beautiful combs been in frames, the extractor would have relieved the hive of its superfluous weight, and the combs and bees would have been left otherwise undisturbed as promising stocks for the work of next spring. There is no doubt whatever that great weights of honey may be obtained from large skeps, and those who have changed their small for large skeps have made a great stride in the right direction; but those who have taken another step and changed their large skeps for bar-frame hives are much nearer the goal of success.—P. H. PHILLIPS.

### CAPS OF CELLS.

I AM glad to see from the courteous letter from Mr. Pettigrew on page 337 that he no longer thinks bees secrete wax specially to cap brood cells, and that therefore the only point on which we differ is—whether they draw out the edges of the cells or cut down old comb for the purpose of forming caps. As I have never noticed the wholesale tearing down of cells, which, according to the last of these theories, would be necessary during extensive breeding, I incline to the first opinion as expressed in my last letter, especially after an experiment with worker comb which I made this year.

I fitted into a frame a sheet of artificial worker-comb foundation of a very peculiar yellow colour, and found that when the bees had carried out the foundation in all its length there was just sufficient wax to form worker cells with clearly defined rims. After the queen had duly furnished the cells with eggs, and the time was come for the grubs to be covered in, I discovered that the caps were all formed of the same coloured wax as the foundation I had given to the bees. Now, as I know there was no other wax in the hive of that colour (they did not cut any of the sheet down), I do not see how they could have done otherwise than draw out the edges of the cells.

The only solution of the matter that I can suggest is that when a grub has evacuated its cell some of the young bees clean the latter out (of course leaving the well-known skin in), and then strengthen the edge of the cell. The rim is often a trifle lighter in colour, and this strengthening would be more apparent but that so little material is used, that being well incorporated with the old wax it cannot but somewhat agree in colour with it. May it not also be dirtied by the thousands of feet passing constantly over it? This is only a suggestion, and I know it has several weak points; but can Mr. Pettigrew bring forward a more plausible theory, giving some proofs of its correctness?

I have not experimented with drone comb, for there is so little in my hives, as I cut most of it out, but should think that a theory applying to one sort would be applicable to the other also. The sides of a queen cell, when the latter is ready to be capped, contain so much material that I fancy bees could easily find sufficient to form several caps.—J. P. J.

### THIS YEAR'S HONEY SEASON.

Now that the season of 1876 is over I think it will afford pleasure to the readers of our Journal if bee-keepers will send to you their experience of this season, so that we who are admirers of our little pets may compare notes as to the best kind of hive to give the largest amount of honey, also the best means of securing the beautiful glasses which are from time to time being exhibited at our shows. I may also say that bee-keeping is becoming a mania, if I may use the expression, for in this part of the county (South Lancashire) I am continually being asked to go over to see this gentleman's and that lady's garden to see if the place is favourable for establishing an apiary, and I can only account for it by the fact that several local agricultural societies in Lancashire and Cheshire give prizes for bees and honey, as do some of the horticultural societies; but they want to see glass hives as well as straw, for they say they are more attractive and give the young apiarians a taste for bee-keeping.

I sent my glass hives to the Winter Gardens at Southport last month for three weeks; they took nearly £20, and the charge was 1*d.* each to see them. They were placed in the conservatory. Since then I have had applications from other societies to let them have hives next year.

I began this spring with eight hives, having lost five during the winter (gross neglect), and thought I should have lost them all, the spring being so late and cold; but at last fine weather came, and the bees took advantage of it and lost no time in storing the sweets. My first swarm came out June 20th, which I put into a 16-inch Pettigrew hive. After that I had several swarms up to July 10th. My last went away; I saw it go, but could not get the bees down.

We have had a good white clover season here, and some good glasses of honey, but not large, owing to the large hives not being generally used. I took ten hives to the heather. The first ten days the weather was splendid, but the heather was not fully in flower, it being late, but the bees did well until the weather broke and the wet set in. If it had been fine for three weeks longer it would have been the best season I remember,

for there was a great profusion of flowers. One of Pettigrew's hives (a swarm) came home 80 lbs., besides giving a super 20 lbs. I had several small supers as well as the one referred to above, and upon the whole they have done well, each hive being able to spare 10 lbs. of honey. My stocks consist of one ten-bar Woodbury straw hive, two nine-bar Woodbury, one of Nutt's hives which filled me one of its side boxes, one of Huber's book or leaf hives, the rest straw, with the exception of my glass hives. I have all the bees snug for the winter with plenty of food, and hope next year to increase my stocks to about thirty.

I must admit that if we want large stores of honey and early swarms we must use large hives, for the prolific properties of the queen are not generally known amongst bee-keepers.—SOUTH LANCASHIRE BEE-KEEPER.

### OUR LETTER BOX.

FLOOR OF FOWL HOUSE (*Lu Shaw*).—Do not pave it, but have gravel covered with 3 inches in depth of sand, from which you can rake the dung as needful. The soft flooring is preservative of the fowls' feet.

HENS EATING EGGS (*K. B.*).—Your only remedy is to take the egg as soon as laid, and to leave porcelain nest eggs.

FOWLS AT EGHAM (*E. T.*).—The nearest show to you will be at Dorking, December 7th.

CRUDE AND PERFECT HONEY.—Mr. Pettigrew writes to us that he has answered "B. & W.'s" questions on the above subject repeatedly, and declines replying to his letter in last week's Journal.

### REMARKS.

18th.—Warm, rather misty day, sunny at intervals, but damp evening.

19th.—Very foggy morning, but warm beautiful day.

20th.—Damp dull day; cooler towards evening.

21st.—Much cooler, a very fine bright day.

22nd.—Dull cold morning; slight rain at times during the day and a wet night.

23rd.—Cold dull day throughout.

24th.—Dull all day, but without rain.

Although the temperature has fallen nearly 11° during the last fortnight, it still remains slightly above the average.—G. J. SYMONS.

### COVENT GARDEN MARKET.—OCTOBER 25.

A SHORT supply and slack business has been the characteristic of our market during the past week, scarcely any alteration taking place in prices. Pears and late Apples are in good demand. Kent Cobs are readily cleared at an advance.

From observations taken near London during forty-three years, the average day temperature of the week is 53.8°; and its night temperature 36.4°.

## ABOUT FIGS.

DID you ever see a Fig blossom?" asked a gentleman well learned in theological, archæological, and most other logical matters. "Oh, yes," I replied, "thousands." As he was evidently interested in the subject and failed to find the Fig blossom himself, I supplied him with specimens and such scanty information as I was in possession of. He said that he had looked in vain in Miller's "Gardeners' Dictionary"

and various other works for particulars and explanations on the subject. I hinted that it might not be understood in Miller's time. "It was understood long before Miller's time," said he, "for the subject is mentioned in the Bible, and some opponents of the sacred book say that the prophet was wrong, as the Fig does not blossom at all; but," continued he, "it seems the prophet was right."

I have never gone very deeply into the subject, although it is intensely interesting; but to those of your readers who would like to explore for themselves and discover the hidden beauties of the Fig, I will give a few hints which may serve to put them on the right track. I do not know the number of blossoms an average-sized Fig tree bears to within a few thousands, but if anyone will take the trouble to count the number of seeds a ripe Fig contains he will arrive at a tolerably correct idea of the quantity of blossoms necessary to produce a perfect fruit, and the multiplication table will furnish the rest.

The fruits which will ripen on outdoor Fig trees in this country next year are already visible in the axil between the leaf and the stem of this season's growth, and those which do not grow larger than a Radish seed this autumn will, if the wood is sufficiently ripe, in all probability produce perfect fruits next August or September. Those which are larger than a Radish seed will not survive the winter unless they enjoy a sufficiently high temperature to keep them growing—probably an average of 65°; and the same may be said of those formed on wood which is not thoroughly ripened, in which case the wood will be killed as well as the embryo fruit; but fruit of the size of a Radish seed situated on wood which is well ripened is at least as hardy as the fruit buds on an Apple tree.

The only difficulty about outdoor Fig-culture is to have the wood ripe; this difficulty overcome all the rest is of the simplest nature possible, and I hope to see this fruit more extensively grown.

My situation is not an enviable one for fruit-culture, the soil being very heavy, with a cold clay subsoil; nevertheless, for several years now I have been able to rely on a crop of Figs, although I cannot always rely on one of Apples and Pears.

There are many situations where Figs grow naturally without any special culture; the most likely places I believe are those on chalk or gravel; but where the subsoil is heavy and the atmosphere damp special culture is necessary. The special culture which answers here is

annual root-pruning and summer thinning of shoots. At the end of September a trench is dug out about a yard from the wall, the roots are all shortened-back with a knife, and the trench is refilled with soil as poor and open as is possible to obtain. This prevents the roots, and ultimately the shoots, growing too grossly and partially aerates the soil which contains the principal roots.

The pruning of the branches merely consists of cutting those clean out which are not required, leaving the rest at full length. This is principally done as soon as the fruit is all, or nearly all, gathered, when the trees have finished their season's growth, but still retain their leaves. Should the growth, however, become too crowded it may be partially thinned at any time during summer, but never in winter or spring, as the wounds do not heal so quickly when the plants are destitute of foliage. But I had forgotten about the blossom.

I have said the embryo fruit is already formed for next year; the embryo blossom may be formed too for aught I know, but at any rate it cannot be discerned with the naked eye. Next spring, probably about the end of May, when the fruit is about the size of a small Bean cut one of the small fruit lengthwise through the centre, and the blossoms yet unexpanded may be seen very clearly by hundreds, each one mounted on a separate peduncle of considerable length. Well, if these are the blossoms how is fertilisation to take place where not a breath of air can reach? Examine the end of the fruit farthest from the stalk and a hollow will be seen, but at present it is securely covered by small imbricated leaf-like organs, which protect the tender parts till such time as they become perfectly formed, when the door is opened and air is freely admitted to the centre of the fruit. This, I believe, is for the purpose of fertilisation, which takes place when the fruit is grown, perhaps, to a third of its size. The young organs are then extremely tender, and if, from the weather being unfavourable or the organs themselves being imperfect, fertilisation does not take place, the fruit grows to a certain size, when it, as well as the perfect fruits, cease to swell perceptibly for a time (this, in the case of the perfect fruits, is when they are forming the seeds), and then, instead of starting afresh, turns yellow and falls off.

The structure of the Fig at the time the blossom is coming to perfection is exceedingly beautiful, even when viewed through a common magnifying glass. A microscope would probably reveal beauties which I do not dream of.

The best proved sort for general outdoor culture is Brown Turkey; but I believe White Marseilles will do very well.—WILLIAM TAYLOR.

## CULTURE OF THE TULIP.

WE seldom read anything now in the gardening papers on the Tulip, but depend upon it this neglect is only for a season; the time is not far distant when the Tulip will be held in higher estimation than it is now. It is not many years ago when the late Mr. Groom of Walworth

catalogued three roots at one hundred guineas each, and many at ten and fifty guineas each. It is not to be expected that such prices will be given for single roots of Tulips again, nor is it desirable either in the interest of the trade or private growers that it should be so. A point that ought not to be overlooked is the fact that Tulips flower at a time when the flower garden is in a transition state, the spring bedding is over or nearly so, and the beds are being again dug and planted for the season. While this sort of work is going on the proprietor of a bed of Tulips can be enjoying the rich and varied colouring of the flowers, and there is such a wealth of variety in the white and yellow grounds, with rose, cherry, violet, purple, chocolate brown, and nearly black flame or feather, as cannot be found in any other flowers. Further, there is very little trouble with them; the beds can be made up and planted at a time when work is not pressing, and they require but little attention afterwards. Fashion has had much to do with the decline of the Tulip. First of all was the rage for the geometrically arranged flower gardens. Lawns were cut and tortured into all manner of fantastic shapes to form beds of various patterns and elaborate designs. Princely and ducal mansions have their magnificent flower gardens, and the owner of a small grass plot 10 feet square seeks to imitate them by having beds of *Palargoniums*, *Verbenas*, edgings of *Feverfew*, and *Chickweeds*, lines of *Beet*, and curiously inlaid beds of *Houseleeks*, *Sedums*, and what not. The spring bedding is now also a further strain on the energies of the sorely-tried gardener. In my boyish days every garden had its bed of show Pansies; but there are no Pansies, no Heartsease now. They are all *Violas*, and you must not admire the beauty of a single flower, you must look at the mass. The first question is, What sort of bed does it make? It must be a mass of yellow, indigo, black, or white; it must be a decided colour. That is the point. White and yellow-ground Heartseases will not do. Now, far be it from me to say a single word to discourage any style of gardening; it is all beautiful in its place, but it is a great pity that the rage for gaudy colours and large masses of flowers should drive such noble flowers as the Tulip out of cultivation.

Another reason that many persons do not grow Tulips is that horticultural societies do not encourage them. Now, all the great metropolitan horticultural societies have exhibitions just at the time when the Tulip is in its glory—that is, from the middle to the end of May, but none of them think it worth while to devote a class in the schedule to Tulips. This is not quite as it should be. Societies such as the Royal Horticultural and Royal Botanic should not offer prizes for flowers merely because they are popular, but more because of their intrinsic merit. Offering prizes for flowers does not make them any better, but it certainly increases the interest one takes in them. Note, for instance, the *Carnation* and *Picotee*. What a fine bank of flowers was shown at South Kensington this year! and I know at least three more growers in the neighbourhood of London who intend entering on their culture this year; they would not have thought of it had there not been prizes at the exhibitions. The Metropolitan Floral Society had a noble work to perform, but owing to some cause or other its members do not pull well together, and nothing has been done during the past year. There is a worthy band of true-hearted florists in the north, and they are willing to fraternise with their brethren in the south. When visiting amongst them only last August I found that all the principal *Auricula*-growers were willing to hold the National *Auricula* Exhibition in London next year. That is giving us the right hand of fellowship with a will, and it is for the southern growers to make all the arrangements and give them a most hearty welcome. It is incorrect to say that a date cannot be arranged to suit the northern and southern growers, for I find by referring to the Journal reports that the "National" for two years in succession was held on the last Tuesday in April, and the Metropolitan Floral Society held theirs both seasons on the following Wednesday. But this is a subject which must be entered into more fully on another occasion.

Yet it must not be supposed that the Tulip has gone out of cultivation altogether. There are many growers and there is also a National Society for its encouragement, and an exhibition is held every year in the north. Mr. C. Turner of Slough still grows a large collection for the purpose of trade, and his beds when in full flower are a splendid sight. Let us hope that a bed of Tulips may be soon seen in many gardens, even if the bedding-out should be curtailed to make room for it. It ought also to be known that when the Tulip bulbs are

dug up there is time for a bed of *Asters*, *Stocks*, or even bedding plants on the same ground.

As it is now time to prepare the beds and to plant-out the Tulip bulbs a few remarks may be useful to some readers of this Journal. I was taught at school that the Tulip "asketh a rich soil and the careful hand of the gardener." A rich soil is provided by trenching the ground to the depth of at least 2 feet and working-in plenty of rich manure. But to grow the Tulip well the bulbs ought not to come in contact with ordinary garden soil nor with the manure. Some sandy maiden loam should be placed around the bulbs, and they must be planted according to method.

The Tulip is divided into three classes, each of which is subdivided into two—namely, *Bizarres*, *Byblomens*, and *Rose*. "When the stripes of colour descend from the top edges of the petals two-thirds of the way down the middle towards the bottom" the flowers are *flamed*. "When the colouring is finely pencilled round the margin of the petals" they are *feathered*: the ground colour must be either pure white or yellow. In planting the bed the colours and heights must be judiciously arranged. There ought to be seven rows in a bed, and planted 9 inches apart in the following manner, the centre row being the tallest:—

1	2	3	4	5	6	7	8	9	10
Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose
Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.
Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.
Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose
Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.
Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.
Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose	Byb.	Biz.	Rose

The bulbs when planted should be about 3 inches below the surface, and it is sometimes desirable to place a little river sand around them. To preserve the Tulip bloom for as long a period as possible, a canvas awning must be erected over the beds to preserve the flowers from frosts and dashing rains. The varieties of the Tulip are very numerous, and but little has been done during the last few years in the way of introducing new sorts. Nearly all the varieties can be obtained at a cheap rate. The following are superior sorts:—

*Bizarres*: Caliph (Gibbons), Dr. Horner (Groom), Duke of Devonshire (Dickson), George Hayward (Lawrence), Glory of Abingdon (Pitman), Henry Groom (Groom), Everard (Bowler), King (Willison), Mr. F. Perkins (Groom), Dr. Hardy (Storer), Marquis of Bristol (Groom), Lord Raglan (Groom), Pactolus (Headly), Polyphemus (Lawrence), J. R. Scrivener (Lawrence), Sir J. Paxton (Willison), Owen Glendower (Sanders), Vivid (Sanders), Uncle Tom (Willison), Sphynx (Sanders).

*Byblomens*: Adonis (Headly), Blomart, or Mrs. Siddon's Claude (Strong), Clara (Storer), Chancellor (Battersby), Duchess of Cambridge (Groom), Duchess of Sutherland (Walker), Gem of Gems (Willison), John Kemble (Goldham), Lord Denman (Abbott), Maid of Orleans (Gibbon), Nora Creina (Lyde), Queen (Rutley), Queen of the North (Hepworth), Rachel Rush (Rutley), Victoria Regina (Groom), Violet (Alexander).

*Roses*: Aglaia (Lawrence), Arlette (Dixon), Baron Girsdorff Camuse de Craix, Duchess of Sutherland (Gibbons), Fanny Ellsler (Goldham), Gem (Goldham), Heroine, Kate Connor, and Lady Stanley (Gibbon), Maid of Falsie (Dixon), Mary Headly (Headly), Mountain Sylph (Headly), Magnificent (Hayward), Naomi (Headly), Rose Camuse, Rose Celestial (Barlow), Sarah Headly (Headly), Triumph Royal, and Vicar of Radford.

Some of the leading exhibition flowers shown at Manchester are—*Bizarres*: George Hayward, Masterpieces, Ajax, Demos-thenes, and Sir J. Paxton. *Byblomens*: Adonis, Violet Aimable, Talisman, Mr. Pickerell, Duchess of Sutherland, and Lord Denison. Amongst *Roses* the best are Industry, Mabel, Mrs. Lea, Aglaia, Triumph Royal, La Van Deeken, Mrs. Lomax, Lady Sefton, and Lady Catherine Gordon.—J. DOUGLAS.

## EARLY APPLES.

In writing this short note I do not propose to offer any opinion of the sorts which have been recently named in your columns, but to mention an early Apple which only requires to be known to be appreciated. It is "Early Joe," an Apple which, according to Dr. Hogg, is of American origin. I procured a bush tree of it on the Paradise stock for trial some years ago from Messrs. Rivers of Sawbridgeworth, and it has fruited abundantly with me every year. The fruit is very handsome, a true dessert Apple in size, form, and quality. It does not keep long, and like most summer Apples it is best eaten off the tree. I observe that in the "Fruit Manual" it

is described as "considerably resembling Devonshire Quarrenden in shape, size, and colour." As grown here the two have no resemblance to each other excepting probably in size, Devonshire Quarrenden being rather a shabby unpromising-looking Apple, while Early Joe is quite the reverse. It is hardy, and ripens perfectly on bushes here, and I should say the climate must be a very late one where Early Joe requires a wall.—D. D. A., *Forfarshire*.

## THE ROSE ELECTION—THE BATTLE OF THE STOCKS.

In suggesting this addition to the Rose election I had no idea that we should be able to settle the knotty question of the best stock for Roses, for as Mr. H. Merryweather remarked in his reply, "That would be as difficult as to settle a knotty point between half a dozen different religionists." Mr. Merryweather further remarks that the question of stocks is in a great degree a question of locality, and that certain soils require certain stocks for success. Our stocks, something like old Sam Weller's, "fluctooate" according to the ideas of the different growers, and are moulded in some fashion by their soil. Certain opinions seemed already tolerably fixed—that the Briar did not succeed well in poor light soil, whilst the Manetti gave better results in such situations. On the other hand, Tea, Noisette, and Bourbon Roses appeared to like the Briar better than the Manetti, whilst most of the Hybrid Perpetuals would prefer the Manetti—the summer Roses in my opinion declaring that it was "six of one and half a dozen of the other." On all hands it seemed agreed that the Manetti was not suitable for standards. Perhaps to all these propositions there are exceptions, even to the last.

In days gone by I have given in my adhesion to the Manetti as the most serviceable stock for general purposes. I must confess I am still its champion. Some few years back there was, I think, no question that the Manetti would have gained the vote, but the introduction of the seedling Briar and the marvellously successful results that Roses grown on this stock have shown in Mr. G. Prince's hands, has made the advocates of the Briar still more enthusiastic, whilst there are growers, not a few, who contend that even the seedling Briar is eclipsed by selected Briar cuttings.

No one who has looked at the seedling Briar plants can deny that there is a vigour about them peculiarly their own; and the blooms that have come from the Oxford growers have shown in the exhibition tent a corresponding amount of stamina. It may not perhaps be easy to decide who first attempted the seedling Briar as a stock. Very many years ago old Tom Cole of the Wellow Rosery near Bath, a place which the railway has I fear demolished, remarked to me, "If you want good stocks that will not throw-up suckers, sow the Rose seeds and bud below the radicles." He evidently had tried the plan. Mr. Tapner in his reply on this subject says, "Thirty-six years ago I raised seedling Briars, and found the Roses did well on them." One wonders if the blooms were anything like those of Mr. Prince's that the practice apparently went out.

The replies received on the question of stocks resolve themselves into several classes. Amongst these a large number give generally the answers that I have perhaps imperfectly stated above as acknowledged data. For instance, the Rev. Alan Cheales, Messrs. Burrell, Mayo, M. L. Davis, Jessop, Wooten, Tapner, and B. R. Cant consider the Manetti best for Hybrid Perpetuals, and the Briar for Teas and Noisettes; some amongst these also noting the difference in soils as suitable to one or other of these stocks. Then the Rev. H. Dombain, with Messrs. Smallbones, H. Davis, Berrington, and W. Curtis consider both these stocks very good, Mr. Smallbones leaning towards the Briar and Messrs. Dombain and Berrington towards Manetti, Mr. Curtis adding that he prefers the prepared Briar cuttings to the seedling Briar. Another division, including Captains Christy and Rochfort, Messrs. Mawley, Atkinson, Scott, John Turth, G. Prince, and Corp, vote more or less decidedly for the Briar in some shape, the majority naming the seedling Briar; Mr. Scott preferring the prepared cutting even to this, and Mr. Atkinson remarks that it depends somewhat on the situation. On the other hand, whilst admitting the preference of Teas for the Briar, the Manetti is supported as a general stock by the Revs. C. P. Peach and Camm, Messrs. Robson, Chater, Walters, Ewing, H. May, Davison, and the returning officer; Mr. Ewing remarking that the Manetti

has more merits than any other stock, whilst Mr. Peach adds, "Under no circumstances the standard Briar; the more I see of them the less I like them, and I hope the day is not far distant when standard Rose trees will be things of the past. Every dog has its day, and the Dog Rose as a standard has had its day."

In this verdict of Mr. Peach's I most heartily coincide. I determined years ago never to plant another standard Briar; relenting, I tried them again, and again I arrived at the same conclusion. I see them in other gardens where the Rose is not so much an object of consideration, and there I see these dead standards make a convenient pole for the *Convolvulus*. Much as I admire the latter, what a fall was there! What can be more horrible to a Rose enthusiast than a pole more or less, and generally more than less, covered with lichen, with a head that diminishes yearly in size, but in its own simplicity attempts to make ample amends for this by growing out thoroughly at the bottom. Fired with the great results obtained by Mr. Prince, and thanks to his kindness in sending me some seedling Briars, I thought to myself, Here is an end to my old favourite the Manetti; but though not averse to the seedling Briar stock, if I must vote I must again revert to my old favourite, believing that for general purposes it is the most serviceable and manageable stock. I grant all the splendour of the seedling Briar roots, which are beautiful, and account for the vigour of the plants as compared with the mopsticks that so frequently have nothing worthy the name of roots; but I contend that budding the seedling Briar is a far more difficult and less successful affair than performing the same operation on the Manetti. The seedling Briar root-stem is often anything but straight—it is as gnarled as the giant Oak of the forest, though only a seedling, and the result is, in my clumsy manipulation, deaths many! a pitiful array of plants that the following season are still only seedling Briars. Again, owing doubtless to the same cause, I have not found that absence of suckers which I expected. There is an irrepressibility about the Briar that will not be put down—that makes a root on the surface of the soil form a bud on the slightest provocation. The splendid head that the vigorous seedling makes renders the art of budding a great difficulty, and in my hands a doubtful experiment. Nor am I alone. Last year I had an expert budder to put in some forty or fifty buds; his success has not equalled my own. Now, with Manetti of my own manufacture I have no trouble—the operation is comparatively easy, and it is rarely unsuccessful, whilst the results of blooms are so little different, that, being essentially lazy, I throw up my hat for the Manetti.

I have still to note that Mr. Harrison prefers the Napoleon stock, then the selected Briar cutting, having scanty faith in the seedling Briar; whilst Mr. George Paul gives us a word of advice which is useful, that the best results are obtained by working each separate Rose on that stock, whatever it may be, that gives us the best results—there is in fact no universal stock.—JOSEPH HINTON, *Warrminster*.

P.S.—Mr. Jowitt's address, which was not attached to his list of Roses, is The Old Weir, near Hereford.—J. H.

## MY PRACTICE WITH GRAPES DURING THIS SEASON.

In the autumn of last year I gave the outside Vine border a good mulching of half-decayed cow manure, and allowed it to remain until about the month of April of this year, when I removed the most rough and slightly forked-in the remainder. Last winter, after pruning the Vines and washing the houses, I took off a little of the surface soil from the inside border and gave the border a top-dressing 4 inches deep of the following compost:—To one barrowful of fibry loam well chopped up I added half a stone of half-inch bones, half a stone of wood ashes, an 8-inch potful of soot, and a sprinkling of flowers of sulphur. I believe very much in a change of food for the Vine. Soot is a healthy ingredient for vegetation and a good preventive of mildew, and wood or stick ashes prevent the soil from becoming sour, and are, I think, a good colouring agent—at least they contain potash, which is one of the constituents of the Vine, and I should say that in a soil void of potash Vines will not thrive.

When the berries were about half swelled I mulched the inside borders with cow manure, which no doubt helped the Vines greatly during the very hot weather. In former years I syringed the Vines until the colouring period. This year I

withheld syringing as soon as the bunches showed signs of coming into flower, and I must confess that a decided improvement resulted in the bloom and finish of the Grapes.

I have now the means of heating the water and liquids that I feed with, which is a great advantage; and it may be well to explain that I procured an old engine boiler holding about four hundred gallons of water, and erected it over the furnace at the back of the vineries, considerably above the level, so as to have a good pressure. As soon as the liquid is of the desired heat, which I vary at different stages of the Vine's growth, I then screw on the hose, keep the fire going gently, so as to have the water at about the same heat, as I have a supply pipe running cold water in as fast as the warmed water runs out. By this mode of procedure one man can with ease give the borders a good soaking in half a day, and to greater advantage than by the old system of carrying it in water-pots; or, in other words, one man will do the work of three, which is no slight consideration, besides the water being much better for the growth of the Vines than are cold applications. Watering the inside borders with warm water also saves firing for several days, and the heat from the soil is more natural than that given off by hot-water pipes; also by this process guano and other ingredients are more thoroughly dissolved, and prepared as it were for the food of the Vines.

I am fully convinced that the majority of Vine borders are made up with too rich soil. I do not think that they should be all of the same compound—that is, I would prefer having them richer on the top than at the bottom, so as to keep the roots near the surface, hence my reasons for giving a little fresh compost every year. By having a border that is not too rich stimulants can be applied in a liquid state more freely, and that at a time when the Vines require assistance, and no doubt the food of the Vine is the most directly available when in a fluid state, hence a healthy root-action should be maintained, which may be done by studying the condition and requirements of the Vines.

I have during the past season used various liquids with very satisfactory results, such as manure water taken from the farm-yard where there are horses, pigs, and cows; guano water, soot water, and nitrate of soda. With the latter I am very careful, as it is a very powerful stimulant towards accelerating the growth of Vines.—JAMES DICKSON, *Arkleton*.

### HARDY PLANTS FOR CARPET BEDDING.

I AM glad to see that carpet bedding is taking a new turn, and that hardy plants are largely employed, and I should not be sorry to see it entirely limited to this class of plants; at all events a few beds might be devoted to them in every garden where carpet bedding is adopted.

In a general way the London parks and other public gardens present us with some of the best examples of flower gardening, but they are mostly of the class of showy plants of certain popular kinds; new, and especially hardy, plants being rarely met with. The latter are more likely to be forthcoming in country gardens where attention has been paid to alpine and hardy herbaceous plants, and it is surprising what good results can be obtained by the use of them alone.

In a very fine garden I visited a year or two ago in Dorsetshire there was an Italian garden glowing in all the colours of the rainbow, a series of large beds being well filled with the most fashionable and popular plants of the day; but a little way from them was a large circular bed arranged in a pleasing design with alpine and other low-growing plants, all hardy and thriving in the greatest luxuriance, and I was told it was more admired than the others with their glittering display. In the bed alluded to were many species of Saxifrage, Sedum, Sempervivum, and other low-growing plants displaying various forms of growth, and a very good contrast was made with the various shades of green and white, from the dense emerald green of *Saxifraga cespitosa* and *S. hirta* to the soft grey of some of the Sedums and Sempervivums and the white of *Cerastium tomentosum*, as well as all the neutral colours and pleasing forms of the various silver-gray Saxifrages, &c.

Since writing the above I see in a recent article attention is called to two hardy plants that are said to be adapted for carpet bedding, one of them being a Pennyroyal. This reminds me of a plant I had in use some half-dozen years ago for a similar purpose. I called attention to it at the time, and have seen no reason to depart from the good opinion I then held of it as a neat, dwarf, hardy plant of much beauty. It is a Thyme instead of a Mint, *Thymus (angustifolius) micans*. It is per-

fectly hardy, and better adapted for groundwork or covering a large space than for narrow lines, but it could easily be made to confine itself to the latter. It is a very neat-growing plant, and deserving of a place in every collection of alpine plants. *Sedum Lydium* used with me to have a brown, almost red, appearance; and it would appear to be still prone to assume that colour. The prettiest green cushion plant of years gone by was *Saxifraga Standishii*, an improved form of *S. cespitosa*, it being perhaps the prettiest green to be met with in autumn and winter; it is also suitable for summer if its flower stems are removed. I hope due attention will be paid to plants of this class by those having the means of doing so, as their diversity of form and other features entitle them to as much attention as is now devoted to Ferns.—J. ROBSON.

### THE AMATEURS' UNIVERSAL HAND AND WHEEL BARROW.

THE inventor of this barrow states that "all who have gardens and greenhouses and cannot afford the expensive luxuries of gardeners, and all who live some little distance from a railway station and are not able to keep a pony and trap, and cannot hire a conveyance, will find that the possession of such a barrow as here described and figured is a great acquisition, and after a short use almost a necessity."

Fig. 54 is an ordinary handbarrow, the use of which in conveying plants to and from greenhouses and at flower shows has ever been acknowledged; but as this necessitated the presence of a second person, which was often inconvenient to say no

Fig. 54.

more, a stout bicycle wheel (2 feet 10½ inches high) was added, also a pair of legs, all adjustable with the greatest ease, and then placing a shallow box (sides 4 or 5 inches high) upon the bed of the barrow. This—fitting into iron sockets, and being held firm with two pins attached to the tray, and going through the bed of the framework, and secured on the other side by

Fig. 55.

two nuts—forms fig. 55, and is for preventing flower pots from falling off. Let anyone wheel or two persons carry a few dozen plants in thumb pots without these sides over uneven ground and he will quickly perceive the advantage.

Fig. 56.—This is a deep box fitted to the framework exactly

Fig. 56.

in the same way as the shallow one, the deep sides being most useful for the removal of grass or leaves from a lawn.

Fig. 57 is a box about half the size of the last, similarly attached but of stouter make; this forms an ordinary wheelbarrow for light work, but it is better to have an ordinary wheelbarrow for rough work, as the tossing-over and too frequent use might damage the rest of the invention, which is con-

Fig. 57.

structed as lightly as consistent with strength, so that amateurs, gentlemen and ladies, and indeed children, can use it.

Fig. 58.—We now come to the greatest boon of the invention, especially to those situated more than a mile from a railway station, and having no carriage and great difficulty in hiring a fly. In lieu of the box we have merely a straight upright piece of wood to prevent, in the conveyance of boxes, port-

Fig. 58.

manteaus, &c., their rubbing against the wheel when going downhill. Owing to the size of the wheel and the extreme lightness of these barrows, if made by a first-class workman and of the right materials, much luggage can with the greatest ease be conveyed.

Any of your readers wishing for more minute particulars can apply, by forwarding stamped and directed envelope, to the Rev. T. W. Hathwaite, Buckwell, Bristol, by whom the barrow was invented and patented, and who will answer any questions.

The following weights of different parts may be useful:—Fig. 54, weight about 34 lbs.; fig. 55, 46 lbs.; fig. 56, 65 lbs.; fig. 57, 60 lbs.; fig. 58, 41 lbs.

### HOW NOT TO GROW THE ROSE.

NOTWITHSTANDING all that has been written in excellent and popular works on the Rose and its cultivation, notwithstanding the supplementary information given in your Journal week after week and year after year on the same subject, notwithstanding the high estimation in which this flower is held by the English public generally—notwithstanding all this, I cannot but think that a knowledge of even the A B C of the art of Rose-growing is confined to very few, considering that there is scarcely a garden in the whole country in which the Rose is not to be seen.

I hope I am overstating the fact, but I do not think that I can be doing so when I say that not one Rose in fifty is grown under conditions in which it could reasonably be expected, by anyone who understood anything at all about the matter, to yield even tolerably representative blooms. That here and again, under even the most unfavourable conditions, it will produce fairly good blossoms is a fact highly creditable to the Rose, as showing the extreme graciousness of our queen in thus condescending to confer her favours upon even the least worthy of her subjects.

I do not refer in the foregoing and following remarks to

those nurseries of the Rose where every attention is paid to the requirements of its early growth, and where Roses are reared annually by tens of thousands, but to their usual after-treatment in the gardens of the cottage, villa, country house, gentleman's seat, and nobleman's mansion. In some gardens of these classes the Rose is tended with more skill than in others; but as I do not wish to make invidious distinctions, I will say that in every class of garden without exception Roses are frequently to be seen growing in one or other of the three following positions:—

1st, And this is, perhaps, the most common. In the centre of a small circle cut out of the lawn, the remaining space of which is filled up with either spring, bedding, or climbing plants.

2nd, Another favourite spot is in the midst of a crowd of other flowers in a mixed or decorated border.

3rd, And lastly, and least frequently, on a lawn without any turf whatever cut away from around them. This is by far the most fatal position of all.

Whether this almost universal disregard to the first requirements of one of the most beautiful of flowers is due to indifference or want of knowledge I cannot say. I would much rather consider it to be due to the latter cause, and yet it seems to me most strange that cottagers, masters, and gardeners generally, should be so totally ignorant of this one prominent fact respecting the Rose—that even as the shark is one of the most voracious and insatiable of fishes, so is the Rose its representative amongst flowers. How, then, can such a beautiful but hungry creature be expected to retain health and vigour when condemned to feed for ever off the same small plate of food with a lot of other hungry little creatures?

Every one is aware that the queen of flowers has not pretty feet, but it may not be as generally known that they are, moreover, of so tender, and may I say gouty a constitution, that they cannot endure the pressure of even the lightest flower, much less of dainty-looking but far heavier turf. To my mind, this dainty grass would much more appropriately cover her grave—aye, and often does so cover it.

Then, again, how seldom are permanent labels attached to Rose trees in order to distinguish the different varieties. Now, can a rosarian picture to himself any more pitiable object than an indifferently grown Rose without a label? which to his eyes can appear nothing less than a heaping of the grossest insult upon the most unpardonable of injuries.

This deplorable condition of the kingdom of Roses to which I have endeavoured to draw attention is one which I think all true and loyal subjects of the Rose ought to do their utmost to rectify, both by precept and example, on every possible occasion that presents itself. Then if, in addition to this, our Rose nurserymen would, on sending out their Roses, enclose printed suggestions as to those conditions under which no Rose ought ever to be planted, they would, I cannot but believe, bring increased custom to their nurseries and greater credit on their Roses, to say nothing of the lasting benefit they would confer upon the Rose world.—E. M., *Croydon*.

### TRITOMAS.

It is at this time of the year, when nearly all kinds of flower-garden plants have ceased flowering, that we appreciate the beauty of Tritomas. The chilly autumn nights, which lay low the Dahlia and other favourite autumn flowers, have no injurious influence on the Tritomas, but on the contrary, their bright spikes appear to become a shade more vivid. They are none of those miniature or semi-invisible "bright gems of earth," which one has to bow the knee to admire. The large stately spikes of gorgeous orange, red, and green-coloured flowers of Tritomas are extremely effective. The plants are mostly grown in back lines in ribbon borders, and they suit this position admirably; but they are not so often grown as isolated clumps on the grass as they should be. For this purpose they are quite as useful and as becoming as the Pampas Grass. They—also like the Pampas Grass—have a grand appearance near the edge of lakes or rivers; and plants here and there in the shrubberies do not seem out of place.

My chief object, however, in noticing them now is to call attention to their propagation. The best time to increase them is in autumn. When the tops are cut down the roots should be lifted out of the ground and separated into small bits, when they should be potted singly and placed under cover in a frame for the winter. In spring they should be

allowed to start slightly into growth at both root and top before planting them out, and when this is done they go on without receiving any check, and make good blooming plants before autumn.

When the stock is sufficient it is not necessary to take the plants out of the ground every year, for they are more effective the larger they are allowed to become. They grow luxuriantly in rich soil, such as good loam mixed with manure. They will grow also in light poor soil, but they do not remain so long in bloom, and the flower spikes are not so large as those from plants grown in generous soil. I find the best varieties to be *T. uvaria grandiflora*, *T. grandis*, and *T. uvaria glaucescens*.—R. I. N. M.

### PLANTS OF THE PAST.

IN your "Notes and Gleanings" I observe the fine old plant *Witsenia corymbosa* is alluded to. This is one of the good old greenhouse or conservatory plants so seldom seen in modern gardens. There are many other old plants which are almost lost sight of in the rage for novelties. Another fine plant, *Tabernamontana coronaria*, noticed in your account of Wimbledon House, is a plant so seldom seen that many young gardeners know nothing of it. Another fine plant for effect as a stove climber, *Combretum purpureum*, is seldom seen; likewise *Petrea volubilis*, one of the rarest and most beautiful of stove plants. *Portlandia grandiflora* is also absent from many gardens. *Pleroma heteromalla*, *Mussaenda frondosa*, and *Pavetta caffra* are also gone from the general gaze. *Luculia gratissima*, one of our most beautiful and deliciously scented winter-blooming conservatory plants, is seldom grown, and when it is does not look happy. Some twenty-five years ago there was a fine plant on the back wall of the old conservatory at Arundel Castle. The then gardener, Mr. G. M'Ewen, was proud of it, and well he might be, for it covered a large space, and in its season was worth a ten-mile walk to see. *Mitraria coccinea* is out of fashion, I suppose; and where are the specimens of *Leschenaultias*, *Phenocomas*, and *Aphelaxes* as grown by Messrs. W. P. Ayres, W. Barnes, Green, Robertson, and their contemporaries? Why should not some of the horticultural societies offer prizes for threes or sixes of some of these old favourites, and so stimulate young gardeners of the present day to emulate those who have retired with their "blushing honours thick upon them?"

There are many other plants which could be named attractive and desirable. These old favourites have more or less given place to ornamental-foliage plants, which are as easy to grow as *Rhododendrons* at Knap Hill. I will own they are beautiful, but not such masterpieces of plant-growing as the collections shown by the plant-growers in the palmy days of Chiswick. Such specimens of those days required close attention, and the most patient and painstaking carried off the honours. Now, with plenty of glass, pot-room enough, and a liberal supply of liquid manure, nineteen out of twenty of the foliage plants may be grown as freely as Laurels, and those with the most room and largest place carry off the prizes.—J. GADD, Thorndon

## GATHERING THE CHAMPAGNE GRAPES.

WITHIN an easy distance of the town of Rheims, and connected with it by a convenient railway, will be found the various localities which yield the Grapes from which the popular wine called champagne is made. Covering all the hills and scattered about the plains, occupying every square foot of available space, the Vine steadily asserts itself, and, despite the monotonous regularity of the rows, the straightness of the intersecting avenues, and the millions of light grey short sticks to which the Vines are attached, it would be unjust to deny the existence of a certain picturesque effect. The gentle undulation of the soil about Reims considerably favours the growth of the Grapes. All the Vine gardens obtain the full force of the sun, and it may be safely said that they obtain a maximum of heat and a minimum of shadow. The land in France is so very valuable, and the system of peasant proprietorship is so usually followed, that we find in the neighbourhood of Rheims a general and equal division of space.

It is commonly but erroneously supposed that each particular brand of champagne is made from the Grapes grown on one vineyard, and, further, that every proprietor makes his wine from his or her own ground. This is by no manner of means the case. The Clicquots, the Moets, the Mums, the Roederers, the Goulets, and the Pommerys all have special tracts, and naturally employ their own Grapes; but at vintage time it is necessary to buy liberally from the humbler growers in order to meet the demands of their gigantic establishments. There is another reason why there should be a mutual exchange of the champagne fruit. This popular wine only obtains its perfection by a careful, artistic, and judicious mixture of juices obtained from first-class vineyards. It is said that among these Ays is renowned for the sweetness of the Grapes; Cramant for its sparkling properties; Verzenay for bouquet; and Bouzy for force or *vinosité*. Doctors differ on the subject of these mixtures. Some manufacturers insist upon carefully divided proportions of Sillery, Verzenay, and Bouzy; of Mareuil, Ay, and Dizy; and Pierry, Cramant, Avizi, and Mesnil; whilst others content themselves with Ay, Pierry, and Cramant. Be this as it may, the true art of champagne-making is in the mixture of the various qualities when the fermentation of the wine in cask is complete about Christmas time. It requires a careful intelligence to buy judiciously at the time of the *vendanges*, and to prophesy correctly concerning the ultimate value of the perfected Grape; but the great art is when the proportions of fermented juice are poured into the huge mixing vat in the cool cellars of the manufactory.

I was struck with the cleanliness, decorum, and cheerful character of all employed on the various vineyards I have visited. There was no noise or disturbance anywhere, and wherever I found the labourers, hard at work among the Vines, dressing the Grapes for the press, or returning from their work, there was the same order, civility, and frequent merriment. The adjacent towns, villages, farms, and barns fairly accommodate this influx of visitors, and, so far as I could see, there were no signs whatever of drunkenness or disorder. The pickers are summoned by beat of drum at daybreak each morning in the market-place of the villages adjacent to the vineyards, and then and there a price is made for the day's labour. This varies according to the work required to be done and the speed with which it is necessary to accomplish it. The bargain struck, away go men, women, and children into the vineyard, each provided with a small basket and a pocket knife, curved like a reaping hook. They are divided into gangs, each headed by an overseer, and as the small hand baskets are filled they are carried to the end of the row, where specially selected hands are employed in what is called dressing the

Grapes for the press. In what are known as good years this operation is considered useless, and the manufacturer is compelled to purchase the vintage, good and bad together, just as it comes from the field. But any such reckless system is utterly impossible in most of the vineyards this year. At Verzenay, for instance, will be found a considerable quantity of rottenness, much worm-eaten and mildewed fruit, which if pressed in its present condition would assuredly have the effect of tainting the wine. So the system of dressing, happily for the manufacturer, is almost universal.

Each bunch as it is tumbled into the crate at the side of the vineyard is carefully gone over by female fingers; the bad and cankered parts are rejected, diseased stalks are pruned away, and some attempt is made to send the Grapes to the press in a decent condition. But even this hurried inspection is not all that could be desired, and the sharpest eye is apt to be deceived, particularly in the Verzenay vintage of this year. We frequently discovered in the very heart of what looked a regular and well-grown bunch, a Grape or so absolutely rotten and capable of infecting its companions when they were heaped together in the press. The dressed fruit, when carefully finished and inspected, is quickly borne away in carts to the nearest press, usually situated in the village, and the refuse remaining represents the loss in quantity to the proprietor. The general colour of the Grape in the Rheims district is black; but there are celebrated vineyards, such as Cramant, which only grow white Grapes. It will occur, doubtless, to someone to ask if the labourers are permitted to go upon the old hospitable principle of "eat what you like and pocket none." Nearly every sensible proprietor places no restriction on the obvious temptation of the enjoyment of ripe Grapes on a hot day. It is found far the most economical plan in the end, for the first day's debauch ends in such serious inconvenience, and very often loss of wages, that the Grapes are left alone from that moment. Women and children are found to be the most skillful pickers, and the men are for the most part employed in carrying the baskets to and fro, emptying the crates, and loading the waggons.—(*Daily Telegraph*.)

#### HARDY AUTUMNAL FLOWERS.

As Mr. Taylor in the *Journal* of October 12th asked for information respecting hardy flowers, I wish to endorse all he says respecting their beauty and utility at any time of the year, but more particularly now that the more tender occupants of the garden are becoming scarce.

I have a few plants in bloom now which he does not mention; they are *Pyrethrum uliginosum* (a truly grand plant), and several other varieties both double and single; *Rudbeckia Newmanii*, a gem of the first water; *Eriogonum grandiflorum*, *Astrantia carnioica*, *Delphinium* in variety, *Schizostylis coccinea* now coming into bloom (October 27th), and is most beautiful. *Tropaeolum speciosum* is now going out of bloom.

I do not remember ever seeing so many herbaceous plants in bloom so late as this before.—E. SENDALL, *Gardener, Barningham Hall, Hanworth, Norfolk*.

#### THE INNER TEMPLE CHRYSANTHEMUM SHOW.

WHEN a display of flowers like the one now open to the public can be produced in the heart of the metropolis, it is a proof alike of the great value of the Chrysanthemum as a town plant, and of the skill of the gardener in bringing out its beauties so fully. It should be remembered, however, that Mr. Newton does not attempt to grow symmetrical plants, but only fine blooms, and in this he succeeds.

There is no wonder that vast crowds of Londoners and London visitors avail themselves of the kind privilege accorded by the Benchers of enjoying the fine autumn display, for it is certainly worthy of inspection by all who love flowers, and if there are any who do not we advise them to go for the purpose of being converted. We knew of a prize-fighter who went to a Rose show and was conquered and himself became a buyer of new Roses, a grower and prizewinner, and from that time took no more interest in ropes and stakes except for supporting the flowers by which he was vanquished, and which perhaps even now he continues to nurture. It is not, therefore, even those who delight in flowers but those who have not yet been enabled to appreciate their charms whom we advise to visit the Inner Temple Gardens during the early part of the present month.

The show is, like other shows of the past, a simple bank of fine flowers, the plants being from 5 to 7 feet in height, and about four hundred in number, all grown on single stems, each plant supporting three to six blooms. There are, in fact, four close rows of plants extending a length of 50 yards, protected by glass with the front sheltered by a screen of canvas. It is the seventh show under Mr. Newton's management, and is superior to most that have preceded it, and inferior to none.

Only a few of the most striking of the eighty varieties can be noticed, commencing with those of recent introduction. One which cannot fail to strike the eye of most visitors is named "Newton's Inner Temple." This is purplish crimson in colour, the exterior of the petals having a lilac tinge. It is a bold firm flower of great substance of petal, and is slightly incurved. It is an acquisition for its rich colour, but would be more valuable were its petals of greater length. It is perfectly distinct from any other variety in the show, and fine as it is now, it is possible that it will improve in future years. Another new variety of undoubted merit is Mrs. Dixon. This is a golden sport from George Glenny, which in turn came from Mrs. George Rundle. The three are identical in character and form of flower, Mrs. Dixon being a bright glossy yellow. This is a trio of Chrysanthemums which in their colours—white, sulphur, and yellow—are for general decorative purposes probably unequalled. Rather small, perhaps, their flowers may be, but they are constant in their excellence and are freely produced. The next variety to notice is Mrs. George Parnell. This may be described as an enlarged form of Mrs. G. Rundle, from which it is really more dissimilar in foliage than in bloom. Mr. G. Parnell, we believe, received a first-class certificate last year at the Royal Horticultural Society, and is a variety which must be grown by all exhibitors.

Refulgence, which was exhibited for the first time last year, is the richest of all in colour and has improved in form, but it is clear that high culture is requisite to "fill" the flower and close the yellow eye. When that is accomplished none can deny its excellence. Other highly coloured flowers are Mount Etna and Count de Ranzeau, which are reddish crimson but imbricated; Garibaldi, chestnut, is very rich; and particularly attractive is King of Denmark, rosy lilac with orange tips. Prince Alfred is the largest of all, but there are almost equally fine examples of Nil Desperandum, Hercules, Prince of Wales, Alfred Salter, Golden Eagle, Ossian, and Jardin des Plantes. Amongst the lights White Globe has the finest blooms, and very superior also are White Beverley, Vesta, Mount Edgecombe, and Princess of Wales, the two latter being tinted with rose.

In the Japanese section Elaine is the most conspicuous, and a few blooms are to be seen such as have never been surpassed. James Salter, Fair Maid of Guernsey, and Garnet are also well represented.

In the outside border is a good display of Pompons, the most effective being the three Cedo Nullis, Florence, Madame Martha, Madame Tipping, and Aurora Boreale.

The thanks of the public are due to the Hon. Society of the Inner Temple for their liberality in providing this display through their able gardener Mr. Newton.

#### THE ROSE ELECTION.

FIG! FIG! "WYLD SAVAGE." What can be the matter? Had something marred thy digestion, or a recalcitrant nonconformist roused thine ire? Or it is, maybe, a spice of thine earliest ardour, when with lance, and sword, and sabretash thou wast ready to confront all the foes of perfidious Albion. Whatever it was, never didst thou better deserve the title which thy neighbour gave thee. One can almost hear the war shout, imagine thy fair face tattooed, and see thee devoting poor "J. H." to the dire punishment of the Furies. But it is too bad. Here is a gentleman, who amidst the duties of an arduous profession, the most arduous that a gentleman can fill, for the benefit of the Rose world devotes an immense amount of labour, time, and a good deal of expense to what to him is no doubt a labour of love; and yet my good friend heaps on his devoted head all kinds of sarcasm, and calls the election abominable, misleading, &c. Now on the other hand I, with a few more grey hairs on my head than "WYLD SAVAGE," say that the very warmest thanks of all Rose-growers are due to Mr. Hinton (whose hand I have never had the pleasure of shaking) for the pains and intelligence with which he has carried out the plan; the result, I believe, when carefully studied will be an immense boon to all Rose-growers.

And now to examine "WYLD SAVAGE's" tirade. He seems

to me to look at the whole matter as an exhibitor, but that was not the intention of "J. H." It was not certainly my notion in giving in my list. The wish was to give a list of the best Roses, and this accounts, I think, for the position assigned to Gloire de Dijon. It is true, as an exhibition Rose it is rarely up to the mark, but as a garden Rose in all soils, situations, climates, what can touch it? If I had to grow but one Rose old Gloire would be my choice. For the same reason I imagine Comtesse de Chabrillant occupies a low position. Exhibitors have not included her because she is small; but barring that it is the perfection of a Rose, and I would give her a foremost place on that account alone. For the same cause—usefulness in a garden, I imagine Souvenir de la Malmaison is placed where it is.

Another point that "WYLD SAVAGE" entirely overlooks is the effect of situation and climate. Some Roses which he names and the merits of which he thinks have been overlooked are doubtless gems, but it is not given to everybody to be in a charming spot where Teas grow like weeds, and hence Marie Van Houtte, Belle Lyonnaise, and Catherine Mermet will not do with everybody as they will with him. And the same remarks apply to H.P.'s also. Duke of Wellington is no doubt a grand Rose, but then it will not grow in many places, and it is not everybody who can afford to grow and throw away every year. Nor is Madame Charles Wood, over whose neglected charms "WYLD SAVAGE" mourns, a Rose the vigour of which we can rely upon. I do not quite understand what he means about Céline Forestier, whether surprised at the position she occupies or regret that she does not take a higher one; as an exhibition Rose she is difficult to catch, but as a garden Rose how lovely it is!

But then the list is altogether a failure because Hercules has not given in his names! One might imagine (only that no "she" could write thus) that it was Omphale mourning over her neglected lord; but he is rather like the carter in the old fable, whose cart was stuck in the mud, and who stood wringing his hands and calling out Hercules! Hercules! to deliver him. I rather imagine, from what I know of the muscular hero, that it was not because he foresaw a failure that he did not give in his list, but because he has a great objection to wielding the pen. There is no one for whom I entertain a greater regard than the said Hercules. I believe him to be a very champion, but then I know also all his growing has exhibiting in view. He resides in a climate where there is but little to contend with in the way of weather, and hence his list might have disadvantages to many.

But the next charge is the strangest of all—that the lists are sent in by nobodies, that we are no better than the clodhoppers in a village alehouse, &c. Now in the lists of amateurs I see such names amongst amateurs as Christy, Peach, Camm! Mayo, Beachey, Cheales, Laxton, and Jowitt, men who are most of them exhibitors, and have, if I mistake not, knocked "WYLD SAVAGE" out of time more than once; and find that amongst professional growers Cant, Cranston, Curtis, G. Paul, Prince, and Turner have given in their lists. I hold my breath in astonishment at the "WYLD" rush of the Savage, and wonder what he wants.

And then as to the blunders about names of raisers. "J. H." deserves our best thanks for endeavouring to supply them, and it was not to be expected that it would not be imperfect. As to Marie Cointet (which most people find too delicate to be a gem of the first water), Mr. Bennett certainly was not its raiser; but had it not been for him I think it would have been consigned to the "tomb of all the Capulets." It had been passed by until he brought it forward. If "J. H." has any difficulty about raisers' names I fancy Mr. Cant could help him, as I remember years ago seeing with him a note-book in which each year's new Roses were inserted with the names of the raisers, and he may have it yet.

I hope "J. H." will not think "WYLD SAVAGE" a representative man on this occasion. I hope he only represents himself, but that most of us thank him heartily for his work.—D., Deal.

"WYLD SAVAGE" certainly writes as though he was civilised, to an extent perhaps influenced, or probably limited, by the nature of the soil he lives on. To think that he should debase the character of my charming Gloire de Dijon, which gives me innumerable perfect blooms twice in the year, while others will call this Rose "Glory Die-John" and "Glorie-dee-die-John."

I have seen the results of the Rose election, and believe that each list is the conscientious opinion of your correspondents.

Mr. Hinton need not be alarmed at differences of opinion. I certainly dislike that coarse Paul Neron, and should have excluded him as quite unfit even for the company of Gloire de Dijon. I can also imagine that some of your voters have not had sufficient experience of Beauty of Waltham, Duc de Rohan, and Belle Lyonnaise, to recommend them in their list; or can it be that these have been tried, and are not good with them?

It is not every season that I buy new Roses, and then only to fill up; and although I watch your weekly issue with keen interest for all the news, and even anticipate your election by my own private election list for comparison sake, I too can differ in some respects with the result, principally through old favourites giving place to new varieties; but then, is it possible to obtain fifty people growing Roses in different soils, atmospheres, and circumstances, of one opinion respecting some Roses, and particularly new introductions?

Frequent disappointments have cooled my ardour, and now I never buy new Roses until they have gained honours in the prize list.—MARIE VAN HOUTTE.

"CONSIDER YOURSELF, sir, well sat upon." And so I do, and know also that I have yet further condemnation to expect from private letters I have received; but yet in self-defence I must say one word more. I had not the slightest idea when asked to send in a list of Roses that such Roses were not to be selected as exhibition sorts. If I had known that the best Roses for general purposes were meant I should have had nothing to do with the election. I grow Roses for exhibition, and not for decorating my garden, or for ladies and children to run about among them with a pair of scissors cutting here and snipping there, and detesting the very idea of disbudding.

As a garden Rose the "Gloire" is no doubt a grand Rose in its way, but infinitely surpassed even in this light by Madame Trifle, Belle Lyonnaise, and Madame Berard. Whatever condemnation I may meet with from the rosarians who have written or may yet write to you on the subject of the Gloire as an exhibition flower I care not so long as I have such an authority on my side as Mr. Benjamin R. Cant. I think it will be allowed by all that no other nurseryman shows the Tea Rose in such perfect form and colour as the great Colchester rosarian, and yet he does not place the Gloire in the first fifty. Mr. Corp of Oxford, and Mr. Fraser of Lea Bridge, also exclude it, so that I am by no means alone. I am much interested in the lists, and have my mind now set at rest as to what nurserymen excluded Charles Lefebvre from the first twenty. I see they are Messrs. Ewing & Co. of Norfolk, who of course place Gloire de Dijon in that exalted position.

The table published by Mr. Hinton in last week's issue is a most interesting one, and although he may point to its bearing out his views I may also do the same. Duke of Wellington in this list is 27; in the former list he was placed 39th. However, after all, as Mr. Paul so well shows, it is impossible to arrive at any real judgment of the qualities of the Rose, for what will flourish in one soil will scarcely live in another.—WYLD SAVAGE.

### WEYBRIDGE.

LAST year I gave a few hurried notes of a visit I paid to Weybridge Heath on a very wet day, and of the interest which there is to the horticulturist in the gardens of Dr. Henry Bennett and Mr. G. F. Wilson. This year, under more favourable circumstances, I was enabled to repeat my visit and to add to it another—that of the famed garden of Mr. McIntosh of Duneevan, and perhaps a few additional notes on them may not be unacceptable to the readers of our Journal.

No three places could give, I think, a better idea of the horticultural zeal of our nation and of its varied character than these I have mentioned. They are all small—merely the gardens attached to villa residences, and all essentially different. In the garden of Dr. Bennett we have the refined taste and love for elegancies which mark the travelled and accomplished physician (not forgetting the *placens uxor*), where all inside the house and in the garden tell of how much stress is laid on that which is pleasing to the eye and in accordance with the strict principles of taste. In that of Mr. G. F. Wilson we have that of the enthusiast, whose object is to gather together the choicest and best of the plants he loves so well, and to be more interested in their successful culture than in the effect produced as a matter of taste; while in that of Mr. McIntosh we have the carrying-out in its fulness of the culture of one or

two specialities, which make the grand feature of the place; yet all three in their way have a beauty of their own, and to one who, like myself, is bound by no limits in horticulture, all were attractive.

I last year, in mentioning Dr. Bennett's pretty residence, alluded to the manner in which he has made innovations on old-established ways of doing things: that the Heather which forms the groundwork of his wood garden, instead of being allowed to grow long and lanky is kept close cut, and presents a beautiful carpet of purple bloom, the idea being borrowed from patches in St. George's Hills, which he found apparently nibbled by rabbits and throwing out their shoots abundantly, instead of, as in ordinary cases, merely coming out at the end of the blooming branches. This year it has made still further progress, and after a time will, I am sure, fulfil his expectations. He has this year introduced another innovation—namely, planting some creepers at the base of the trees, and thus covering the stems with bloom. We know how completely this is the case in tropical climates, and I am sure that to see Clematises of various colours, *Bignonia radicans* major, and other climbing plants throwing out their shining blooms along the stems and among the branches of our trees would be a pleasing sight, and I hope in a small way to try it myself. I was particularly struck, too, with the effectiveness of the large *Fuchsias* grown in pots and standing outside the house. Their branches heavily laden with blossoms of various colours and their graceful habit fit them admirably for such work. The difficulties in the way of Dr. Bennett's gardening are manifold, arising from the fact that he is here for only four months, and that his heart is with his Mentone garden, and that for during eight months he is obliged to leave all at The Ferns in the care of his gardener. Yet no one coming upon it as I did in the month of September would believe either that this was the case or that the whole house had been dismantled; but so it is, and the able superintendence without and the deft hands within soon bring beauty out of disorder, and make one wonder that it could ever be otherwise than we see it.

Mr. Wilson's pretty place, Heatherbank, is, as all the gardening world knows, the home of everything that is rare and beautiful amongst herbaceous plants and Lilies, and the marvellous manner in which they grow here reflects the utmost credit on his skill as a cultivator. We all know how he astonishes us sometimes at the Royal Horticultural Society with some new Lily or some favourite herbaceous plant, and here every nook in the garden shows how thoroughly they are at home. It was too late to see the garden in its beauty, but where herbaceous and alpine plants are grown there is always something of deep interest. Amongst these I noticed the rare and beautiful *Omphalodes Luciliae*, fine pieces of *Colchicum speciosum* and *Crocus speciosus*, the *Anæctochilus*-like *Goodyera pubescens*, *Soldanella Wheeleri*, *Gaultheria procumbens* growing quite rampant, *Dahlia glabrata*, *Fragaria indica*, *Vitis heterophylla*, *Rhododendron præcox superbum*, *Anemone japonica hybrida*, *Gypsophila prostrata* and *G. Stevensii*, *Gentiana asclepiadea*, &c.; while in the houses, waiting for their turn of potting, which Mr. W.'s zeal on behalf of the poor Royal Horticultural Society had hindered, were quantities of Lilies, *Calochortuses*, *Cyclobothras*, and all rare and curious bulbs in which their owner delights. The one great point of novelty was, however, Mr. Wilson's tank, which he has already described in these columns, and in which I saw many aquatic plants doing admirably on their little floating islands. The plan is evidently sound, and I have no doubt admits of many modifications more or less ornamental.

We have all heard of the wonderful examples of *Lilium auratum* at Duneevan, and I had received many a courteous invitation from Mr. McIntosh to see them or the *Rhododendrons* when they were in bloom. This I was unable to do, but I could not be in the neighbourhood without seeing the place where they grow; and well worthy is it of a visit. It stands in Oaklands Park, and the ground slopes down from the house to a piece of water, called here the Broadwater—in fact a large long pond. Every advantage has been taken of the nature of the ground, and masses of *Rhododendrons* are grouped in every direction, containing the very choicest and best of the sorts in cultivation. Among them in all directions were Lilies, some 11 and 12 feet high, carrying sixty or seventy blooms, and displaying a vigour which I think we may venture to say they have never attained in their native habitat, and compelling me to say, Well, I must come and see these in flower. But although Mr. McIntosh excels in these two specialities, yet his

garden contains many other things which are worthy of notice. Does he grow Roses? Well, in answer to this just let me say that in one of his rooms is a table on which there are arranged 250 specimen glasses of various sizes, and that these are kept filled all through the season with single blooms of Roses; and I rather imagine that anyone who can do this must be able to grow Roses. Like Charles Waterton Mr. McIntosh makes friends with the feathered tribes of his garden. A robin flies up and takes a crumb from between his lips, and a chaffinch is very nearly as tame. All who have met him will not wonder at this familiarity. I have rarely seen a small place where so much is made of it by judicious landscape gardening. Standing at the top of the terrace it seems large in extent, and everywhere fine trees and shrubs meet the eye; and if I am spared for another year I hope to visit it when either one or other of the specialities of the place are in flower.—D., Deal.

#### ACACIA RICEANA.

*ACACIA RICEANA* I consider the most beautiful and useful of the entire genus. It is much more graceful in growth than *A. longifolia*, its branches being very slender, and are elegant by their drooping habit. When planted out and allowed plenty of headroom this *Acacia* quickly assumes a tree form, and a more handsome tree it is impossible to conceive. I have also found it exceedingly well adapted for a pillar plant. Its beauty is never seen to greater advantage than when allowed to grow unmolested—that is, without being cut or tied into any stiff form. The flowers are pale yellow or lemon-coloured, and are produced in long pendulous festoons, and however ornamental they may be on the plant, they are none the less so in a cut state, and for this purpose alone it is worth growing in quantity. I may further state that although it succeeds best planted out, it also submits readily to be grown in either large or small pots.—N.

#### FLOWERS OF ROSE TREES SMALL.

I HAVE a lot of Roses on the Manetti four years old, which still grow well and flower well, but the blooms are small and lack substance. They have been dressed each year with plenty of fresh rich loam, the top spit of good feeding land mixed with old pig dung and night soil; and as my soil is rather light they have had a good mulching applied in May of littersy stable manure. Must I part with my old favourites, or can I restore them by taking them up, root-pruning, and planting in some new ground just enclosed from a pasture field? I always prune closely in March.—MIDLAND COUNTIES ROSE-GROWER.

[I should take up all the old Roses, and not only prune the roots but cut off the old Manetti stocks, for in most, if not all, cases the four-year-old Manetti Roses will have rooted themselves so well above the junction of the scion and stock, that the foster-parent can be discarded and the nurslings walk and do well on their own legs. In case, however, where these roots are not sufficiently strong it would be better merely to prune the Manetti roots and plant in fresh ground. If the grower could regard with indifference the quality of the blooms from those plants for one year, I should recommend him to give them a year's rest. Do not manure the ground, and do not prune the plants, but leave the Roses to grow and form fresh roots; then next year cut very hard indeed, and send them along with every kind of forcing manure applied on the surface, and I shall be very much surprised if those plants do not give him wonderful blooms. If, however, he cannot give them a year's grace, let the manure be put on the surface after planting and forked lightly in after pruning in March. —WYLD SAVAGE.]

#### EARLY WRITERS ON ENGLISH GARDENING.

No. 21.

SIR WILLIAM CHAMBERS.

SIR WILLIAM CHAMBERS, of Scottish parentage, was born in Sweden in 1726, but came to England when only two years old, and was placed at Ripon School. On arriving at manhood he became supercargo of a Swedish East India ship, and made one voyage in that capacity to China. On his return he commenced the study of architecture under the patronage of Lord Bute, by whose interest he was appointed drawing master to the Prince of Wales, afterwards George III. His first architectural erection was a villa for the Earl of Besborough at Roehampton. He was afterwards employed in laying out the Royal Gardens at

Kew, where he introduced the Chinese ornaments. In 1771 he was invested with the Swedish order of the Polar Star. He became a Fellow of the Royal and Antiquarian Societies. In 1775 he was appointed to conduct the erection of Somerset House, being Architect to the King, Surveyor General to the Board of Works, and Treasurer of the Royal Academy. In 1758 his style of design, &c., was severely attacked in two satires termed "An Heroic Epistle," and "An Heroic Postscript to Sir W. Chambers." In that Heroic Epistle is observed that "he teaches us that a perfect garden must contain within itself all the amusements of a great city; that *urbs in rure*, not *rus in urbe*, is the thing which an improver of true taste ought to aim at."

"To Richmond come, for see, untutor'd Brown  
Destroys those wonders which were once thy own.  
Lo, from his Melon ground the peasant slave  
Has rudely rush'd and level'd Merlin's cave:  
Knock'd down the waxon vizard, seiz'd his wand,  
Transform'd to lawn what late was fairy land."

The volume which entitles him to our notice is entitled "Plans, Elevations, Sections, and Perspective Views of the

Fig. 59.—Sir William Chambers.

Gardens and Buildings at Kew in Surrey, the Seat of H.R.H. the Princess Dowager of Wales. 1763." In the introductory description of the plates is mentioned that Mr. Kent designed some of the ceilings and chimney-pieces. Sir William remarks that "the situation of the gardens is not advantageous, as it is low and commands no prospects. Originally the ground was a dead flat, the soil in general barren and without either wood or water. What was once a desert is now an Eden. The judgment with which art has been employed to supply the defects of nature and to cover its deformities hath very justly gained universal admiration. The orangery or greenhouse design is mine, and was built under my inspection in the year 1761. The physic or exotic garden was begun in 1760. For the cultivation of the plants I have built several stoves." The thirty-ninth plate is of the aviary and flower garden.

Sir W. Chambers died March 7th, 1796, at his house in Norton Street, London, and was buried in Poet's Corner, Westminster Abbey.

#### ASPECTS OF NATURE.—OCTOBER.

OCTOBER is the last month of the year when Nature is decked in gay attire, and then it is not the gorgeous hue of flowers that enliven the landscape, but the rich and manifold tints of daily changing foliage, which contrast so charmingly with the sombre hue of the Pines and other evergreen trees. Rich red, deep golden brown, and russet green, the leaves still hang on the trees or tremble downwards to the earth, where they lie in

copse and forest in deep layers, covering the numerous wildlings that have rendered the earth gay and beautiful with their spring and summer blossoms. But it is not alone the leaves which light up the sober autumn landscape; the rich ripe berries of hedgerows and trees are now fully displayed through the hourly thinning foliage. Conspicuous among them all is the Mountain Ash, which often grows in the clefts on the sides of old quarries, or in fissures on the hill side, hanging over precipices, and appearing far up the mountain. With berries almost as brilliant as those of the Mountain Ash the wild Guelder Rose is found by the margin of streams and in moist situations, where its scarlet and orange fruit is conspicuous in rich wax-like clusters, and contrasts beautifully with the purple-black berries of the Privet; indeed, at this season the hedgerows are as gay, or even gayer, in many places than in summer. In favoured spots the graceful Berberry puts forth its pendant rosy berries, and on every side may also be seen the rich scarlet clusters of the Honeysuckle and Deadly Nightshade, while the fruit of the Bryony changes gradually from bright green to scarlet, and then to black.

In many of our southern counties where Oak trees abound the gathering-in of the acorn harvest is now in full vigour, and merry parties of women and children sally forth in the early morn with bags and baskets to gather up a store of winter food for their pigs. A moderately high wind after a frost will cause the coveted acorns to patter down thick and fast upon the fallen leaves. The Beech tree also drops its triple-sided nuts, the kernels of which are eagerly sought by the rapacious wood pigeon. The beautiful, smooth, glossy fruit of the Horse Chestnut, untouched by any other animal, is found palatable by the herds of deer that roam over our ever-verdant parks; and the numerous birds that made the air vocal with melody in spring now find a continued feast on Hawthorn bush and Briar. The berries of the Thorn are but little more brilliant than its deep rich red leaves, and these in many places are almost hidden by the trailing Brambles, which still keep a store of slowly ripening fruit, and make long garlands of exquisitely diversified foliage over bank and fence, often disputing the mastery with the rampant growth of the wild Clematis or Traveller's Joy, which is now covered with its downy silky tufts of seeds. Less conspicuous, indeed, from their position, but none the less gorgeous, the lanes and hedgerows vie in beauty of colour with the forest trees, whose

"Virgin leaves, of purest vivid green,  
Which charm'd ere yet they trembled on the trees,  
Now cheer the sober landscape in decay.  
The Lime first fading, and the golden Birch  
With bark of silver hue; the moss-grown Oak,  
Tenacious of its leaves of russet brown;  
Th'ensanguin'd Dogwood, and a thousand tints  
Which Flora, dress'd in all her pride of bloom  
Could scarcely equal, decorate the groves."

But although the beauty of the foliage attracts our attention before anything else at this season of the year, we still have many flowers, but they are small and scarcely to be compared with the fulness and abundance of summer. Foremost among the wild flowers is the Meadow Saffron, or Colchicum autumnale, which decks our fields in the eastern counties when almost the last lingerer of the floral year has departed. Pale her blossoms may be, and unprotected by foliage, but still the very delicacy of this lovely flower, "the orphan of the year," has something in it which reminds us of spring, the flowery joys of which are so lately past that they still linger fondly in our memory, and which a few short months shall bring back to us again ever fresh and new. In winter the seeds lie buried deep in the earth, to burst forth into life and beauty during spring and summer. The seeds of the Meadow Saffron form no exception to the rule; they, too, are buried during winter, but they lie in their bed even when other plants are springing into light and life. It is then that the seed of the Saffron is lifted on a fruitstalk up to the air and sunshine, which ripen and perfect it; and when in the bright and balmy days of June the hay harvest is ready for gathering, the capsules of the seed vessel crack and the seed is dispersed. Thus in the case of the Colchicum the prevailing rule of Nature is changed: the plant blossoms in autumn, and produces its leaves and fruit in the following spring.

Barren as the meadows and lanes appear to a casual observer, we have still many flowers in secluded sheltered spots. Not only does the hardy Cranesbill bloom, but the white Clover is found growing spontaneously in many places which would otherwise be bare. Some say that the white Clover represents the national emblem of Ireland, the three-leaved Shamrock;

but I always understood that the small yellow Trefoil which bears a very small blossom in waste places and little-frequented fields was the true symbol of Ireland, the finding of a leaf having four segments being considered a piece of luck insuring lasting happiness to the finder.

"I'll seek the four-leaved Shamrock  
Through all the fairy dells,  
And if I find the treasure,  
Oh! how I'll weave its spells."

Even at the very end of the month some plants still put forth flowers. The little modest Chickweed blossoms in autumn as in spring, pushing its tiny leaves through the earth and forming a verdant carpet in every available spot. The Daisy, too, we have always with us; less numerous than in summer, "the wee crimson-tipped flower" still "cheers chill October on its way." It is true

"We look abroad into the world, and see  
But few familiar faces peeping forth  
From hood or mantle. Spring's bright flowery train  
And Summer's matron sisters, Autumn's too,  
Are mostly gone; yet still in mead or glen  
Linger some loved ones, smiling to the winds  
That come and go, and hurry forth sere leaves  
From out their haunts."

And even now we find many charms in country rambles. The commons are still bright with a covering of golden Bracken, and here and there the purple Heath has not quite faded from the moorland, and the now sparse blossoms of the golden Gorse speck the open landscape, while

"The fading many-coloured woods,  
Shade deep'ning over shade, the country round  
Imbrown'd; a crowded umbrage, dusk and dun,  
Of ev'ry hue, from wan declining green  
To sooty dark."

—T. S. J.

### JUDGING VEGETABLES.

MANY thanks to Messrs. Taylor and Fairweather for introducing this subject for discussion in the columns of your Journal. Mr. Fairweather concludes by calling on those able to discuss the question. I, for one, do not presume to respond in the above terms; but as the matter has given me much thought, I would on this occasion avail myself of the opportunity of stating my opinions.

Mr. Fairweather cites a case where Cucumbers, Tomatoes, and Vegetable Marrows in a collection beat Potatoes, Peas, and Cauliflowers. I admit there is great difficulty in judging collections where the exhibitor can put in what he likes, and where nearly all the collections are different; but this could be amended. In the exhibitions of fruit who would think of staging a collection in September without having Grapes, Peaches, Pears, Apples, Plums, and a Melon? Now I think this is pretty generally understood. Then why not with vegetables have five or six of the leading and most useful kinds, and let the rest in the collection (as in the fruit) go for what they are worth?

There are one or two more points in judging I would like to call attention to. There are few who have attended shows and paid close attention, but who have been struck with the nature of the awards. I have seen Peas not at all fit for table use placed first instead of Peas of superior merit, because the former was a newer variety. Again, in Potatoes, I have seen a dish of large but ill-shaped tubers placed first, when another dish of the same variety, well shaped, of medium size was placed second. Cauliflowers, too, I think are often imperfectly judged. Large heads—simply because they are large—are placed first, when smaller compact heads of superior quality are passed over. Beet is another vegetable the merits of which are not always recognised. I have seen first-prize roots little better than Mangold Wurtzels, while smaller roots sweet and young were lying on the same board dishonoured. Prizes are generally offered for the best six or twelve Onions. A good Onion ought, in my opinion, to be solid, well ripened, of good form, thin-skinned, and without neck. Onions of this description I have seen exhibited against others twice as large, with white roots sticking to them, with necks projecting 2 or 3 inches, and the large specimens were placed first. I conclude by desiring that less attention be paid to mere size, and more to real quality in the judging of vegetables.—B. G., Co. Down.

### FLOWERS IN LIBERIA.

MOST of the African flowers differ from those of temperate climates in three striking characteristics—viz., brilliancy of

colour, luxuriancy of growth, and in emitting their odour after sunset.

The last peculiarity has been admirably described by Moore in speaking of that lovely native of India—the fragrant Jasmine—

"The flowers that wake while others sleep,  
The timid Jasmine buds, that keep  
Their fragrance to themselves all day,  
But when the sunlight drives away  
Let their delicious secret out."

A rare and very beautiful species of the Jasmine grows in our African forests. The bushes sometimes rise to the height of 10 feet, and are densely covered with large, pinnate, oval leaves. The starry white flowers, with bright pink stems (clustered on what botanists term a cyme), raise their delicate heads in striking contrast with the heavy masses of glossy dark green leaves. Their fragrance is delightful. If we happen to awaken at night in a room where a sprig of this odorous flower has dropped, we are almost inclined to imagine that, instead of the dreadful malaria we strive so much to keep out,

"The sweet south wind  
That breathes upon a bank of Violets,  
Stealing and giving odour."

has, by some miraculous means, penetrated our closely-shut African chambers. Most aptly did the ancients call this sweet flower the "Odorous Violet."

So much has been written about the majestic Lilies of the tropics that it is only necessary to say that many finer varieties flourish on our coast. Perhaps the most remarkable of these is the White Chandelier Lily, so called from having six narrow petals 4 inches long, pendant from beneath, and six stamens an inch shorter, growing out of the margin of a delicate funnel-shaped corolla.

The Acacia mimosa, said to be a native of the Nile, is a beautiful but fragile-looking tree, from 15 to 20 feet high, with small yellow flowers peeping out from among its branches of fine sensitive leaves, and giving forth a most delicious fragrance.

In passing through the forests we are continually struck by the number and variety of luxuriant vines, so closely interwoven with the branches of tall trees as to form a complete canopy. Most of them are covered with small white flowers, apparently almost too delicate to touch.

Many of the flower-bearing shrubs of temperate climes when transplanted here attain to the height of trees. Some years since a member of our mission brought across the Atlantic a small cutting of the Oleander, from which has sprung a number of stately trees. Some in the garden at Cavalla have already grown full 20 feet high, and are almost constantly covered with double pink flowers, which for richness and beauty surpass anything we have ever seen. A lovely sight it is to see these magnificent trees circled by birds of brilliant plumage.

Enough has been said to convince our readers that flowers, so appropriately styled "the smiles of God," have not been withheld from this land of moral darkness. We earnestly pray that the day may come when these beautiful gifts of our Heavenly Father may be appreciated by a redeemed and enlightened people, and that Africa spiritually as well as naturally, may "rejoice and blossom as the Rose."—(West African Record.)

### GRAPE-GROWING—INFLUENCE OF THE STOCK UPON SCION.

CIRCUMSTANCES alter cases, and a noteworthy illustration of the truth of the aphorism is the divided opinions of practical men as to the behaviour and merits of the Madresfield Court Grape. With some it is only a midseason variety, and the season, too, of briefest span; with others it has been known to hang well and in good condition even into the new year. In a dozen places it is convicted of its besetting fault of cracking; whilst in others it is voted to be perfectly free from that stain upon its character. A minute and careful inquiry into the particulars of soil, situation, and general treatment in each case would doubtless afford the "reason why" this difference of behaviour should manifest itself. Setting aside the consideration of its propensity to splitting, it is unquestionably one of the most desirable Grapes in cultivation when well grown. For size of berry, bloom, and appearance, combined with delicious flavour, a combination of Frontignan and Muscat, it has in our opinion few equals, scarcely a superior. Well, so much for its fruiting properties and fruit value: what is more immediately in hand is something more novel—namely, its

behaviour as a stock for another variety, an interesting instance of which was recently brought under our notice. It is scarcely necessary to tell our readers that Grape-growing at the Viceroyal Gardens is *Al*, or that our valued friend Mr. Smith is a master in this department of his profession. Well, even in that establishment, and in Mr. Smith's hands, this variety played false, would rend its beautiful coat, and thereby be unrepresentable at Court. As a consequence, though holding it in the highest estimation for its other good qualities, Mr. Smith resolved to discard it. Instead, however, of uprooting it altogether from the viney, he elected to head it down and inarch it with that grand-looking late variety, *Gros Colman*.

This operation was performed in the spring of last year, the result being a close union and stout well-ripened rod. This year the rod was shortened-back in the usual way, was started, and showed fairly for fruit. The embryo bunches were, however, removed, with the exception of one or so. Thus far all went on well, and now we come to the curious and interesting but by no means satisfactory part of the story—namely, the little-looked-for and less-desired manifestation in the graft of the evil propensity with which the stock variety is so generally charged. In a word, the bunch or bunches of *Gros Colman* had almost every berry cracked in the way as is the wont of the *Madresfield Court*. Here, then, is another curious—a by no means uninteresting, and, as far as we know, unrecorded—instance of the influence of stock upon scion. It is to be hoped Mr. Smith will give the worked Vine a year or two's trial, as it would just now be premature to come to a conclusion as to the demerits of the stock or to theorise as one might otherwise feel inclined to with regard to the explanation of the phenomenon in the present instance. We have never known or heard before of *Gros Colman* showing any tendency to skin-bursting. The thick, tough, and closely adhering cuticle of its large berries is not the one likely to give way, unless under some most exceptional circumstances. Have any of our Grape-growing readers experience or knowledge of showing this disposition? if so, we should be glad to hear it from them to that effect.—(*Irish Farmers' Gazette*.)

### STANDARD CURRANTS.

Not a little surprising is it that the standard form of growing Red Currants is not more widely adopted. The plan is a very old and a very good one. The Americans, it appears, are adopting it in growing Gooseberries, and there is no reason why success should not follow. The system of grafting, however, which is adopted on the Continent and in America is not necessary in growing standard Currants in England. Given vigorous stocks time is no doubt saved by grafting, but really the growing of cuttings into miniature trees is by no means a slow process.

Standard Red Currants are both ornamental and profitable, and the fruit on them is never attacked by birds so persistently as is fruit growing on bushes. I have grown standards for a number of years, and have found them of the greatest value. They take up but little room, are exceedingly fruitful, and unquestionably add to the attractiveness of the garden. The fruit on standards generally ripens before that on bushes, and it also keeps longer. If it is desired to preserve the fruit as long as possible it is easy to place round each separate head a guard of netting. This, however, is not necessary until the fruit from the bushes has been gathered, for the birds will not attack the exposed standard trees so long as any hidden fruit remains on the bushes which they can eat in comparative peace and quietness.

I commenced the growing of standard Currant trees on the score of economy and to save garden ground. My kitchen-garden space was limited, and the demand for Currants could not be met. I could not afford to devote another quarter of the garden to bush fruit, as scarcity in another form—the vegetable supply—would have followed. I therefore raised standards and planted some at intervals amongst the bushes, planting a standard between every third and fourth bush in every third row. The heads of these were formed well above the bushes, and, as I anticipated, the bushes produced as freely as ever, and a large supply in addition was given by the standards above them.

I also planted standards on the wall borders near to the edge next the walks. The trees were planted 18 inches from the walk and 15 feet from tree to tree. The stems were 3½ feet high, and the heads were formed from 2 to 3 feet in diameter. It was surprising the quantity of fine fruit that was

produced by these standards, and with no appreciable loss of ground. True, a root or two of early Potatoes were sacrificed in one part of the border and a few Lettuces in another, but these trifling losses were not felt, while the crops of Currants were a substantial gain. The miniature trees also added much to the ornamentation of the garden, and were generally admired for their appearance.

The trees I raised from cuttings. In the ordinary manner of raising trees from cuttings short-jointed medium-sized shoots are selected, cutting out the lower eyes and shortening the tops of the cuttings to the required height, leaving three or four buds on the top of each. In raising standards I found another plan, quicker and better. I selected the most robust shoots, carefully removing all the base buds, but not shortening the cuttings, leaving the terminal bud of each untouched. These cuttings were often 3 feet long to begin with, and when carefully planted in a north border they invariably rooted and did well. They were put-in in the autumn, and in the following summer made little growth, but in the season following they grew more than the required height, and were shortened accordingly at the winter's pruning and the heads formed.

I found, however, that a season was gained by grafting roots on to the cuttings. A piece of bushy fibrous root was dug up and its thick end cut into the shape of a wedge; this was inserted into an upward slit made near the lower end of the cutting and secured with a piece of matting. When this was neatly and quickly done, and the cutting with its new root planted without any delay, thus avoiding drying, I rarely knew a failure to occur, and the cuttings so grafted grew to the required height the first season.

Standard Currants, of course, require stakes to support them. It is important that these be sound and firm, and the ligatures must also be strong. The stakes must be placed close up to the heads, or during a rough wind the head of the tree may be broken off near the topmost ligature.

Especially to those having small gardens, and who desire them to be as profitable as possible and also attractive, I recommend that they grow Currants as standards along the sides of the walks. These trees will yield a valuable supply of fruit without taking up much ground, and they will also impart a pleasing appearance to the garden.—A NORTHERN GARDENER.

### ON GRAFT HYBRIDS.

BY THOMAS MEEHAN, GERMANTOWN, PHILADA.

[Read before the American Association for the Advancement of Science, at Buffalo, August, 1876.]

Of late years an impression has prevailed that hybrids may be obtained by grafting as well as by seeds. Sachs makes no mention of this in his text-book, but it has had a place in the literature of horticulture for over a hundred years. Bradley says that a variegated Jasmine grafted on a common green stock infused the variegation throughout the whole plant; and there is an idea among some horticulturists that an admixture in Apples can be obtained by uniting two halves of different buds and grafting them together. Thousands of people have laughed at these notions. No one has tried them. But only a few years ago it was found that Bradley was right; and we have in cultivation new variegated forms of *Abutilon*, as well as some other things originated by the graft process. During the past few years it has been asserted that new varieties of Potatoes have originated in this way: A tuber is taken and all the eyes cut out. A wedge with an eye of another kind is then inserted into the eyeless mass and planted. The results are said to be true hybrids. Many of our best physiologists doubt this. I have not seen these cases; but I must say the evidence offered is much stronger than much of that on which some popular theories have been built.

I tried the split-and-grafting process, not believing it would result in a hybridity. I merely wished to test the popular notion. I am pleased to be able to say now that it is correct. New varieties can be obtained in that way. I took the Rhode Island Greening and the Red Astrachan—two very distinct varieties of Apples in every respect. The grafts with a single bud were split as near through the centre as possible, and a piece of each kind fitted together so as to appear one complete scion. Twelve of these were grafted; three grew; two of these have fruited; neither are Rhode Island Greening, and the two are unlike each other; one of these has a flower like the Rhode Island Greening, and the flower of the Red Astrachan is rosy and in many ways distinct from the large white one of the

Rhode Island Greening; but the fruit is, in many respects, similar to that of the Red Astrachan. The second variety has the flower similar to that of the Rhode Island Greening, and the fruit somewhat the colour of the Red Astrachan, ripening about the same time, but is but half the size, very much flattened, and with a slender stem near 2 inches long, and as much like that of a Siberian Crab as can be. There is no doubt but two varieties, distinct from their parents and distinct from each other, have resulted from this graft process. Some may suppose that the union of a Red Astrachan and a Rhode Island Greening Apple should result in producing an exact intermediate, and that the union of buds in several graft cases should each produce identically the same, and therefore the two distinct varieties from the same process be a surprise. But no two children of the same parents are exactly the same; and this is the experience of plant-hybridists.

I do not know that there is any pomological value in the new varieties of Apples I have raised, but I am delighted with the scientific results, proving that hybrids by bud-grafting is more than a popular delusion.—(*American Gardener's Monthly*.)

### PRESENTATION TO DR. HOGG.

ON Tuesday evening, the 31st. ult., Dr. Hogg of the *Journal of Horticulture* was entertained to dinner by a number of gentlemen connected with the Gardeners' Royal Benevolent Institution, at Simpson's Hotel, in the Strand. The chair was occupied by Mr. John Lee of Hammersmith, and the vice-chair by Mr. E. R. Cutler, the Secretary. Among the gentlemen present were Mr. Robert Wrench, Treasurer; Mr. G. F. Wilson, F.R.S., Vice-President; Messrs. Herbert Adams, William Paul, E. J. Beale, B. S. Williams, Alex. Dickson, J. Cutbush, C. Turner, N. Sherwood, S. Woolley, G. Brush, Henry Cutler, James Gray, James Webber, &c. After the usual loyal toasts the Chairman proposed the health of Dr. Hogg, whom he said he had known for forty years. In a speech, expressive of great kindness and highly complimentary to Dr. Hogg for the services he had rendered to horticulture during a long period of years, he presented him with the following address, beautifully illuminated on vellum, and enclosed in a handsomely gilt frame:—

"At a meeting of the Committee of the Gardeners' Royal Benevolent Institution, held 2nd October, 1876, it was resolved unanimously that this Meeting desires to convey to Robert Hogg, Esq., LL.D., its best thanks for his kindness in presiding at the Thirty-third Anniversary Festival, held 30th June, 1876, for his great exertions in promoting the interests of the charity, and for his liberality and that of his immediate friends upon the occasion."

The evening was enlivened by some charming songs, exquisitely sung by Madame Marie Belval and Miss Brooks, accompanied on the piano by Mrs. Cutler.

### NOTES AND GLEANINGS.

WE learn through the same source which we quoted last week that Mr. Gilbert of Burghley has notified his intention of exhibiting a collection of DOUBLE PRIMULAS at the meeting at South Kensington on the 8th inst. The great value of this section of Primulas for winter decoration and the usefulness of the flowers for bouquets, &c., cannot be over-estimated, and Mr. Gilbert will do good service if he gives an impetus to their further cultivation by the means which he has proposed. An interesting collection of Grapes is expected also to be staged at the same meeting, with other products of special merit.

THE next dinner of the HORTICULTURAL CLUB is announced to take place on Wednesday, November 8th, and anyone joining the Club now will be entitled to the privileges of membership to the end of next year.

THE Bristol authorities have seized a large quantity of CURRANTS, value about £7000, which had been brought into port, and which had, it is alleged, become tainted with lead ore, part of the ship's cargo consisting of that substance.

THE great usefulness of DAHLIAS as garden decorative plants has been particularly exemplified during the mild autumn weather. The large round beds in the grounds of the Crystal Palace have for the last two months been extremely gay with these flowers, and have attracted fully as much notice from visitors as did the carpet and other bedding plants in summer. Latterly the Dahlias have quite overpowered the "fancy" beds by the bold character of the former, and the

purity, richness, and profusion of their blooms. The varieties employed in these beds are dwarf-growing early-flowering sorts of distinct colours, and no one who has seen the effect which has been produced can dispute their value for autumn effect. They prolong the beauty of gardens for six weeks, and are easily preserved and cultivated. They are certainly worthy of being largely grown in gardens generally, for no plants can equal them throughout the month of October. The Dahlias in the beds referred to have been flowering since August, and Mr. Thompson has displayed excellent judgment in planting them so effectively. The varieties we noticed were Alba floribunda nana, Rising Sun, Titian, and Zelinda.

A SPECIAL meeting of the members of the Woolhope Naturalists' Field Club was held at the Free Library, Hereford, on the 25th ult., to consider the question of publishing a "HEREFORDSHIRE POMONA," in annual parts, in continuation of "Knight's Pomona Herefordiensis." The chair was taken by Dr. Chapman of Burghill, the President of the Club for the current year. After an address by Dr. Bull, the following resolution was unanimously adopted:—"That a pomological Committee, consisting of members of the Woolhope Club, in conjunction with the growers of fruit, be formed to investigate the varieties of Apples and Pears grown in the district; to inquire into their origin and history, to ascertain their value and uses, and to name such varieties as are not known elsewhere, and have a really distinct character, with a view to the publication of a 'Herefordshire Pomona,' and that Dr. Hogg, F.L.S., be requested to edit the work. That the 'Herefordshire Pomona' should be published in annual parts, quarto size, in continuation of Knight's 'Pomona Herefordiensis.' That the first part should be issued at the close of next year, 1877; and that it should consist of three or more coloured plates with descriptive letterpress, according to the amount of annual subscriptions received. That the expenditure of the Committee be kept entirely distinct from the ordinary funds of the Woolhope Club, and that a separate subscription list be opened for defraying the expenses of publication. That the price of the parts separately be 10s. 6d. each, to annual subscribers 7s. 6d., and to annual subscribers who are members of the Club 5s. each part." Substantial subscriptions towards the carrying out this laudable object have been promised, an active Secretary in the person of Mr. Reginald Swinburne has been secured, and a Committee composed of the following gentlemen has been appointed:—Mr. W. H. Apperley (Withington), Dr. Bull, Rev. C. H. Bulmer, Mr. H. C. Beddoe (Hereford), Mr. John Bosley (Lyde), Sir Herbert Croft, Bart., Mr. Thomas Cam, Mr. John Cranston (King's Acre), Dr. McCullough, Rev. James Davies, Mr. J. T. Owen Fowler, Mr. Hall (Garford), Mr. F. H. Herbert, Mr. William Hill (Eggleton), Mr. W. Jay (Lyde), Mr. George H. Piper, Mr. Pitt (Bosbury), Rev. J. C. Robinson, Mr. James Rankin, and Mr. W. A. Swinburne. Under such auspices this important undertaking can hardly fail to meet with success.

IN another column is the record of a visit to a FRENCH VINEYARD. The visitor further refers to another vineyard, that of Baron Sarget at St. Julien. This formerly belonged to M. Gruaud, who built himself a tower from whence he could obtain a bird's-eye view of his Vines. From this tower he hoisted signals by which the story of the wine year might be known at all the ports of the world. If the captains of the trading vessels as they passed along saw a French flag hoisted on the Gruaud estate, they knew that the wine was good but light in quality; if the Dutch flag was floated the wine was known to be light, but of rather a superior quality; but when the English Union Jack was seen proudly waving there was great rejoicing, for it was a token that the Gruaud wine had plenty of body, and that it was a first-rate year. That was prior to the days of the electric telegraph.

IN the report of the ARCTIC EXPEDITION is noticed the most severe cold which has ever been registered, the "temperature being 59° below zero for a fortnight. The extreme lowest temperature on any day was 104° below freezing point." Something like a frost. Some Wheat sent out in the "Polaris" four years ago, in order to ascertain whether it would deteriorate when exposed to extreme cold, has been grown successfully under a glass shade by Dr. Belgrave Ninnis.

REFERRING to the AWARDS AT THE CENTENNIAL EXHIBITION, the *Philadelphia Press* states that "the excellent assortment of galvanised wire netting exhibited by Messrs. J. B. Brown & Co. of London, England, has obtained the sole international prize medal. Messrs. Brown & Co.'s collection of

English wire netting is, we believe, the most remarkable that has ever been shown in this country. It has been produced by improved machinery, which has not as yet been introduced into the United States." Awards have also been made to Messrs. Perks of Hitchin for oil of lavender; to Messrs. Veitch and Sons for trees, shrubs, and other plants; to Mr. R. Warner for two books ("Orchidaceous Plants"); to Mr. A. Waterer, Woking, for trees and shrubs; and to Mr. B. S. Williams for hothouse plants and Ferns.

— THE DAHLIAS in the neighbourhood of St. Albans were cut down by frost on the morning of the 25th of October.

— ON the 29th of October the Lord Mayor entertained the chief members of the FRUITERERS' COMPANY at the Mansion House. They had presented as usual the dessert, and the Lord Mayor complimented them on their varied collection of fruits. There was not very much, of course, in the fruit except its beauty, but there was a great deal in the kindly feeling which prompted the Fruiterers' Company to make that annual offering to the Lord Mayor of the day. As the custom had endured for ages, so it was likely to continue for generations yet to come, for there was no reason to anticipate any outbreak of hostilities between the Fruiterers' Company and the Corporation which would be likely to interfere with the annual offering. He regarded the Fruiterers as among the most pacific of men, their love for the cultivation of fruit and flowers tending to promote all the better feelings of human nature. He would ask the guests, therefore, to drink "The Health of the Fruiterers' Company," for by so doing they would only be giving them their desert. Mr. Stroud, the Master of the Company, acknowledged the compliment, and thanked the Lord Mayor for his hospitality on the occasion, which was always, he said, a magnificent return for their simple annual offering. He traced the custom which was being observed that evening through a long series of centuries, if not, he said, to the time when "Adam delved and Eve span."

— We read in the *Independence Belge* the following—"In a garden at Billancourt, the property of M. Carlin, locksmith, may be seen at the present moment an Apple tree loaded with fruit. There is nothing extraordinary in this, but the stock of the tree is Cherry, on which has been grafted the Apple, a species of Golden Pippin. The fruit precisely resembles Cherries—the same stem, the same size, the same form, and nearly the same colour, but its taste is that of an Apple, and it contains pips instead of stones. Specimens of this botanic phenomenon were yesterday submitted to our inspection. It must be a real curiosity, for it is generally thought impossible to graft a pip-bearing fruit on the stock of a tree bearing stone fruit."—[The only thing marvellous about this is that the narrator should have stated that the fruit produced by the graft was a Cherry instead of the Cherry Apple, and that he should not have satisfied himself as to the stock, which if he had examined he would have found to be an Apple. The Cherry Apple is the same as the Scarlet Siberian Crab.—Eds. J. or H.]

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

So far Scarlet Runners have afforded good pickings, but the nights have recently been too cold for the blossoms to set, and the supply of pods is exhausted. The late Mr. Robert Fish used to protect his Scarlet Runners and Dwarf Kidney Beans by running two rough straw ropes along the rows near the top. This would certainly be of advantage on a calm night in protecting them from frost, but in mild damp weather the straw ropes would do more harm than good, because they would prevent, to a certain extent, the free circulation of air, and would also shade the Beans from the sun. The ropes could be removed, however, in such weather, and be replaced when frost set in.

We have planted-out Cauliflower plants under hand-lights, one at each corner, and one or two in the centre. The centre plants will be removed in the spring and planted in the open ground. Another lot of plants have been placed in a cold frame. Such plants must not be coddled by keeping the lights on in fine weather, and if it is necessary to protect the plants from heavy rains the lights ought to be tilted sufficiently to allow of a free circulation of air. Late Cauliflowers that are now turning in may be protected by bending a leaf over the heart, for if the Cauliflower is exposed to frost it will be quite spoiled for use; but a leaf or two can be easily bent over, and no injury will then result from a few degrees of frost.

We have, after clearing off the stems of Asparagus, given the ground a good dressing of rich manure, and just put enough fine soil over it to prevent evaporation. The usual plan pursued with Asparagus beds is to dress them with manure, and then throw the soil from the alleys over the beds in the spring. We have been tolerably successful so far by planting in rows on a level surface and giving the plants a good dressing at this time, and there is always plenty of soil to cover over the manure. The plants were put out 18 inches apart in the rows and 2 feet 6 inches between the rows. This is quite close enough to give the plants justice. The first year or two after planting it was necessary to provide sticks to each plant to prevent the stalks snapping off close to the surface of the ground, as many will do if this precaution is not taken. If the stalks are broken early in the year before the buds are formed for next season, the crop on the injured plants will suffer considerably.

### MUSHROOM HOUSE.

This structure has not yet required to be artificially warmed, and the Mushrooms are of very good quality. Covent Garden Market is at present well supplied with excellent button Mushrooms and large succulent specimens for broiling at a cheap rate. Sometimes a bed will continue to bear a succession of Mushrooms for a long time, while another bed treated in the same manner will produce a good crop, which comes in with a rush and lasting but a very short time. To provide for such contingencies a bed should be ready two or three weeks after the previous one to ensure a supply. All Mushroom houses should be large enough to allow of a succession of beds. The most frequent cause of the beds failing to produce a crop after having been spawned properly, is overheating from manure that has not been sufficiently worked by turning. It is easy to blame the spawn or anything else, and to ignore the true cause. A thermometer ought always to be used for a test, as the hand is very uncertain. Always allow the temperature to fall to 85°, and there will be no danger unless the material of which the bed is composed has become too wet, which is another evil to be avoided. From 55° to 60° is a very good temperature for the house.

### VINERIES.

\* In many places it is quite necessary to place a considerable number of plants in the house where fruit is still hanging. Of course, in very large establishments, where there are houses for plants independent of the vineries, this is not done, nor should it be. When it is necessary to water the plants the morning is the best time, and a little artificial heat ought to be used to dry up superfluous moisture; in fact, all moisture is superfluous that falls on the paths or borders of the vinery at this season. If heat is turned on to heat the hot-water pipes to dry up moisture, it ought to be turned off again by one o'clock in the afternoon; no attempt ought to be made to dry up moisture towards night. When the weather is mild, and there is no dew-fall at nights, it is as well to leave the ventilators open a little. When there is much moisture in the air at night the house must be closed; the ventilators ought also to be closed during the prevalence of thick fogs. We have in previous numbers insisted on the necessity of removing all mouldy berries on their first being attacked.

Our early houses are all cleaned, the Vines washed, and borders surfaced, so that forcing may be begun at any time that may be deemed desirable. It is a very good plan, and has been followed here with the best results, to place some stable manure, or fresh manure mixed with fallen leaves of trees, in the house to ferment and throw off a moist heat. A good heap of fermenting material will warm the house a few degrees, also the ground to a certain depth; and the moist atmosphere caused by the ammoniacal vapour being thrown off is just what the Vines require to cause the buds to break freely so early in the season as this. From 45° to 50° is a sufficiently high temperature to start with. This may be increased 5° in the course of a few weeks, but we do not care to raise the temperature of the house higher than this until the buds show signs of starting into growth. These heaps of fermenting material are very useful for plunging pots of all sorts of early-flowering plants. We put some cocoa-nut fibre refuse over the manure in which to plunge the pots. The bed very frequently becomes hot enough to kill the roots if they are put too deep into the material. It is very necessary to guard against this. Roses, Lilacs, Deutzias, and other early-flowering shrubs do well thus plunged in the vinery, but they must not have more heat at the roots than 85° early in the season. We also put in a batch of Black Prince Strawberries in the early vinery.

### PEACH HOUSES.

There is not much to do in these structures at this season, and those who have much Peach-house accommodation will be able to store bedding plants, and also specimens intended for the greenhouse, until the Chrysanthemums have been cleared out of the latter structure after flowering is over. The Peach trees will take no harm if the plants are clean, but if they are infested with thrips, red spider, scale, or mealy bug, then it is a great mistake to put them in any fruit house.

It is now time to see that the "maiden" Peach and Nectarine trees are potted. Those who grow trees in pots will find that a few of the trees annually become unsightly owing to the under branches decaying. We never use pots larger than 15 inches inside diameter, and trees will do well for eight years; but after that age it is most desirable to throw them away and have younger trees to take their place.

#### PLANT STOVE AND ORCHID HOUSES.

It is now the resting period for all, or nearly all, hardwooded plants. They do not require a very large supply of water at this season, but it is well to keep the soil moderately moist, as neither stove nor greenhouse evergreen shrubs are benefited by the drying-off process. On my remarking the other day that a plant wanted water, a young man replied, "I should have thought if I had watered that plant it would have killed it." Now it does not follow that if a plant is watered before it is quite dry that any injury will result to the plant. Indeed it is a mistake to allow any hardwooded evergreen plant to become very dry at the roots. Injury will certainly result if the plants are persistently over-watered, owing to the compost becoming sour; but injury and sometimes even death to plants is caused by allowing them to become too dry, and often when plants are found in this state water is given in abundance to them, but too late, for the small hair-like fibres have been destroyed, and the roots are not able to absorb the moisture, and therefore the more water they receive the worse it is for them until fresh rootlets are formed. Hardwooded plants will do with less water now than they will in the early spring months. A dryish atmosphere is also the most suitable for them.

The earliest Poinsettias have set their flower buds, or more correctly the period has arrived when the floral bracts are in course of formation. They have now been placed in a higher temperature, and require a fair supply of weak manure water. We have cut-back the climbing plants trained to the roof to allow as much light as possible to the occupants of the stage underneath.

In the intermediate Orchid house *Lælia purpurata*, *Cattleya Warneri*, and others just now making their growth, should be placed at the warmest end of the house and receive rather more water than those that have ripened their growth. Most of the deciduous Dendrobiums have made their growth, and some of them have shed their leaves. Just enough water should be given to such to keep the pseudobulbs from shrinking. If the temperature is high and the roots are kept moist at this season some of them will start into premature growth. *Dendrobium nobile* should be rested in the greenhouse. In the cool house *Masdevallia Harryana* and *M. Veitchiana* are making their growth, also many species of *Odontoglossum*: these require a good supply of water at the roots; indeed they must not be dried-off at any time.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogues of Roses and Spring and Summer Flowering Perennial Plants.*

André Leroy, à Angers (Maine et Loire), France.—*Supplementary Catalogue of Fruit and Ornamental Trees, Roses, Bulbs, &c.*

George Cooling, Rose Nurseries, Batheaston, Bath.—*Catalogue of Roses and Fruit Trees.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JERSEY (St. Helier's) (Chrysanthemums). November 8th. Col. H. Howell, Hon. Sec.

SOUTH BERMONDSEY (Chrysanthemums). November 13th and 14th. Mr. D. Jewies, Rosedale Arms, Rosebury Street, Bermondsey, Sec.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

WIMBLEDON (Chrysanthemums). November 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Hon. Sec.

BRIXTON HILL (Chrysanthemums). November 17th and 18th. Mr. G. Goldsich, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

ISLE OF THANET, August 30th, 1877. Mr. C. D. Smith, Hon. Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

SEEDS (Palms).—We cannot recommend seedsmen. Any one of those who advertise in our columns could supply those you name.

BED OF SHRUBS FOR NORTH ASPECT (Paragon).—The shrubs are good,

and so is the arrangement, but we question whether its formality would not eventually prove offensive. Why not plant the entire bed with Rhododendrons? They will answer well in your sandy loam and thrive in the shade better almost than any other shrubs. The elegant evergreen foliage is always pleasant to behold, and a few choice sorts would afford an annual floral display of such beauty as can be had from no other plant or shrub in such a situation.

CULTURE OF *LILIUM ATRATUM* (John B. Boyd).—As none of your bulbs appear to be strong we must carefully shake off most of the old soil and forthwith plant the whole of them in pots in soil consisting of old turf sods and fibry peat and a small quantity of sand, letting the tops of the bulbs be about an inch below the surface. Plunge the pots in ashes in a cold frame till the spring, then when the stems are a few inches high and the roots touch the sides of the pots take the plants which you wish to establish permanently in open beds and borders and turn them out of the pots into carefully prepared stations 2 feet square, and of the same depth of a mixture of peat, loam, and leaf soil. Let the top of the bulb be 4 or 5 inches below the surface, and do not let a weakly growth during the first season induce you to disturb the bulb; only exercise a little patience, and you will be well repaid by the stout vigorous growth of the second year, pointing to yet more satisfactory subsequent results. The bulbs which you wish to retain in pots may be repotted in spring should they appear to require it, the condition of the growth and roots being a safe guide in this matter. After shifting replunge the pots in a bed of ashes in the open air, and keep them there till the flower buds are well developed, when the plants may be removed to the conservatory or other building in which you wish them to flower. Lilies grown in pots must have a liberal supply of liquid manure, say three times a week, and that for plants large or small to become fully developed and to yield fine flowers they must have pots in proportion to their size. One word more: if the summer prove very sultry, and there appears to be any risk of the foliage turning brown, remove the plants into shade for a time, but otherwise they may remain undisturbed till the flowering season.

TREES AND SHRUBS FOR AN ISLAND (An Old Subscriber).—Tall-growing trees are not very suitable for a small island. We have tried Birch and Holly, but neither have answered very well. Willows of all kinds and Alders answer perfectly, growing with great rapidity. We do not recommend these, but altogether prefer a mass of Rhododendrons, relieved by an occasional plant of Pampas Grass, and with a bold fringe of *Osmunda regalis* coming close down to the water. To impart variety to the fringe, both the purple *Loosestrife* (*Lythrum Salicaria*) and the yellow-flowering *Flag* (*Iris Pseud-acorus*) grow to a large size and give flowers abundantly when planted in the pond bottom with a foot of water above the roots.

FORCING VINES AND STRAWBERRIES (A Novice).—Prune the Vines immediately after most of the foliage has fallen; accelerate this by shaking the trellis to which the rods are trained. Remove loose bark and dress the canes with Fowler's insecticide. Thoroughly cleanse every part of the interior of theinery, and see that the roof is quite sound. To have ripe Grapes by the end of May close the house the third week in December and maintain a steady temperature of 50° for a fortnight, syringing the Vines daily with water of the same temperature as that of the house. Raise the temperature gradually, so as to bring it up to 60° at the end of another fortnight. Maintain this heat for a like period, and so proceed till you reach the maximum fire heat of 70°. Much rather would we press-on the Grapes after the period of stoning than at any previous stage, knowing as we do how mischievous is the effect of too high a temperature when the growth is very young. Strawberries started with the Vines will give ripe fruit in March.

KIDNEY BEANS FOR CHRISTMAS (Idem).—Osborn's New Forcing is the best sort of Kidney Bean for pot culture. It is a capital cropper, and so dwarf and compact in its growth as to require no stakes. Sow the seed immediately and keep the temperature at 60°. Do not lose a day now. Our second batch of pot plants sown the third week in September usually affords good pods till Christmas.

TRAINING PEACH TREES (R. F. B.).—You may train the trees downwards from the top, but the wires ought to be fixed not less than 10 inches from the glass. It is too late to shift Camellias into other pots. You may pot them before starting into growth next year.

WINTERING BEDDING PLANTS (W. T. D.).—The plants of *Ageratum*, *Lobelia*, *Nierembergia*, *Campanula gracilis*, and *Senecio elegans* should now be taken up and potted in fibrous loam with a little leaf soil, reducing the plants to a convenient size, removing the old flowering parts and retaining the young growths at their base, and taking up the plants with moderate-sized balls. They should be kept rather dry, having no more water than to maintain the foliage fresh, especially as your house is cool, but we presume frost is excluded. Many growers raise *Ageratums*, *Lobelias*, and double *Groundsel* from seed, thus dispensing with the trouble of wintering old plants, and economising space.

VIOLA ODORATA PENDULA (Idem).—It has been advertised in our columns under the name of "New York." We may say that it is a very desirable sweet-scented double-flowered kind.

CONSTRUCTING FORCING PIT (A. Taylor).—We think you have given the house too little height in the centre. We should have it 6 to 12 inches higher, or 7 feet 6 inches to 8 feet, and the side walls will need to be 3 feet high; but you may sink the pathway, so as to give the head-room required, as you would find a shelf over the pathway very useful for small plants. The wooden ventilators are no doubt introduced for economy. Lights would be better, and as you have no side ventilation the width you name is not sufficient. The width of the light should not be less than 18 inches, and this to open the whole length of the house. Wooden shutters obstruct light, and in winter you will need all the light possible. We should have a stage or bed for the plants, with its surface about 9 inches lower than the side walls. The ends would be best of glass above the height of the brickwork of the side walls. Two rows of 4-inch pipes will be required all around the house; or if you must omit the ends on account of doorways, have three rows of pipes along each side, it being true economy to have plenty of piping. To heat a similar house to a greenhouse temperature a 4-inch pipe all around the house will answer admirably, or if the ends are omitted have an additional pipe along one side.

SELECTED VINES (J. F.).—Three Vines that may be grown well in the vinery with the Black Hamburgh are Madresfield Court, Buckland Sweet-water, and Dr. Hogg; the latter has a rich Muscat flavour.

MAKING AN OSTER BED (F.).—Your ground being wet is all the better for the purpose, but water must be prevented standing on the surface. The Willows would grow were you to have open drains cut 12 to 15 inches deep at

about 21 feet apart, sufficient only to rid the surface of water; and if you do not object to the expense the ground would be better trenched, though the cuttings or plants would no doubt grow without preparation, yet the grass and other weeds would be better turned under. Instead of cuttings we could plant what are known as one-year cuttings, in rows 3 feet apart and 13 inches apart in the rows. The cuttings, if you put them in, should be a foot in length, three-quarters of their length being inserted in the soil. There is a great variety of Osiers—namely, Green or Common, Dutch or Red, Yellow, Purple Basket, and Red Basket. The first and last are probably most in demand.

**MANAGEMENT OF LATE VINES** (*A Constant Reader*).—In the first place you must see that the roof of your house is made watertight. If there is much drip it will be impossible to keep Grapes late. You will constantly see instructions as to the management of the house in "Doings of Last Week." We have never grafted Lady Downe's on Black Prince, but you might try and let us know how you succeed. You might also search Lady Downe's on two of the Black Hamburgs. The best time to inarch would be in early summer, when the young wood is becoming hard, but before it changes to a brown tint. Lady Downe's is the best late Grape. Alicante and Gros Colman are also useful. Trebbiano and White Tokay are the best late white Grapes.

**GREENHOUSE PLANTS FOR EXHIBITION IN AUTUMN** (*A Subscriber*).—*Flowering*: *Bouvardia longiflora* and *B. Vreelandii*, *Crocea saligna*, *Erica aristata*, *E. Marnockiana*, *E. Massoni major*, *E. Turnbullii*, *Lapageria rosea* and *L. alba*, *Statice Holfordii*, *S. profusa*, and *Kaloesanthus coccinea*. *Foliage Plants*: *Beaucarnea recurvata*, *Chamaecrops humilis*, *Cycas revoluta*, *Dasylium gracile*, *Cordylina indivisa*, *Lomatia elegantissima*, *Macrozamia Fraserii*, *Phormium Colensoi variegatum*, *Phormium tenax variegatum*, *Sarracenia darwinii*, *Yucca quadricolor*, and *Y. aloifolia variegata*. Some of the Australian *Terns* and *Zamias* also are handsome plants for exhibition purposes, and would be admitted in a class for foliage plants.

**DISTORTED SCARLET RUNNER STEM** (*J. Wallis*).—Many plants, especially *Asparagus*, are liable to the same distortion. It is termed fasciated, but the cause is not determined.

**WALNUTS** (*S. White*).—They are good nuts, but not superior to many others, nor so fine as some. If you sowed them they would not produce trees bearing similar nuts, nor bear at all for many years.

**CLIMBERS FOR CONSERVATORY** (*J. B., South Hackney*).—Your question is difficult to answer without knowing the size and position of your trellis, and whether it is shaded or otherwise. As a conservatory climber few plants give greater satisfaction than a well-grown *Maréchal Niel* Rose. *Lapageria rosea* and *L. alba* are amongst the finest of wall plants. *Mandevilla suaveolens* is also suitable. As rapid growers, *Cobaea scandens variegata* and *Tasmania Van Volxemii* are effective. *Ficus repens* is close and dense, and very useful for cutting from as *Heliotropes* and *Plumbago capensis*. Cuttings from the hoofs of horses may be advantageously incorporated with the soil of your vine border.

**POLLIN** (*J. H. E.*).—Pollens are too much alike for us to detect what flower has yielded your specimen.

**KEEPING WALNUTS** (*A. M. G.*).—To keep them fresh and dry there is no better method than storing them in large stoneware jars in layers, alternating with layers of sand. The jars to be placed in a cool cellar.

**GRUBS** (*A. H.*).—No grub remains always a grub, it becomes a chrysalis, and then a winged insect, the female of which lays eggs that produce the grubs. Those at the roots of your Fancies and Cabbage plants are probably the larvae of a saw-fly or moth.

**CATERPILLAR IN APPLE BRANCH** (*W. Nott*).—It is the larva of the wood leopards moth, *Zeuzera asculi*. It is common.

**NAMES OF FRUITS** (*J. Clow*).—Golden Winter Pearmain. (*Connaught Subscriber*).—2, Scarlet Nonpareil. Pears: 1, Madame Treve; 2, Jersey Gratioli. Plum: Coe's Late Red. Pear: Sussette de Bayre. We do not know the rest, and cannot name so many for one applicant. (*Rollo*).—1, Claygate Pearmain; 2, Delaware; 3, Norfolk Beaufin; 4, London Pippin.

**NAMES OF PLANTS** (*Iris 2*).—We cannot name plants from leaves only. (*H. A. F.*).—*Maurandia Barclayana*. (*Mrs. Frank*).—Parsley-piert is the Field Lady's Mantle, *Alchemilla arvensis*. It is portrayed and fully noticed in our "Wild Flowers." (*T. P.*).—A dark and good variety of *Ceanothus azureus*. Cuttings of the young shoots strike readily in sandy soil, placing the pots in a close frame. The plants should be grown in pots until they attain a good size, and then be planted at the front of a south wall. They need the shelter of a mat in very severe weather. (*Elsie*).—*Gymnogramma ochracea*; *Cassebeera triphylla*. (*Wm.*).—*Aspidium coriaceum*. (*Bathgalensis*).—1, *Scelopendrium vulgare bifidum*; 2, *Polypodium cambricum*; 3, *Pteris cretica albo-lineata*; 4, *Aspidium angulare*. (*J. M.*).—*Iris foetidissima*. (*Quevego*).—1, *Lastrea dilatata*; 2, *Polystichum angulare*; 3, *Asplenium*, sp.; 4, *A. marinum*; 4, *Blechnum orientale*; 5, *Doodia media*. (*J. W.*).—A species of *Thibaudia*. (*Constant Reader*).—*Maxillaria picta*. (*Iris*).—1, *Buddleia globosa*; 2, *Thuja occidentalis*; 3, *Muhlenbeckia* sp. ?; 4, *Solanum* sp. Specimens poor.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### POULTRY SALES.

THERE has been a great depression in the sales of prize poultry of late. Everyone nearly has remarked it, and over and over again we have heard the subject mentioned at the shows which we have attended. To keep up a large yard of exhibition fowls, or even to breed and bring up to the exhibition standard only a few birds, requires a very considerable outlay. All fanciers consequently, whether they be only working men who keep a few birds for their hobby, or whether they are the owners of vast estates who keep their exhibition poultry because they like to be great in everything—whatever they are, all like to have the expenses of their poultry recouped. This used to be done, and though we never could believe the wonderful sums were really made which we heard about, still without doubt the sales of many surplus birds prevented actual loss, and often put money into the pockets of the breeders. Those times, we learn,

seem to be passing away, for there seems to be a complete glut of prize poultry in England at the present time. Someone said to us at Oxford that supposing the "new disease" carried off some hundreds of birds, it would be all the better eventually, for the supply had very much exceeded the demand. We do not know if this is so with all breeds, but we fancy not; Dorkings especially we believe will always command a ready sale. There seems some hereditary fame about the egg-producing and sitting properties of this breed, and, in the castle and the cottage, all who know a cock from a hen stand up for the English Dorking. Great fancy prices may not often be obtained for this variety, but there seems to be a ready and continuous demand for specimens not up to exhibition form for farmyard stock which no other breed enjoys so much.

The question then naturally arises, What is the cause of this depression in the sales of fancy stock? We think there are several. We put aside entirely the reason which we have heard lately suggested so frequently, that from the dulness of trade and business there is not the same proportion of money to be expended upon this hobby; we lay that aside, because with very many it is not the case, and because we noticed it coming on when trade was in its most flourishing condition.

Then we come to another cause, and that we are assured by very many experienced breeders of many years' standing is the real source of all the mischief; we allude to the selling classes. At exhibition after exhibition we are begged by our greatest authorities to try and stop the sale classes. We assure them we can never do it, for we do not believe it is to be done; but at Oxford last week we were once more formally begged to write against this system. We do it without a shadow of hope of effecting much good, for the sale classes pay well; and where the classes pay it seems ridiculous to imagine that the show authorities, with whom alone the matter lies, will themselves try to quash the most lucrative portion of their schedule. Still, we believe with those who have set their backs against the selling-class system, that they often do much harm; for fanciers frequently wait to buy through some sale class of this description, where they imagine they can procure something good and cheap, instead of applying to someone who will probably charge them a few shillings more but send them a bird of superior quality. With birds purchased out of these classes, however, there is much disappointment, for even if a specimen is entered in the name of some well-known breeder, who is to know if he really bred it or not? and often a bird so purchased brings in a bad cross and spoils the whole year's breeding, and sometimes makes a new beginner throw up the whole thing in disgust. Mr. T. C. Burnell, in "The Exhibition Dorking," advises no one to procure stock for breeding out of sale classes. Breeders cannot afford to do it. They cannot put two or three good birds in a class for 40s., as sometimes has to be done; the quality so found therefore must be poor, though to the uninitiated it may seem a tempting bargain. Perhaps the selling classes at the very important exhibitions do not do so much harm as those at the smaller shows, for at the Palace, for instance, the chance of a good prize, and the knowledge that the birds will be put up to auction, tends to procure good specimens; but it is at the smaller shows where the mischief is done, and we ask committees who do not find their sale classes remunerative, as we conclude some must do, to try and make a beginning by no more inserting those classes in their schedules. We do not object to the £5 ss. classes as at the Crystal Palace, as for that sum a good pair of birds should be obtained. When we think that at the late Crystal Palace Show close on five hundred pens of birds were offered at £2 a pen through these mediums, all will readily see to what a pitch the sale-class system has now arrived at. As we cannot expect the managing powers themselves to give up these most profitable classes, it lies with breeders and exhibitors to see whether they, by patronising less these cheap ways of parting with their birds, cannot once more try to bring the value of good specimens up to the old rate. It is not so much that we want to see unnatural prices given again for fancy fowls, but what we think is, that new beginners by buying really rubbish get disheartened, and, instead of helping to cement closer together the members of an innocent amusement, in their disgust do harm to the fancy by running down the birds purchased and the characters of the vendors.

Lastly, we come to one more reason which we think a very powerful one. It is that so many hundreds of imperfect birds are annually allowed to live. They are not half slaughtered enough. The birds are allowed to live in the hope that they will some day out-grow their infirmities, and they never do, so perhaps they are sold at a small price, and go to form the nucleus of a fresh exhibitor's yard, and only bring terrible woe upon him. It is not the great exhibitors who refrain from killing. They know better. They have a reputation and a name at stake, and those it is who feel the depression in the sales of birds so much. They kill right and left birds with hocks, with wry tails, with crooked claws, with imperfect plumage, with crooked combs, with bad shape. Such birds are made into pies and pasties, and are never allowed to go abroad and injure a fair reputation;

and how can such afford to sell a bird at a few shillings? It cannot be done; and until the selling-class system is modified, and imperfect birds more readily slaughtered, we despair of seeing a return of the halcyon days when one's hobby not only was an amusement but allowed both ends to meet.—W.

### OXFORD POULTRY SHOW.

WITHOUT any doubt whatever the Show just over at Oxford has been one of the greatest successes ever experienced by any society. With an able Secretary, energetic Committee-men, and a good prize list, the Show has gradually worked its way on, and now in 1876 we consider that it most certainly ranks only second to the Crystal Palace Show. Could only space be found to allow of the sexes being divided and classes added for old birds, there is no knowing where this Show might end, for as it is two thousand pens are quite enough for the buildings. The quality was wonderfully good throughout, and in most cases we thought the judging quite up to a fair average. The birds were most carefully seen to; the soft food, green meat, and sods of turf for the Game cocks being all admirably arranged. No one was admitted till after the awards were made, and consequently all were in the same boat, whether present in the town or not. Mr. King superintended the birds in the Corn Exchange, and Mr. Salter the Pigeons and Bantams in the Town Hall, which latter building was tastefully decorated with flags and shields. We now pass to the awards.

**Dorkings.**—In Coloured, as a pair, we think our choice was for the second-prize pen, but the cock had a double toe nail, which may have gone against him, or else he was a grandly-grown cockerel. The cup cockerel was large and good in feet, but the hen was small. Third were good birds and fully matured; while the fourth went to a capital pair good all round, and we liked them much. We were sorry to hear Mr. Burnell's pullet had died. In Silver-Greys the cockerel was a fine bird, beautiful in shape and colour, with a good pullet. Second also good, and we thought we liked the cockerel as well as the cup bird. Lady Dartmouth and Mr. Cresswell each sent a very good pullet. In Whites the Ipswich cockerel was first with a fresh pullet. He was very showy, and is, perhaps, the whitest Dorking we ever saw. Second and third were much larger, but not so pure in colour. Blue Dorkings appear to improve. The cup pair matched well. The breed seems to acquire size and the Dorking squareness of shape.

**Spanish.**—This was a small class and a poor one, though the cup pullet was a good bird. We liked Mr. Beldon's pair, and would have placed them before the third-prize pen.

**Cochins.**—These made four grand classes. Buffs especially were very good. The first and second Buffs were very even in quality, though some preferred the second-prize pen. Their colour was pure and even, and they had good feathering and abundant fluff. The third were very poor, and we far preferred some other pens. Excepting the first and second cockerels the pullets struck us as being better than their companions. In Partridges we liked the first cockerel; he was smart in shape and good in colour, and much reminds us of the bird we have seen Mr. Percival show. The second pullet was a pretty one, but we dislike the legs of the second cockerel. We saw him before in the same position at Ipswich. Blacks made a good display, and we noticed that all either had spindly-shaped hocks and legs, or enormous hocks. They seemed, too, so much wilder than other Cochins, and to dislike being handled. The first pair were very fluffy and good in colour. Second a fair pen, rather larger than the third, otherwise not so good in colour. Whites made a fine lot of a dozen pens. We did not admire either of the first or second cockerels, they were too creamy and tailless. The second pullet was a beauty. As a pair we liked Mrs. Tindal's, only we do not like the cockerel's comb. He is the cup Aylesbury and first Ipswich bird. We liked Lady Dartmouth's pen very much, and had the cockerel only more leg-feathering should have felt inclined to place them near the top of the tree.

**Brahmas.**—The first Dark pullet was good in pencilling, and the cockerel was large and massive, but had an imperfect wing. Second pullet also good. Third and fourth good pairs of birds of fair quality, but no bird in the class had the stamp which Mr. Lingwood showed in 1874 and 1875. We very much admired the pens of Messrs. Pritchard, Garner, and Birch. In Lights the first cockerel was a grand bird, but too high in tail, or else of wonderful symmetry and carriage. His pullet was of good colour and large, and only wants more distinct markings in her neck hackles. Second pullet good, and the third cockerel promises to make a grand bird. Mrs. Holmes sent a pretty but rather small pair, as too did Mr. J. Bloodworth.

**Game.**—These classes were first-rate. We liked the awards fairly. The condition and bloom of the £10 10s. champion was good, but we heard many Game fanciers object to the award. Mr. Matthew's and Mr. Dutton's cockerels all were much harder in feather. All highly commended birds were almost worthy of prizes, so good was the quality. The first Brown Red cockerel was very grand in colour and carriage, and had his comb on.

The same owner's undubbed Duckwing was also a splendid bird—grand in colour and fine in shape. The Brown Red pullets were well selected, and were a good lot. The second we especially admired. Undubbed cockerels were superior. A Brown Red won first. He was of lovely colour, and stylish in carriage. A Brown Red also won second, while a Black Red took third honours. We were glad to find the class so well filled, and thank the guarantor for his share in this good work.

**Hamburghs.**—We did not think them quite up to the standard of other years. Roup was observable in many pens, and many birds looked pale and jaded; but there was a wonderful improvement in the honesty of the combs. Many objected to the first Golden-pencils, but we did not think them so very bad, though certainly the third pullet was very neat in markings and head. In Silver-pencils we found no improvement, and are sorry to find the breed so little cultivated. The first pullet was pretty, and so was the second cockerel, while third went to a very good pen, which we thought hardly used. In Spangles the first cockerel was good in colour, but not at all neat in head, with a rich-coloured pullet. Second also very brilliant and well marked. Third, again, very handsome and in beautiful bloom; and we thought all the pens well placed. In Silver-spangles the cup pullet was a gem, and her mate worthy of her. Second fair in colour, and the cockerel good in tail. Third had good lustre, and the cock's carriage good. In Blacks the cup pen was gorgeous in colour; second also very smart, and good in shape. Mr. Sergeantson's pen was very good in colour and condition.

**French.**—Houdans mustered well, and the birds were mostly well grown and healthy. We liked Mr. Boissier's pen much the best. The cockerel had a splendid leaf comb. He is the Bath cup bird, but has now a bad claw; this, we conclude, threw the pair out, for the pullet was a beauty which accompanied him. The cup cock lacked crest, and was not quite our favourite colour. The fourth cockerel came next to Mr. Boissier's for head properties, but was rather small, while the third too seemed small by some of the others. In the next class good La Flèche came in between two pens of first-rate Crèves; the first pullet was very large and in good feather. We noticed a very ancient pair of La Flèche in a highly commended pen, and a pair of Crèves claimed for £10 10s.

**Polands.**—Of these there were two superb classes. We never saw such a class of Blacks before in a chicken show. The cup cockerel was lovely, and his mate simply gigantic in crest; but neither were very white, and were they only of pure colour we can well imagine their being the finest pair of the variety in existence. Many thought the pullet was a hen, but we do not think so, and we closely inspected her. Second went to the first Ipswich pen, now in new hands, they are good in crest and very white; while third went to a neat pair of younger chickens. Mr. Darby showed a good pullet; Lady Dartmouth sent a grand cockerel, which we personally preferred to the third-prize pen; and Mr. Norwood sent a lovely pair, but we are most sorry to say the cockerel hit his head against the basket and nearly died from the effects; but the kind wife of the Secretary took it home and gave it hourly attendance throughout the night, and to this lady's exertions alone can the life of the bird be attributed. In the next class Mr. Adkins cleared the board. We, however, liked his second pen best, which have gone to a northern home for £20; and after them we liked Lady Dartmouth's or Mr. Unsworth's Golds; it was a grand class.

**Leghorns.**—Browns came well to the front, while Whites were in numbers far behind. The cup Browns were, as a pair of birds in one pen, the best pair we ever saw together. They were fair in ears and very good in all other points. Second and third pens also good. In Whites another cup went to Aylesbury for a neat and cleanly-shown pair of birds.

**Malays.**—The cup pen were large and fine in shape, and these points must have pulled them through, for other birds possessed much more quality in colour and feathering. The cockerels of Miss Brooke and Mr. Hinton seemed to be younger, and we think they will make splendid birds. It was one of the best classes we ever saw, and we were glad to see the faces of many Malay fanciers. Someone from Rugeley found a cheap bargain in Mr. Hinton's 40s. pen.

**Silbies.**—These made a very pretty lot, and they found hosts of lady admirers among the spectators. The cup pair were snowy white and good in combs. The pullet was the cup Ipswich bird, with a good cockerel. The second were good, but too heavily feathered and rather ugly about the hocks. The third pullet was huge in crest, but her mate was full of pin feathers, and we preferred, as they then were, Mr. Cresswell's pair. We heard a long price refused for the cup pen.

The Variety class comprised an immense medley of nineteen pens. The numbers might all have been put in a bag and the winners so drawn out. Black Minorcas won first, Andalusians second, and Sultans third, all good specimens; and many more as good had to put up with commendations.

**Bantams.**—The Game were wonderfully good. We liked the first Brown Reds and the cup Piles very much. We heard

many say the third Black Reds were the best pair of Bantams in the Show, but the light was poor, and the Judge had much difficulty in making his awards. Blacks were beautiful, pen after pen of great excellence; the cup pair fine in head and shape, and also were the second and third. Sebrights were poor. Shade of Sir John, come and stir fanciers up! The first went to Silvers, second to Golds, both of course Mr. Leno's. In the Variety class a pair of Pekins were first, the cock in good feather, but the hen the reverse; second neat White Rose-combs; and third very good Black-boots. They were a shade too large, but very lustrous and bright.

**Waterfowl.**—All these classes were good. Aylesburys and Rouens were of rare excellence. We heard that £20 had been refused by the owner for the second Rouen drake. He is a grand bird, and was, we believe, the cup bird at Malmesbury. In Blacks we liked the awards. It is amusing to see how the different birds get different places. Some liked Mr. Burn's the best, but we thought as a pair the cup pen were the right birds. Second were very good, and so were three or four more pens; but the quality was so good throughout that it made the judging a difficult work. The next class was simply exquisite, pen after pen of wonderful excellence, and nearly all conceivable varieties being present. Mandarins were first, and we much regret to say one died during the Show; Carolinas took second, shown in faultless feather; and third went to Bahamas. These have different coloured heads in the different sexes, which reminds us of the Ruff and the Reeve which we saw at Portsmouth. An extra prize or two might well have been given here.

A pretty collection of Pheasants finished this department, where Golds were first, Whites in bad feather second, and Swinhoe third. We were pleased to see the Show so well attended, and we hope the balance will be a good one on the right side. We see the dates for 1877 are published in the catalogue, so if others clash with this important Exhibition it will be their own fault.—W.

#### PIGEONS.

With possibly one exception there has never, we believe, been gathered together a finer collection of Pigeons than were in the Oxford Town Hall. The greatest care and attention were bestowed on them, and the building is so well suited to the purpose that no wonder exhibitors trusted the choicest of their studs. It was a charming sight on passing down far-stretching classes to see scarcely a single bad bird. But we must proceed to particulars.

**Carriers, Blue or Silver Cocks** (twelve entries).—First was a grand Blue all round, beak-wattle capital, and eye-wattle high and good. Second another Blue, fine in form but with wattle not fully developed. Third a Blue with a good box beak. Hens (ten entries).—The winners all Blue and good. Mr. Bentley showed a bird which in most respects was the flower of the class, but she was not in trim, and carried one wing loosely. Any other colour cocks (seventeen entries).—First, Mr. Baker's now famous winner. He certainly is a grand bird, but as Mr. Fulton says in his book, a perfect Carrier has scarcely been seen, and so this bird has his drawbacks—he looks a little short and has an overlapping beak. Second Mr. Baker's old Black; he was unfortunately too lame to stand up and do himself justice. Third another Black with good wattle, but showing too much space between the beak and eye-wattle. Hens (sixteen entries).—The winners were all Duns. We did not think much of the class as a whole. Blue or Silver, hatched in 1876 (nine entries).—The winners were all Blue. We feared there were several old birds in this class. Any other colour (thirty-two entries).—To this class the Judges appended a general commendation, "An extraordinary good class." The winners were all Black and seemed well placed. First was in all ways a wonderful young bird.

**Pouters, White Cocks** (seventeen entries).—The first combined immense length with slimness. Second had a fine crop, but looked to us a little thick in body. Hens (ten entries).—We liked all the winners, Mrs. Ladd's third-prize one perhaps best of the three. We also thought her unnoticed hen a beautiful bird for its great elegance of form. Any other colour Cocks (seventeen entries).—The first-prize bird in this class took the cup for the best Pouter. He is a Blue and very young. Great exception was taken to the award, but we must say we did not think it a bad one; he is a most symmetrical bird, very small in girth, and of exquisite colour. Second and third were Blacks. We should have reversed their order, for Mr. Pratt's is a grand bird. Hens (fifteen entries).—First a good Blue; second a Yellow very long in limb; third a Red. We much admired Mr. Baker's Black.

**Barbs** (fourteen entries).—We were glad to see Mr. Hedley again showing in this class, and, as of old, carrying first honours with a grand Black. Second a magnificent Yellow and small too, a hen we believe. Third a Red with somewhat unhealthy eye-wattle. Barbs of 1876 (nine entries).—Mr. Hedley first again with a very promising Red. Second a good Black, though far behind the first. Third another good Black.

**Tumblers, Almond.**—First and second capital birds, the former

the richest in colour. Hatched in 1876 (eleven entries).—It is very interesting to see this class before they have "broken." All three prizes went to one exhibitor; his three birds were, we thought, very even in merit. Short-faced, any other Variety.—First a Black Kite, second a Red, third an Agate. Balds or Beards, not Short-faced (thirteen entries).—First a capital Red Beard much smaller in head than one often sees Long-faced Tumblers; second a Black Bald; third a Silver Bald. Any other Variety (fifteen entries).—First a Yellow Mottle; second a Silver-muffed; third a Black Mottle.

**Dragoons** were the great feature of the Show, though we do object to such undue prominence being given to the breed, which had eighteen classes, while the beautiful old-fashioned Jacobin had but one! *Sic transit gloria mundi!* Many of the less popular colours in Dragoons had miserably-filled classes. Blue Cocks (thirty-six entries).—The first cup went to No. 1 in this class, a very big bird with a good V-shaped head. Second and third both capital birds, even in colour. We prefer not to see wattle under the beak which the second had. 1310 (Shutler) was a good true Dragoon, defective alone in bar. 1305 (Leach) very highly commended, good, but inferior in colour to the last-mentioned bird. Silver Cocks, Black-bars (six entries).—Why not distinguish between this and the next class by calling them respectively "Blue Silvers" and "Brown Silvers?" The nomenclature would be much more correct. First a splendid bird, though his bars were not what we call black. Second also good with less wattle. Third heavy in wattle and Carrier-like. Silver Cocks, Brown-bars (nine entries).—Mr. Bishop's birds were here far ahead. First a very good bird; second heavier in wattle. Red or Yellow Cocks (eleven entries).—First a Yellow splendid in colour, "London Farcy;" second a very dark Red; third a Red, its style we much liked. White Cocks (seventeen entries).—First a beautiful bird, good in shape, of medium size, broad in skull, and with eye-wattles singularly perfect all round. Second not quite so good. Third like the first but coarser in head. Any other colour Cocks (ten entries).—First a fine Grizzle, London type; second and third Blue Chequers. Blue Hens (twenty entries).—First a magnificent bird all round, shown by a local exhibitor. Second the type of Dragoon we like. Third rather long in beak; she was so fine in head as to make up for her light rump. Silver Hens, Black-bars (twelve entries).—First and second in splendid condition. Silvers, Brown-bars (eight entries).—First rather heavy in wattle; second a good Dragoon; third good in head. Red or Yellow Hens (nine entries).—First a somewhat large Yellow, excellent in colour. Second another Yellow not quite so bright. Third a capital Red. White Hens (sixteen entries).—All three winners capital birds with little to choose between them. Any other colour Hens (five entries).—First-and-cup a fine Blue Chequer. Second and third Grizzles. Blue of 1876 (thirty-seven entries).—A wonderful class. The cup bird was at once bright and deep in colour. The young birds had six classes, the colours being classified as in the adult classes. Time failed us to look at every bird. We observed that the second-prize Yellow (Hon. W. Sugden) was claimed for fine guineas.

**Antwerps, Short-faced** (twenty-three entries).—First a good Red Chequer. Second a Silver Dun very rich in neck colour. Third a Red Chequer. 1522 (Bradley), highly commended, was, we heard, the Alexandra Palace winner of last year, now not in good condition. Long-faced and Homing Antwerps also had classes, and numbered close on one hundred entries.

**Runts** (fourteen entries).—A fine class. First a huge and well-known Blue. Second and third Silvers.

**Owls, English** (twenty-three entries).—Apparently the foreign and English varieties of Owls are getting much intermixed, for the English are becoming smaller, the foreign are larger. The winners in this class were all Blues, very even in quality. Foreign Owls (eleven entries).—First-and-cup a White, not very small. Second another White, smaller. Third a pretty little Blue.

**Nuns** (eighteen entries).—All the winners Black. The class was singularly good, if there had been no trimming.

**Turbits, Blue or Silver** (fifteen entries).—First a Silver generally good, but defective in gullet. Second a little Blue, rather dull in colour. Third brighter in colour. Any other Colour (twenty-five entries).—First a remarkable bird, its great merit head properties, its defect want of colour. Second a Black, capital in colour. Third an indifferent Yellow. Some well-known birds in this class were not noticed.

**Fantails** (twenty-two entries).—A fine class. Everyone seemed astonished at the first award. There were at least six better birds. Second and third very good. Several capital birds were highly commended.

**Jacobins** (seventeen entries).—A poor class as a whole. This comes of all colours being crowded into one class. First and second were good Reds, third a pretty white.

**Maggies** had two classes, numbering fifty between them. First and second (Blacks) were admirable birds. The cup went to a superb little Yellow.

**Variety** class (thirty-three entries) must have given the Judges

much trouble, and apparently puzzled them in the end, for the first award was most unsatisfactory; it went to a "Black Archangel," so called, in reality we believe a cross between an Archangel and some other breed. A pair of these birds were shown at Reading last year and won. A large exhibitor claimed them, but finding out his mistake was, we heard, glad to be quit of his bargain. Second a fine Black Trumpeter, new type; third a Spangled Pouter. Some lovely Archangels and one or two fair Austrian Pouters were in this class.

There were two Selling classes for single birds, value respectively under 60s. and under 30s.

The Judge's for Pigeons were Messrs. Esquilant and Jones, who were busied at their labours nearly twelve hours. The wonder is that the Show was so carefully and, on the whole, so satisfactorily judged.

**POULTRY.—DORKINGS.—Coloured**—1, H. Lingwood. 2, R. W. Beecher. 3, W. W. Rathbone. 4, O. E. Cresswell. 1 Local, J. C. Fraser. **Silver-Grays**—1 and 2, C. F. Herrieff. 3, Hon. Mrs. Howard. 4 and 1 Local, E. Woodford. 2 Local, J. Calcutt. **White**—1, R. A. Boissier. 2, Mrs. M. A. Hayne. 3, O. E. Cresswell. **Any other variety**—1, T. C. Burnell. 2, J. Isard. 3, J. H. Putney. 1 Local, J. Gee. 2 Local, R. Gunstone. **SPANISH**—1, J. Walker. 2, J. Aldridge. 3, J. Thresh. 1 and 2 Local, H. Johns. **COCHINS**—Cinnamon and Buff—1 and 2, W. A. Burnell. 3, Mrs. H. Shutt. 2 Local, J. Gee. *vhc*, Mrs. Hacldey, Capt. L. S. Robin, Mrs. A. Tindal, R. Tomlinson. **Partridge**—1 and 1 up, E. Tudman. 2, Mrs. A. Tindal. 3, R. P. Percival. **Black**—1 and Cup, H. J. Storey. 2, W. A. Burnell. 3, A. Darby. 1 Local, A. Kitchen. **Any other variety**—1 and Cup, J. H. Nicholls. 2, Rev. H. J. Borrow. 3, Mrs. A. Tindal. 2 Local, J. Craddock. *vhc*, Rev. R. S. S. Woodgate. **BRAHMAS**—Dark—1 and Cup, R. P. Percival. 2, Rev. T. C. Peake. 3, F. Bennett. 4, Rev. H. F. Hamilton. 1 Local, E. Ayre. **Light**—1, Rev. H. J. Borrow. 2, G. W. Peter. 3, P. Haines. 4, J. T. Hinks. 2 Local, T. Smith. **GAME**—Black-breasted Red. 1, C. F. Herrieff. 2, A. Beck. 3 and 3, S. Matthew. 1 Local, E. Woodford. 2 Local, F. P. Mowbray. 3, A. Darby. 1 Cup, P. L. Lyon. 2, W. J. Pope. 1 and 2 Local, R. J. Pratt. *vhc*, Hon. and Rev. A. Dutton. 3, Field, W. J. Pope. **Brown-breasted and other Reds**—Cockerel—1 and Cup, S. Matthew. 2, C. H. Wolff. 3, F. Ward. 1 Local, W. R. Pratt. 2 Local, J. Hill. **Pullet**—1 and Cup, T. Mason. 2, H. E. Martin. 3, Robinson & Braithwaite. 1 Local, J. Loader. 2 Local, I. Hawtin. **Any other variety**—Cockerel—Cup, S. Matthew. 2, J. A. Nather. 3, H. E. Martin. **Pullet**—Cup, S. Matthew. 2, T. P. Lyon. 3, D. W. J. Thomas. 1 Local, Miss A. Bunney. **Unadorned**—Cockerel—Cup, S. Matthew. 2, W. Watson. 3, Hon. and Rev. F. D. Brough. 2 Local, T. Smith. **HAMBURGERS**—Gold-pencilled—Cup, H. H. Thompson. 2, W. Tickner. 3, Duke of Sutherland. 1 Local, J. T. K. Castell. 2 Local, J. Calcutt. **Silver-pencilled**—Cup, Duke of Sutherland. 2, J. Rawnsley. 3, H. Beldon. **Gold-spangled**—Cup, G. & J. Duckworth. 2, T. Blakeman. 3, H. Beldon. 1 Local, J. Calcutt. **Silver-spangled**—1, Ashton & Booth. 2, H. Beldon. 3, G. C. Holt. 1 Local, J. Gee. 2 Local, J. Stoddart. **Black**—1, J. Pickup. 2, Stott & Booth. 3, H. Hoyle. 1 Local, Miss A. Bunney. 2 Local, E. Woodford. *vhc*, P. Hinde. **POLANDS**—Black with White Crests—1, Lecher. 2, E. Burr. 3, J. Feardley. *vhc*, Countess of Dartmouth. **Any other variety**—1, 2 and 3, G. C. Akins. **HOUDANS**—1, Mrs. Vallance. 2, A. Uden. 3, S. W. Thomas. 4, G. D. Harrison. 1 Local and *vhc*, R. Harvey. 2 Local, Rev. G. Day. *vhc*, W. Howard. **JENCHEN**—Any other variety—Cup and 1, W. F. Upsher. 2, H. Stephens. 3, E. Burrell. *vhc*, W. F. Upsher. 1 Blanchard. **MALAYS**—Cup and 2, T. Lecher. **Local**, Miss A. Bunney. *vhc*, J. E. Watson. **LEGHORNS**—Brown—Cup and 1 and 2 Local, A. Kitchen. 3, E. Chubb. 2 Local, J. Kirk. *vhc*, J. Nelson. **Any other variety**—1 and 2, R. Brownlie. 3, G. Hall. 1 Local, J. Kirk. **White**—Cup and 3, R. R. Fowler. 2, A. Ward. *vhc*, R. R. Fowler. 4, Ward. **SERIES**—White—Cup and 3, Rev. R. S. S. Woodgate. 2, Mrs. J. T. Holmes. 1 Local, S. Shuffrey. 2 Local, Rev. R. S. S. Woodgate. 1, J. B. Williams. 2, J. H. Fry. 3, E. Barnett. 1 Local, E. Ayre. 2 Local, J. Rogers. *vhc*, W. H. Coppleson. **BANTAMS**—Game, Black Red—1 and 2, G. Hall. 3, J. Nelson. 1 Local, J. C. Fraser. 2 Local, Master H. Cavell. *vhc*, W. F. Addie. **Game, Brown and other Reds**—1, F. L. Davis. 2, E. Walton. 3, G. E. Farrington. **Game, any other variety**—1 and 2, R. Brownlie. 3, G. Hall. 1 Local, J. Kirk. *vhc*, J. Nelson. **Steel**—Black—1, R. Ashton. 2, F. Beauland. 3, J. W. Earnshaw. 2 Local, E. Ayre. *vhc*, W. H. Shackleton. **Silver**—1 and 2, M. Leno. 1 Local, J. C. Fraser. *Any other variety*—1, H. B. Smith. 2, E. Walton. 3, Mrs. J. T. Holmes. *vhc*, Mrs. M. C. Davies. **DUCKS**—Aylesbury—1, J. Walker. 2, J. K. Fowler. 3, T. Sear. 1 and 2 Local, J. C. Fraser. *vhc*, J. Hedges. 3, J. Pearson. **Local**, Rev. E. Within. *vhc*, W. G. Chubb. 2, E. Berry. 3, P. Ogilvie. 2 Local, Rev. E. Within. *vhc*, H. H. Thompson. 1 and 2, S. Sainsbury. 3, S. Hurn. 2 Local, T. Taylor. *vhc*, J. Walker. **White**—1 and 2, Mrs. H. J. Bailey. *Any other variety*—1, Mrs. Arkwright. 2, M. Leno. 3, Rev. W. Serjeantson. 1 Local, W. R. Pratt. *vhc*, H. B. Smith. M. Leno. A. & W. H. Silvester. 1, Trickett, H. Yardley, J. Booth. *vhc*, R. Rootes. 3, Walker. **PHEASANTS**—1 and 3, W. C. Drummond. 2, M. Leno. *vhc*, W. B. Gibbins. **TURKEYS**—1, W. Wykes. 2, H. Gurnell. 3, E. Lysall. 1 Local and *vhc*, H. T. Sotham. 2 Local, A. Williams. *vhc*, H. J. Gurnell. 3, F. W. G. Gurnell. 1, J. K. Fowler. 2, J. Walker. 3, F. G. S. Rawson. 2 Local, J. Hutt. *vhc*, E. Pouting. E. Snell. **MARCHELON** of Hastings, J. Walker. **SELLING CLASSES**—Brahmas, Dorkings, Cochins—Cock—1, W. A. Eurrell. 2, E. Woodford. 3, H. Yardley. 4, H. Tomlinson. **Hens**—1, A. Darby. 2, S. Sambrooke. 3, Rev. T. C. Peake. 4, W. A. Burnell. *vhc*, C. Sidgwick, H. Yardley, H. Tomlinson, S. Salter. *Any other variety—Cocks—1, L. Garnett. 2, W. Nottage. 3, M. H. Sturt. **Hens**—1, J. J. Walker. 2, L. Garnett. 3, A. & W. H. Silvester. **BANTAMS**—Any variety—1, M. Leno. 2, C. Reed. 3, G. Hall. *vhc*, C. Naylor. R. A. Boissier. **DUCKS**—1, J. Hedges. 2, R. Gill. 3, T. Kingley. **PIGEONS**—CARRIERS—Blue or Silver—Cock—1, W. Massey. 2, H. Yardley. 3, W. Hooker. **Hens**—1, W. Hooker. 2, E. C. & T. H. Stretch. 3, W. Massey. **Young**—1, W. Jacob. 2, R. Cant. 3, E. C. & T. H. Stretch. *Any other colour*—Cock—1 and 2, J. Baker. 3, J. Harwood. **Local Prize**, W. P. Keall. **Hens**—1, E. Burton. 2, R. Cant. 3, J. Bentley. **Young**—1 and 3, R. A. Pratt. 2, J. Chandler. *vhc*, E. Barker. 3, J. T. Holmes. **BURBURY**—1, E. Palmer. 2, J. T. Holmes. 3, J. T. Holmes. **White**—Cocks—1 and 3, L. & W. Watkin. 2, J. Stiles. **Hens**—1, L. & W. Watkin. 2, Ridley & Dye. 3, Mrs. Ladd. *Any other colour*—Cocks—1, J. T. Holmes. 2, J. Baker. 3, H. Pratt. **Hens**—1, J. Baker. 2, H. Pratt. 3, L. & W. Watkin. **Local Prize**, W. P. Keall. **BARBS**—1, M. Headley. 2 and 3, R. W. Boyce. **Young**—1, H. Hedley. 2, R. W. Boyce. 3, J. Baker. **Local Prize**, J. Nunn. **TUMBLERS**—Almond—1 and 2, J. Baker. 3, H. Yardley. **Local Prize**, W. R. P. Keall. **Young**—1, T. Hanning. *vhc*, J. Hanning. *Any other variety*—1 and 2, J. Baker. 3, H. Yardley. **Balds or Beards**—Not Short-faced—1, H. O. Crane. 2, R. Woods. 3, F. Siedle. *Any other variety*—1, J. G. Fith. 2, J. W. Edge. 3, J. Barnes. **DRAGONS**—Blue—Cocks—1, W. Osmond. 2 and 3, W. B. Tegetmeier. *vhc*, H. Yardley, R. Leach, R. Shuller. **Silver**—Cocks—1, 2 and 3, R. Woods. 2, W. Osmond. **Silver**—Brown Bars—Cocks—1, 2 and 3, W. Bishop. **Red or Yellow**—Cocks—1, R. Woods. 2, K. Woods. 3, H. W. Sugden. **White**—Cocks—1 and 3, R. Woods. 2, W. Bishop. *Any other colour*—Cocks—1, 2 and 3, R. Woods. 2, W. Bishop. 1 and Local Prize, H. O. Crane. 2, G. F. Flanagan. 3, G. Prentice. **Silver**—Black Bars—Hens—1 and 3, W. Osmond. 2, R. Woods. **Silver**—Black Bars—Hens—1 and 2, W. Osmond. 3, R. Woods. **Silver**—Brown Bars—Hens—1, W. Bishop. 2, H. Yardley. 3, W. D. Richardson. **Red or Yellow**—Hens—1 and 3, R. Woods. 2, H. W. Sugden. **White**—Hens—1, W. Bishop. 2, R. Woods. 3, H. W. Sugden. *Any other colour*—Hens—1, Cup and 2, R. Woods. 3, W. Keeler. **Blue**—Young Cocks or Hens—1 and Cup, R. Woods. 2, G. F. Flanagan. 3, W. Smith. **Silver**—Black Bars—Young Cocks or Hens—1 and 3, W. Smith. 2,*

T. C. Burnell. **Silver**—Brown Bars—Young Cocks or Hens—1 and Local Prize, C. F. Herrieff. 2, W. Bishop. 3, H. Yardley. **Red or Yellow**—Young Cocks or Hens—1, R. Woods. 2, Hon. W. Sugden. 3, G. South. **White**—Young Cocks or Hens—1, C. F. Herrieff. 2, W. Bishop. 3, W. Osmond. *Any other colour*—Young Cocks or Hens—1, 2 and 3, R. Woods. **ANTWERPS**—Short-faced—1, F. Winsor. 2, J. Mantel. 3, J. Chandler. *vhc*, H. E. Wright. 4, F. Herrieff. **Not Short-faced**—1, Local Prize, and 2, G. F. Herrieff. 3, J. Baker. **Homing**—Cocks—1, F. Winsor. Equal 2, G. Cotton & J. W. Barker. **Master S. Salter**, Equal 3, G. Cox & W. Norris. C. F. Herrieff. **Hens**—1 and Extra 2, G. Cotton & J. W. Barker. 2, W. B. Tegetmeier. 3, Master S. Salter. **RUNTS**—1 and 2, T. D. Green. 3, H. Stephens. **OWLS**—English—1 and 3, J. Baker. 2, H. Verdon. **Local Prize**, F. E. Bulley. **Foreign**—1, R. W. Boyce. 2, J. J. Sparrow. 3, J. Baker. **NUBS**—1, J. Barker. 2, H. Mitchell. 3, J. E. Burdett. **TURBITS**—Blue or Silver—1, R. Woods. 2, G. H. Gregory. 3, E. A. Thornton. *Any other colour*—1, T. C. Burnell. 2, S. Salter. 3, J. Gargill. **FANTAILS**—1, J. Bailly. 2 and 3, Rev. W. Serjeantson. **JACOBINS**—1, 2 and 3, J. Baker. *vhc* and Local Prize, W. P. Keall. **MAGPIES**—Black—1, 2 and Local Prize, F. E. Bulley. 3, S. Salter. *Any other colour—1 and 3, S. Salter. 2, G. H. Gregory. **ANY OTHER NEW OR DISTINCT VARIETY**—1, J. Ponssett (Archangel). 2, J. Baker (Trumpeter). 3, J. Bailly. **Local Class**—Homing Antwerps—1, E. Newmann. *vhc*, and *thc*, T. Taylor. 3, W. R. Pratt. **SELLING CLASS**—Price not to exceed £3.—1, R. A. Pratt. 2, H. W. Hale. 3, L. & W. Watkin. *Price not to exceed £1*—1, R. Woods. 2, W. Massey. 3, W. W. Pyne.*

**JUDGES**—Mr. F. C. Esquilant, Mr. E. Hewitt, Mr. P. H. Jones, and Mr. R. Teebay.

## SOUTHWELL POULTRY, &c., SHOW.

The twenty-first annual Show of the Agricultural Society was held at Southwell on the 24th inst. The poultry Show in connection seemed to be an important portion. A good tent was provided, and Turner's pens were used, and the whole Show was well conducted, the Secretaries never leaving their post for any purpose.

**Game** (which headed the list and which in times gone by had their especial home in this district), were very badly represented, the class for Reds presenting nothing that fairly deserve special notice. In the next class first were Piles; and except that the cock was very thick and short in head, they were good, the rest being Duckwings. **Cochins** (Buff) were very good, the whole of the prizes falling to one yard. First and second to old, and third to young birds. The next class was not so good, although the winners were fair specimens. First and third Partridge, and second Whites. In **Dorkings** first and second were Dark, and third Silver-Grays. **Crève-Cœurs** a moderate class, some of the hens very good in head. **Houdans** a very good class, and all noticed in the list. Strange to say **Hamburgs** had but one class, the first going to a very neat pen of Blacks; second to Gold-pencils, the pullet in which was particularly good in marking, but the cock a little faulty in comb; the third Silver-spangles. In the Variety class first were Spanish chickens, as also the third; Gold Polish being placed second, these not being in full feather; but the hen particularly good in ground colour and marking. **Game Bantams** were the two best classes of the Show, the Reds being particularly good. First Black Reds, second Brown Reds, not up in feather but very good in colour, face, and eye; and third Black Reds, the pullet a little rusty on wing but very stylish. In the next class most were Piles, but first and third were Duckwings; the first very stylish and gamey, but not equal to the third in colour, the latter, however, being so far apart in colour of leg destroyed the chance of first, although if put singly these would quite walk in such competition. The next class contained nothing special, if we except the winners, which were first and third Booted, and second Black. Cross-bred fowls brought out birds quite to our idea—viz., short legs, long heels, and broad backs, and of great size, and from the Crève and Brahma cross. **Ducks** good in both classes. The Selling class was very good, first Crève-Cœur pullets fit for any competition; second Buff Cochins; third Spanish pullets; fourth Duckwing Game pullets.

**Pigeons** had but eight classes, and the prizes poor. In Carriers first a Dun cock; second a Dun hen; and third a Black cock. Pouters nothing of note except the first-prize Blue; Dragons, good, the prize falling all to one lot; and Fantails also a good lot, the first one of the best we have seen of late. In Turbitts, first was a small neat Silver hen; and second a Yellow cock. English Owls very poor except the first, and Antwerps had except the first Red Chequer and second Long-faced Blue Chequer. The Variety class was a good one in all respects, and duplicate prizes were given in the standards to an Almond, Barb, and Agate, and in others to a Pigmy Pouter, Spangled Ioe, Swallow, and Blondinette.

**POULTRY**—**GAME**—Black or Brown Reds—1, G. Doubleday. 2, W. Brinsley. 3, G. Barnesby. *Any other variety*—1, G. Barnesby. 2, Master E. Cope. 3, D. Hulme. **COCHINS**—Cinnamon or Buff—1, 2 and 3, W. A. Barnell. *vhc*, R. P. Percival. *Any other variety*—1, R. P. Percival. 2, R. A. Boissier. 3, W. A. Burnell. *vhc*, Rev. R. Fielden. **BRAHMAS**—Dark or Light—1, R. P. Percival. 2, R. E. Wood. 3, R. A. H. Robins. **DORKINGS**—1, R. P. Percival. 2, R. E. Wood. 3, R. A. H. Robins. **CRÈVE-CŒURS** or ANY OTHER FRENCH VARIETY, EXCEPT HOUDANS—1, J. Ward. 2, Miss A. Sharp. 3, E. A. Ward. **HOUDANS**—1, R. E. Wood. 2, E. A. Blair. 3, I. Ward. *vhc*, Thomas, J. E. Pilgrim, W. O. Quibell. **HAMBURGERS**—1, G. Bacon. 2, W. Speakman. 3, J. Ashworth. **ANY OTHER DISTINCT VARIETY**—1, R. Newbitt. 2, G. W. Boothby. 3, J. Aldridge. **BANTAMS**—**Game**—Black or Brown Reds—1, R. Swift. 2, Miss E. Crawford. 3, J. Oserott. *vhc*, Miss F. K. Winwood. 3, J. Smith. *Game*—Any other variety—1, Miss E. Crawford. 2, R. Newbitt. 3, Shumach & Dalt. *vhc*, W. Knight. 3, H. Hockaday. *Any other variety*—1, R. H. Ashton. 2, H. Ludlow. 3, F. Hobbs. **CRÈVE-CŒURS**—1, R. Ashton. **CROSS-BRED FOWLS**—Rev. J. Barrow. 3, H. C. Stenton. 3, E. V. Snell. *vhc*, Rev. J. Barrow. **DUCKS**—**Rothen**—1, W. H.

Robson. 2, W. Bygott. 3 and *vhc*, E. V. Snell. *Aylesbury*.—1 and 2, W. H. Robson. 2, E. V. Snell. *Any other variety*.—1 and 2, A. & W. H. Silvester. 3, R. H. Ashton. *Geese*.—1, W. H. Crewe. 2, E. V. Snell. 3, G. Daff. *SELLING CLASS*.—1, Rev. J. Barrow. 2, W. A. Burnell. 3, J. Aldridge. 4, J. Booth. *vhc*, Rev. E. Fielden. R. Newbitt. Miss E. Challen. *COTTAGES' CLASS*.—1, J. Payne. 2, G. Henfrey. 3, R. Spick. 4, H. Coddington.

**PIGEONS**.—**CARRIERS**.—1, H. Yardley. 3, C. G. Cave. **POUTERS**.—1, E. A. Thornton. 2, C. Young. **DRAGONS**.—1, 2, and 3, R. Woods. *vhc*, H. Yardley. **FANTAILS**.—1 and *vhc*, J. F. Loversidge. 2, J. Walker. **TURBITS**.—1 and 2, R. Woods. *vhc*, J. Wharham. **OWLS**.—*English*.—1, H. Parker. 2, H. Yardley. *vhc*, Miss K. Swift. **ANTWERPS**.—1, H. Yardley. 2, F. E. Edwardson. *ANY OTHER VARIETY*.—1 and 2, H. Yardley. 3, M. Weston. 4 and extra 1, A. and W. H. Silvester. Extra 2, R. B. Wood. Extra 3, —Clark. *vhc*, M. Weston. J. F. Loversidge. W. F. Footit, R. B. Wood, C. G. Cave.

**JUDGES**.—Mr. E. Hutton poultry and Pigeons, Mr. Hives also in Pigeons.

## AGRICULTURAL HALL POULTRY SHOW.

(Continued from page 374.)

It is, we fancy, twelve years since the metropolis has seen a poultry show. In the years 1852 and 1853 took place the great shows in Baker Street. The Cochin mania was then at its height, and the building was crowded with spectators almost to suffocation. We have a dim recollection of seeing two pens of Brahmas at the second of these shows, which were then looked upon as the last imported novelty. Again in 1864 there was a London poultry show, this time at the Agricultural Hall. Great advances had been made in poultry culture, but the visitors were few, the time of year (September) unfortunately selected, and the experiment not a success. After a fresh interval of twelve years has the Hall seen a feathered tribe, and with a very different result, for on the first day of the Exhibition, when we visited it, there seemed a goodly crowd, both of fanciers and non-fanciers, to admire the great strides which have been made in the perfection of exhibition poultry. The birds were well arranged round the gallery, carefully fed, for we saw none of those detestable collections of maize lying in the pens as one does at most shows, and, in spite of many disadvantages under which the Show had been originated, it was a large and magnificent collection. It must be remembered that the Show of poultry clashed with Oxford, one of the favourite poultry fêtes of the year, that it was tacked on as an afterthought to the Dairy Show, and that the schedule was changed at least once. However, a success it was, and we feel pretty safe in prophesying only the forerunner of far larger and more successful enterprises of the same kind in London. As at Bingley Hall, the birds were far too near the gas, and our own seem to have suffered much from the temperature. We hope another time to see the poultry on the ground floor. We would suggest, too, that a few attendants with some distinctive badge are desirable; we could find none, and twice had to stop people tormenting and attempting to injure birds. Defects there always are in first attempts, and on the whole we thought it a well-managed affair.

**Dorkings** had two classes, for Coloured, and Any other variety, which numbered twenty-seven, and nine pens. The first Dark pair were fine chickens, symmetrical in shape; the cockerel good in comb and feet, the pullet not so in the latter respect. Second were old birds, very large, but we did not like their colour, the cock's hackles being silver with an admixture of brown. The third were in many respects good, but not perfect in feet. We preferred some of the highly commended pens to the winners; pen 372 (Cresswell) contained a well-matched pen, with really white feet; 375 (Burnell) a magnificent very dark hen; 379 (Gee) a massive cock; 382 (Lingwood) a very deep and broad cockerel with crooked toes. In the other class all the prizes went to Silvers; first a well-shaped cockerel, with a hen capital in form and colour; second an adult pair, which promised to be immense when through the moult; third pretty but small chickens, the cockerel squirrel-tailed. We much preferred Miss Pasley's pen next to them. A good pair of Whites were unnoticed. **Hamburghs**.—In Silver-pencils the first cockerel was far a-head, a well-developed bird, with exquisitely laced tail; second a good pullet and younger cockerel; third a pretty little pair, young, and the cockerel with a good honest comb. The class as a whole was much better than we often see in the south. Silver-spangles were a large class; the first cockerel had rather a coarse and lumpy comb; second was a very pretty cockerel, with a large-mooned pullet; third cockerel had a black patch on the back. **Golden-pencils**.—The fashion seems to be in favour of black tails in this variety. The first pair were very good: the cockerel had lovely lobes and comb and rich colour, the pullet small fine pencilling. Second another very dark cock, but showing a little bronze on the tail; not quite so pretty in comb as the first. Third another dark black-tailed cockerel with good comb and lobes, the pullet coarser in pencilling than the other winners. **Golden-spangles**.—We have before remarked on a fact which was again patent in the Hall, that the hens of this variety are seldom in good condition. First a good pen, cockerel a model bird, his comb simply perfection; the cock in the second pen had a small comb, almost too small for a Spangle, good in colour, but without the carriage of the first; the cock in the third pen was well shaped,

but we did not admire his comb, and the hen was unevenly mooned. **Crêves** were only a moderate class in quality as in numbers; first were well-matched chickens with good crests, but not large, and the cockerel decidedly leggy; we thought the award a mistake. Second a fine hen, with a fair cock; his crest not yet moulted out. Third a rather high-tailed cock with small crest; another fine hen. **Houdans** were a large and excellent class, many birds which would ordinarily be certain of a prize being but highly commended or unnoticed. First a well-matched pair, good all round and in blooming condition; their colour rather dark. We have always thought that there is something distinctive in the head and expression of a true Houdan, and this the cock eminently possessed. Second cock not through the moult; very fine hen. Third grand dark birds, the hen splendid. 630 (Mr. Thomas) showed a very fine pair, thrown out apparently by the cock's bad feet. **Leghorns**.—White: first a well-matched pair, the cock pretty with a not abnormal comb. Second the whitest birds in the class, apparently young. We thought the cockerel in the third pen decidedly the finest in the class, but they were not well shown. **Browns**.—The awards were not up at 5 P.M. in this class, so we cannot comment on them. We thought a pair of Mr. Hitchin's birds the prettiest in the class. **Ducks**.—*Aylesbury*: first were entered as six months old. They are prodigies, and we were glad to see a first prize given to birds which looked healthy and not over-fatted; second were old birds; third young and good. **Rouens**.—First were a drake somewhat out of condition, and a handsome Duck; second not so good-looking a pair as might be expected, the Duck white in wing. Any other variety.—This was a large (twenty-four pens) and interesting class; first were Chilian Pintails, at least so we were told, but do not pretend to be learned in ornamental waterfowl; second lovely Black East Indians; third Pekins. They were grand-looking white birds with orange-coloured bills; these contrast beautifully with their plumage, and are (we are heterodox enough to think) much prettier than the flesh colour of *Aylesburys*. A curious pair of white-tufted Ducks were shown and highly commended. **Turkeys** looked fine and well-shown. **Geese** (twenty-two) were a wonderful class; first and third prizes went to Grey; second to White Embden.

We trust next year to see an Agricultural Hall poultry Show, with much-extended classification, and a more than proportionate increase of entries. The Judges were the Rev. T. L. Fellowes, Capt. Heaton, Messrs. E. Lowe, and M. Leno.

## THE OLDHAM SHOW OF PIGEONS, &c.

The second annual Exhibition of Canaries, Males, and British and foreign cage birds and Pigeons took place in the Temperance Hall, Horsedgate Street, Oldham, on October 25th, 26th, and 28th. The exhibits numbered 155 Pigeons and 314 cage birds. The former division comprised many fine specimens fit to grace the stages of any show. The classes for "Jacks," Owls, and Short-faced Tumblers, however, met with no response.

The cage birds, of which the Lancashire "Coppies" and "Plain Heads" formed a prominent feature, were a goodly lot, and far exceeded in number those at the previous show, and this was the more surprising considering that a show at Norwich was being held on the same dates. But the Hon. Secs., Messrs. Fleming and Bradbury, aided by a practical working Committee, entered into the spirit of their labours with a determination to succeed, and their creditable schedule brought forth an exhibition worthy of themselves and all others who participated in the affair. The pains and penalties paid last year in the Lizard classes had the creditable and beneficial effect of stamping out the artificial system of colouring so long carried on in the neighbourhood of Lancashire, and we heard it jocularly remarked that "one chemist had broke (?) since the new and more wholesome order of things had come about. This year the Lizards were a grand lot, and we never saw birds more beautifully spangled than some present, notably the first-prize birds in each class. Without entering into full critical details of the whole of the classes we will sum-up our report by saying that the competition here and there was so keen as to engage the attention of the Judge fully half a dozen hours ere his duties were finished. The awards are as follows:—

**PIGEONS**.—**POUTERS**.—*Cock*.—1 and *vhc*, H. Pratt. 2, D. M. Garside. *Hen*.—1, H. Pratt. 2, D. M. Garside. **CARRIERS**.—*Cock*.—1, J. Balmforth. 2, W. Deakin. *Hen*.—1, W. Lees. 2, J. From observations taken near London during forty-three years, the average day temperature of the week is 49.8°; and its night temperature 34.2°.

## VINE PESTS.

VERY little can be done towards thoroughly eradicating the various insects which affect the Vine until the leaves have fallen and the Vines are at rest. Of course the insects may be checked to a certain extent during the growing season, but winter is the time for their complete banishment. It is throughout the winter when every part of the Vine, wood and house, can be readily reached that the only opportunity occurs of making a thorough cleansing. As this period extends from November until March, a few remarks on the best means of destroying the most virulent of Vine pests may be of use to some readers.

**RED SPIDER.**—This is well known to be one of the very worst enemies the Vine-grower has to contend with. It is a very small insect, and it often becomes established before its presence is discovered. It never settles on the whole of the leaves at one time, but starts on one or two and spreads to the others. The only chance of keeping it down when the Vines are in leaf is to deal with it when it is on the first leaf or two. It may be detected by the leaves which it attacks assuming a slight brown tint; but those who know its habits best do not wait until it shows itself in that advanced form, but examine the back of the leaves from their earliest development, sponging them with soft soap and water immediately a spider is detected. It is rather a tedious operation sponging each leaf, but this when carefully done in time very often prevents further injury, and is very much better than any other subsequent attempt at a cure.

A dry atmosphere always fosters red spider, and when much fire heat is used to keep up the temperature the spider is always found first on the leaves nearest the pipes; these are the leaves which should be looked over and sponged. Daily syringing when the fruit is green does much to stay the progress of red spider, but this operation cannot be carried on with advantage when the fruit is ripening; and as it is generally in the midst of the hot summer weather when syringing must cease the spider then spreads with great rapidity. Mildew has been unusually prevalent this season, rendering, in many instances, a dry atmosphere necessary in order to check its spread—a condition precisely suitable for the increase of red spider, so that I am inclined to think the pest will be in great force this autumn. When moisture cannot be applied, such as when the fruit is ripening or hanging ripe, sulphur is frequently used with the intention of killing red spider. It is made into a paint-like mixture, and brushed on to the hot-water pipes or flues. The ventilators are closed in the evening, and the pipes are heated until the temperature of the house rises to 85° or 90°. The sulphur through being heated emits strong fumes, and these are said to kill the spider; but although I have carried out sulphuring thoroughly I must confess that I have never found it effectual.

As soon as the fruit is cut from infested Vines they

should have a complete and thorough syringing from the garden engine; this will dislodge a great many of the insects, which is very necessary, as they often interfere with the ripening of the wood. Than this drenching no other remedy need be applied until the Vines are pruned. In pruning, the whole of the shoots which are cut off should be taken outside and burned. All the loose bark should be peeled from the canes, but in doing this a very blunt knife should be used, and care must be taken not to cut into the wood. The spurs must be particularly well scraped without touching the buds for next year's wood, and the rods should be made quite smooth and clean from top to bottom. After this has been done all the glass and woodwork must be washed with soft soap and warm water, also the trellis to which the Vines have been attached; every inch of brick or stone work above and underneath the surface of the border for 3 inches should be limewashed. The rods must then be washed. For this purpose I cannot recommend anything better than a mixture of soft soap and water, which should be strong enough to colour the water so as the finger cannot be seen more than 1 inch below the surface. If this solution is properly used the Vines require no dressing with any mixture after they are washed.

I have known instances where the rods have been covered with a dirty mixture of soot, lime, &c., without previously washing or cleaning the canes. Instead of this "painting" killing the insects under the bark or destroying the larva it only keeps them comfortable, and they come out as fresh as ever when the Vines are started into growth. If a Vine is well cleaned of the loose bark and thoroughly washed it is quite impossible that any description of insect can escape, the whole of them will be washed down to the ground; and to complete the cleansing the surface soil of the border to the depth of 3 inches must be removed and replaced with a mixture of fresh soil and decayed manure. No matter to what extent a vinery may have been infested, if the above instructions are carried out not a spider need be seen next year.

**THRIPS.**—This insect, although not so destructive as the red spider, is nevertheless capable of doing much injury to Vines. In a young state it is white in colour, but as it becomes older it turns black. It is much easier seen than the spider. It has not much influence on the old leaves, indeed it seldom attacks them, but it is very partial to the young tender leaves and points of the shoots, and frequently stops the growth of these altogether. The leaves which it has been eating may be distinguished by small transparent spots which appear on them. Syringing is a good means of keeping the thrips from spreading, but this does not exterminate them. Fumigation with tobacco smoke accomplishes this more perfectly than anything I know. The vinery must be filled with smoke three nights in succession, and this generally has to be repeated two or three times during the season.

**MEALY BUG.**—Where plants are grown in vineries, which is very often the case, this insect is almost sure to find its way on to the Vines. It does less harm than

either of those previously mentioned, but it looks filthy, especially when it settles amongst the fruit, as it very often does when the bug is very plentiful. Nothing is more offensive than sending a bunch of Grapes to the table with a number of bugs crawling about it. Unlike many other insects it seems to exist as freely on the woodwork of the house, or in the crevices, as on the Vines. Little or nothing can be done towards destroying it while the Vines are in leaf, but the means taken to clear out the spider when the Vines are pruned will not fail also to extirpate mealy bug. Where it has been very abundant the inside woodwork of the house should be painted after it has been well washed. Oil, turpentine, and such like, which are sometimes recommended for this insect, I have a great aversion to and never use them, as I consider them not only unnecessary but often injurious.

**GREEN FLY.**—Although often collecting on the points of the young shoots does not appear to do them much harm, and this insect cannot survive the application which destroys the thrips.

**PHYLLOXERA VASTATRIX.**—Unfortunately this insidious pest must now be classed amongst the most destructive insects with which the Vine-grower has to contend. The only way of exterminating it is to make a thorough clearing-out of everything connected with the vineries. It was quickly and very cleverly eradicated from Drumlanrig in 1872, and I have not heard of any trace of it being found there since. Mr. Thomson in that useful book "Fruit-Culture under Glass," says, "The most certain way of stamping-out this destroyer is to burn the Vines, remove right away all the soil, well salt the site of the border, and wash and paint everything connected with the vinery before fresh soil is put into it."

**WIREWORMS.**—These are not often classed amongst Vine-destroyers. In some places they are said to injure the roots, while other good Grape-growers, such as Mr. Douglas, hold them to be harmless. However, if harm they do it is only to the young roots and newly-planted Vines when they are placed in fresh soil. As the fresh turves decay the wireworms appear to decay with them, especially when the grass roots perish. The soil which it is intended to use for potting young Vines is generally pulled into small bits with the hand, and while doing this all the wireworms which are seen should be picked out and destroyed. Those in borders require to be trapped; this is done in various ways. Perhaps the best is to put small slices of Carrot here and there underneath the soil, with a small peg in each, which must be left projecting above the soil to act as a handle for the purpose of lifting the bits of Carrot, which must be looked to frequently, and any of the worms found destroyed. The stems of Cabbage, Kale, or Brussels Sprouts, if cleaned and sharpened at one end and inserted into the soil, also act as traps for the wireworms, as they bore into the stems, from which they can be removed and killed. A little soot mixed in the soil makes it distasteful to them.

**MILDEW.**—This is not an insect, but it is equally destructive, and as the winter season is the time to deal with it, a few words on the subject may not be unacceptable. Sulphur is the great specific for this malady. It often appears in small wool-like spots shortly after the Vines are started into growth. It is more liable to spread in spring than summer, as a close moist atmosphere is favourable to its production, and in hot weather in summer the atmosphere of the vinery is not often either close or overmoist; but if mildew gains a wide footing in spring it sometimes continues to spread throughout the summer. From the leaves it passes to the fruit and then to the wood, where it shows itself in little dark-coloured spots, and if these marks are not removed when the Vines are pruned every leaf will become infested when the Vines are started into growth. When the canes are pruned and washed, as above recommended, a quantity of sulphur should be mixed into a paint-like consistency, and the whole of the rods should be painted over and allowed to remain in this state, when the parasite will be entirely killed before the Vines are started into growth. This plan is simple, and I do not think anything could be more effectual.—**VITIS.**

### WINTERING AURICULAS.

THE Auricula suffers more from damp during the winter than from frost; indeed, I think it is questionable if even very severe frost would materially injure the plants. But all cultivators are careful in excluding it as far as possible, because it unquestionably injures the bloom, cracking the paste, and

causing the flowers to come rough. Few of the old growers used to winter their plants in anything but wooden frames; but modern growers are more careful. Personally I have found frigi domo very valuable, and if "I. F. K." would procure sufficient of it, not only to cover the glass, but to go clear over wood and all, and have it double, I think he might defy frost. It is very cheap, warm, and durable. When once the plants begin to show the bloom, it is very desirable to keep them from frost, and one has often heard how some of the Lancashire weavers would strip the blankets off their own beds to cover their much-loved plants.—**D., Deal.**

### STANDARD ROSES.

THERE are those who appear to desire that standard Roses be driven from all gardens. I cannot join in such a wish, knowing as I do how greatly Roses of that character are prized in many gardens, and how much they contribute to the floral display of summer and autumn. I grant that there are some places quite unsuited for standard Roses, and some kinds of standards which are unsuited for any place; but, on the other hand, there are varieties which are valuable, and places for which they are particularly adapted.

The fashion for standard Roses, like that in the case of other fashions, has been carried to an extreme point. Standards must be had, therefore any Briar stalk will do, and the taller they are the better, appears to have been the principle of action. What wonder, then, that a reaction has set in, and that another extreme adopted—namely, extermination?

Standards are not suitable for exposed gardens, for districts where the winters are very severe, for dotting on lawns with the turf growing close to their stems, nor, it may be, in any place where blooms are grown wholly for exhibition. All that I readily grant, yet I know that standard Roses are useful, and I cannot join in the cry for their general uprooting.

Let us bear in mind that all who enjoy Roses are not exhibitors of them, yet many who do not exhibit are greatly and often profitably influenced by the teachings and advice of the exhibitors. From them valuable hints are derived on pruning, manuring, and other points of management, and more and better Roses have followed. But more and better Roses could not in all cases follow were the standards destroyed. There are gardens where, if standards were not grown, their owners would be almost destitute of Roses.

Standard Roses are most ornamental in mixed borders and amongst shrubs, where dwarfs would be quite inadmissible. It is conceivable that there are those who would consider it bad taste to plant Roses in such positions, and further, that Roses so grown cannot be worth looking at. Hundreds, however, there are who think differently, and so plant and enjoy Roses, and are ready to admit others, who in turn are ready to enjoy them too. Now these are not all destitute of taste, nor all bad judges. I will adduce one or two examples.

Turn to page 386 of last week's Journal and read "D., Deal's" notes on Mr. McIntosh's garden at Duneevan, and find these words:—"Does he [Mr. McIntosh] grow Roses? Well, in answer to this, just let me say that in one of his rooms is a table on which there are arranged 250 specimen glasses of various sizes, and these are kept filled all through the season with single blooms of Roses; and I rather fancy that anyone who can do this must be able to grow Roses." Many others, I assume, will fancy so too, and also fancy that "D., Deal," is not a bad judge of the blooms which he has deemed worthy of honourable mention.

Now, I happen to know Mr. McIntosh's garden. I have seen it when the rich collection of Rhododendrons have been in their glory, when the matchless Lilies have been in their zenith of beauty, and when the Roses have been blooming which produce the blooms keeping the "250 specimen glasses filled all through the season," and I think I am right in saying that but for standard Roses those glasses would be empty; and but for growing standards amongst the Rhododendrons that garden would be destitute of Roses. Who that has seen the Roses at Duneevan could despise them or the trees producing them—the oft-abused standards? Standard Roses, the heads just rising above the rich green foliage of Rhododendrons, have a beautiful effect, and are worthy of a better name than "mop-heads."

I will now refer to a garden a hundred miles north from Duneevan. A quarter of a century ago I planted amongst the shrubs in that garden a great number of standard Roses, and many of them are still growing luxuriantly and flowering pro-

fusely. In the 4-foot-wide flower borders (bounded by espalier trees) which fringe the walks of the kitchen garden are hundreds of standard Roses, which in their season of blooming are admired even by rosarians, and from these standards "bushels of blooms" have been cut and sent to cheer the inmates of hospitals and infirmaries. Dwarfs in such a situation would be but poor substitutes for the standards which have produced such a splendid effect and such gratifying results for many years. Dwarfs have been tried in some of the borders, and have been "found wanting."

A mistake commonly made with standard Roses, and which has more than anything else brought them into disrepute, is in having their stocks too tall. Briars have been planted of what was deemed the right height, in forgetfulness that 2 feet more would be added to them by the growth of the Roses.

Two feet or 2½ feet ought not usually to be exceeded as the height of the Briars before they are budded. They ought also to be selected with care, rejecting any with imperfect stems and insufficient roots.

Briars are condemned also for their natural propensity of producing suckers. True it is that Briars struggle hard for life, but with care in selection and planting, and generous treatment, keeping the Roses on them growing, a Briar will not give much trouble in growing from the roots. If its sap channels are impeded, then it will make others; but with a healthy stem and free growth at the top it will not greatly annoy by growing from the bottom. It grows from the roots, not in preference to growing at the top, but simply in preference to dying.

My practice in growing standard Roses is to select stout clean Briars with good roots and plant them in November, carefully examining the roots and rubbing off any buds which are seen previously to planting, and not allowing the roots to become dry by exposure. After the Roses are established they are pruned in the spring after growth has commenced. Superfluous shoots are thinned out, and superfluous flower buds from the shoots remaining. Insects are rigidly extirpated, and a few soakings of liquid manure are given to the roots. The Roses then grow with unchecked vigour, and suckers give little or no trouble because few are produced. When growths issue from the roots they are signs of bad management on the part of the cultivator or of disease of the Rose, which is making a last effort for existence by growing at the bottom because for some reason or other it cannot grow at the top.—A CIVILISED NATIVE.

### WINTER-DRESSING FRUIT TREES.

THE winter-dressing of fruit trees has been insisted on by most writers on practical gardening, no doubt acting on the principle that prevention is better than cure, the fact being that the remedy for a severely infested plant, whether with insect or fungus, is not unfrequently as bad as the disease itself. It has been held, and may still be held by some, that the winter-dressing of Vines, &c., is useless, as the insects are then dormant and proof against any insecticide. As to that I must confess to having but faint knowledge of insect life, and I do not think entomologists have placed before us the requisite information. Yet even a tyro in gardening knows that the brown or Peach aphid is as active upon the young shoots of the Peach and Nectarine during the winter as the summer months; that brown scale remains through the winter upon shoots which it has obtained a footing upon during the summer; that mussel scale holds tenaciously to the bark of Apple and Pear trees; that mealy bug and red spider, when the plants they infest become leafless, seek out the rough parts of the bark, beneath which they creep, shielded alike from cold and wet; that the whole tribe of aphides are more or less active during the winter months; and that thrips are not more given to pass the winter in obscurity than slugs. Now such insects abiding with the subjects upon which they feed are just as vulnerable to an insecticide in winter as at any other season, and often more so from their being more closely congregated; and further, the antidote being capable of application at a strength that would be fatal to the tender shoot and foliage, a winter-dressing is of much value.

I have tried most insecticides, and found all more or less useful. Nevertheless, from their costliness, and not always being at hand when wanted, I have thought some easily procured and readily prepared substances out of which an insecticide could at any time be formed would be desirable and acceptable. The following recipes will be found useful. Soft

soap half a pound, to which add a wineglassful of spirits of turpentine, and with a stick mixing thoroughly with the soft soap, having ready boiling tobacco juice, and adding this a little at a time, so as to incorporate the whole, the tobacco juice that is to be added being half a gallon. This small quantity will suffice to dress a dozen Vines or four average-sized Peach trees. Apply the mixture with a brush to every part of the trees after it becomes cooled to 120°, taking care to brush it in to the angles and crevices of the bark, and not to injure the eyes or dislocate the buds, which, however, should be coated with the stuff. The sooner it is applied after the leaves have fallen the better, as the pests remain as long as possible before retiring for the winter. The mixture will kill every species of scale (mealy bug not excepted), red spider, whether in the egg or otherwise; thrips, aphides, and fungus. It is only applicable to ligneous plants, and to those only when at rest. For destroying white or brown scale and mealy bug upon growing plants, 8 ozs. of soft soap mixed with a wineglassful of spirits of turpentine, adding gradually half a gallon of boiling water, stirring so as to thoroughly incorporate. Apply with a brush to the parts infected, or with sponge to leaves, at a temperature not exceeding 120°. The plants must be syringed with water immediately after they have been dressed with the solution, taking care not to allow the mixture to run down the stems in full strength to the roots.—G. ABBEY.

### HARDY SPRING ANNUALS.

As spring-flowering annuals are hardly ever done justice to except in very large establishments, I wish to draw the attention of amateurs and those who do not keep a regular gardener to the culture of a few of the best, which is very simple, and the cost of the seed is trifling. Amongst the most attractive are the *Silenes pendula rosea*, *pendula alba*, and *pendula ruberrima*. Each plant grows about 1 foot high and the same in diameter; they should be planted, therefore, about 1 foot apart either in lines, chains, or masses, and few plants will produce such a pleasing effect considering their cost. The seed should be sown about the third week in July, and the seedlings be transplanted once before the final planting in the flower garden where they are to bloom. One ounce of seed will produce about four thousand plants.

For a dark blue the pretty Forget-me-not, *Myosotis dissitiflora*, flowers early and produces a charming effect. The best way to raise a stock is to plant about one dozen plants in the spring, after they have done service in the flower garden, in a shady corner, and keep free from weeds, and in due time you will be rewarded with hundreds of healthy plants. For a yellow I have *Lasthenia californica*. It is a very showy annual, which does not attain more than a foot high, and is very free-flowering.—H. S.

### USEFUL APPLES.

OWING mainly to the articles of "A NORTHERN GARDENER" and "A MIDLAND FRUIT-GROWER" we have obtained a good notion as to what varieties of Apples, both dessert and cooking, we should plant if we want early Apples, and I know that early Apples are wanted both for parlour and kitchen. Awaiting, and glad of any further hints as to sorts—and very useful hints have been given in shorter articles than by the two writers above named—I would now say Let us proceed to the other end of the Apple season, and propose this question—"What varieties of Apples are best for the months of April, May, and June?"

As to the medium-season Apples there are plenty of those to choose from, and I think "A MIDLAND FRUIT-GROWER" did quite right to exclude the autumn Apples from his list of early sorts. By the way, I beg to thank that writer for his kind response to my request in his paper in the number of our Journal of the date of October 5th. Autumn Apples are not summer Apples any more than October is a summer month; and certainly Kerry Pippin is not a summer Apple.

My own opinion is that those who seek to place the Apple in a higher station as a fruit must try to combine beauty with utility. A handsome Apple is really a very ornamental object. Recently I was staying in Hampshire, and the staircase window commanded a view of the garden, and a very good and productive garden it is. Just within pleasant distance stood an Emperor Alexander Apple tree, turning a corner in espalier form. Its fruit was not yet gathered, and I never passed that window without pausing to admire the beautiful fruit, as at-

tractive to the eye as a *Pæony* in a shrubbery. Beauty and utility, say I. As to great size, most large Apples fail in flavour. The smell of the uncooked fruit is a good guide as to its taste when cooked. If I know the Greasy Coat, and I am not sure I do, but I was familiar with one answering to the written description, and its smell and taste when cooked were none too pleasant.

I see that several correspondents have not spoken favourably of the Devonshire Quarrenden, neither can I. Usually I have found it here dry and tasteless, with nothing but its red—over-red—cheek to commend it to the purchaser. But districts differ as to the quality of their fruit. Thus I was talking recently to the head gardener of a large establishment, and he stated that the soil was such that he could not properly ripen any Pears after Baurré Hardy and Baurré Diel, and that all the rest had to go for kitchen purposes.

After discussing the best early and late varieties of Apples, and these are the most valuable, it would be an almost equal benefit to open the subject of early and late Pears, fixing localities where certain varieties do best. A glaring instance is the Scotch Achan—north of the Tweed so good, in the south so bad—yet it is not quite alone, or there would not be such a difference in fruit character as noted in books, and catalogues, and articles, and the experience of fruit-growers. I examined a Ribston Pippin tree the other day, there was not a trace of canker on it; yet how many localities show nothing but cankered trees of that variety of Apple.—WILTSHIRE RECTOR.

### FORCING SPIRÆAS.

THERE is only one variety of *Spiræa* which is generally forced, and that is the old *Spiræa japonica*; but there are three others which I wish to bring under the notice of your readers as being equally worthy of the attention for greenhouse or conservatory decoration.

These are *S. palmata*, *S. Aruncus*, and *S. filipendula flore-pleno*. *S. palmata* forms an excellent contrast to the white-flowering kinds, as it produces very fine heads of purple-red flowers. The stems are crimson, and the leaves green, so that when well bloomed it forms one of the most handsome of plants. *Spiræa Aruncus* bears a mass of feathery panicles of pretty white flowers, which I consider more effective than those of *S. japonica*. *Spiræa filipendula flore-pleno* has extremely graceful leaves, being Fern-like, and although it is not quite so well adapted for forcing as the others named, it is worth growing in a pot for its ornamental habit. It also bears large heads of flowers of a creamy hue.

Those beginning to force *Spiræas* for the first time will require a quantity of roots, which may be bought cheaply from any nurseryman. The present is the best time to purchase them. They will be found to be compact roots, suitable for 5 or 6-inch pots. A light sandy loam may be used in potting, and it should be pressed very firmly about the roots to save watering, as great quantities of water will be required further on.

Newly-potted roots should be covered with a few inches of ashes for a fortnight or three weeks, and subsequently be introduced to any structure where the heat is about 60°. The leaves will soon appear provided the plants are supplied with plenty of water.

There is no genus of plants more easily forced, and they may be brought into bloom without much trouble, and when they are in flower they are valuable for bouquets or any other ornamental purpose.

By introducing into heat a dozen plants now and again, a succession of flowers may be had from December until May. If the weather is cold or frosty when they have done flowering they should have the protection of a frame until they can be placed out of doors for the summer. Here two courses of treatment may be followed. The one is to retain them in the pots and grow them in this way throughout the summer; the other is to turn them out of the pots and plant them in a border. I prefer keeping them constantly in pots, shifting them into larger pots when necessary, and plunging them to the rims in hot weather. They require a little more attention in watering when kept in pots, but they start more readily into growth when placed in their forcing quarters.

In planting them out they may be set a foot or more apart, and here also they must be liberally supplied with water in dry weather. They should be lifted out of the ground not later than the end of October, and potted in the same manner as the roots which were started with at first. When a few good

roots have been secured the stock may be increased by dividing them in spring and growing the divisions on as established plants.—R. J. N. M.

### LIATRIS PYCNOSTACHYA.

WE made a note of this beautiful hardy flower last month; since then the effect of the drought on summer-flowering plants has been counted up, and the result in favour of this is so striking that in the hope of a more general introduction we have had a sketch made of one as an illustration. Through the greater part of the month of August it was in full blossom, as if the heat, so destructive to many plants, was a matter of no consequence to it.

Fig. 60.—*Liatris pycnostachya*.

The plant is found wild abundantly throughout the States of Kansas and Texas and in the Indian territory, and though long known to botanists, and now and then sent east by correspondents during the past dozen years or more, no attempt to introduce it to general notice has been made that we are aware of. During the past summer we saw a whole row of it in the garden of a florist, and the effect of so large a quantity was beautiful in the extreme. The plants were raised from seeds brought originally from Southern Kansas in 1873. If sown in the autumn the plants bloom the next year, but the best success follows when sown in the spring, and the plants have a season's growth before flowering the next year. The roots are somewhat bulbous, and will continue to bloom well for several years. There are some twenty species in North America, but this is, perhaps, the handsomest of the whole. The flowers are rosy purple; spike about 1 foot long, as shown in the engraving. They commence flowering at the top of the spike, and the blooming progresses downwards. In the illustration the lower blossoms have yet to open.

Like so many beautiful plants from the West, this has not been known long enough to have an English name, and we suppose the Greek one will be considered "hard" by the dear ladies, and "pedantic" by the average man. The settlers call it "Fire-weed," and "Sky-rocket Plant," but as these names are already given to scores of plants, and will be to as many more, it is hardly worth holding on to them. The eastern *L. scariosa* is known as "Gay Feather;" suppose we all agree to call this the "Kansas Gay Feather." There are other species of *Liatris* in Kansas, but this is the best.—(*American Gardener's Monthly*.)

### WHITE ISCHIA FIG.

AT this late season, when all kinds of fruits are scarce, I may be excused for pointing out to those contemplating planting a very valuable Fig, and though a small one is nevertheless a very good and delicious fruit. I allude to White Ischia, which has several synonyms, the last being Singleton. We had occasion to turn one of our span-roofed Vine houses into a Fig house. The house is 60 feet long by 20 feet wide. The sorts I selected were Brown Turkey and White Ischia, two trees of each; one of each planted on either side. This is their

second season of growth, and I have given them next year to fill the house, including the 8 feet upright. This year the produce of all the trees have been great, and we are just now gathering every other day several dozens of fruit from the White Ischia, and the branches are still laden like ropes of Onions. Although this variety is considered a dwarf-growing tree in its planted state, here it has made a wider and stronger growth than its companion. It is a very small fruit grown in pots, but planted out it is nearly equal in size to White Marseilles. I find it of very great value just now, when Plums and Peaches are nil. It is well described in Hogg's "Fruit Manual," and its late usefulness added here may induce it to become useful also to a few others.—K.

### THE ROSE ELECTION.

AFTER all it is sufficient that our pets, the Roses themselves, have thorns with which they will sometimes inflict wounds on their admirers. It is not at all necessary that their admirers should have thorns for each other. In replying first in the heat of the moment, and with scant time for reflection to my friend—for I believe that "differences of opinion should not alter friendship," and therefore I still write my friend "WYLD SAVAGE"—I hope the side I showed was not too thorny. It was a terrible knock-down blow to have that heap of adjectives hurled at the election, for the publisher evidently was at a loss to select one more "jolly" than those "WYLD SAVAGE" had himself discovered; and to feel thus after having had Rose on the brain for weeks, after wading through names of illustrious and unknown personages who have given their names to the said Roses; after a nightmare in which each Rose has pressed its charms upon me for niches in the temple of Fame (*alias* Rose lists), and striven to assure me that each separate pleader should head the list, as if the whole matter rested with the returning officer instead of the voters; to have so redoubtable a champion as "WYLD SAVAGE" ride into the lists, determined to "do or die" for Marie Van Houtte or La Belle Lyonnaise, was in truth appalling, and like a bucket of cold water unexpectedly poured down your back in the depth of winter. But as many of us know that to the cold water there is a "jolly" reaction, so is there after "WYLD SAVAGE'S" cold douche, for private letters and your esteemed correspondents, including my friend "WYLD SAVAGE," have salved over any wound that the thorns had made.

I should, indeed, be ungrateful did I not acknowledge warmly the kind expressions of thanks for what really has been a labour of love, as "D. Deal," puts it. It is a labour, too, which makes me feel that I know some of the correspondents of our Journal as well as possible, even though I have never had the great pleasure of grasping their hands, for tied as I am professionally, spare moments do not come sufficiently together to enable me to visit exhibitions where I might see them in the flesh. To all who have written so kindly my hearty thanks are due, and if they are herein given but feebly, I can assure them they are most warmly felt.

If able and spared to undertake the 1877 election, it will be in some respects more in accordance with "Savage" ideas. It will be an "exhibition" and "garden" election, and the only punishment I shall inflict on "WYLD SAVAGE" will be that he must himself induce "Hercules" to put pen to paper for the former.

I will in conclusion just remark, that the difference of a vote more or less has a very marked effect on the position of a Rose at the close of the poll. Take for instance "WYLD SAVAGE'S" Duke of Wellington, which he justly remarks is so much higher in the supplementary list. Deduct from it one first-class vote, and 27 immediately becomes 33—a startling difference. So shaking hands with "WYLD SAVAGE," who is neither so *wyld* or so *savage* as his first onslaught appears to be, I again say to all helpers, Many thanks.—JOSEPH HINTON, *Warminster*.

### BEDDING GERANIUMS.

"C. P. P." appears to have an unlimited supply of Mr. Pearson's varieties, but there are sorts of other good growers which he never alludes to, let alone the good old varieties. What a small list of Roses there would be if all the old varieties were discarded! I was much struck by the following remark of a lady on looking at a bed of *Lucius* Geranium:—"I cannot bear those large heads, for they are always shabby in the middle before they are out at the sides." And is not this

what we all regret, and therefore should aim at kinds having good trusses and all the flowers opening together? If large growers would send well-tested lists it would aid many who, like myself, rejoice in a really good new variety, but who are often disappointed at finding some that they have been recommended to buy not being so good as they expected. Mr. Cannell's division of the colours into sections might suit, putting z for Zonal, n for Nosegay, and w when the flower has a white eye.—AGE.

### EARLY APPLES.

It is not a little humiliating to one, but I feel I must confess that at the age of fourteen to sixteen years old I knew more about early eating Apples than I do now. This is simply because I have not since had the rich store of varieties to practise upon. I then undoubtedly made good use of the opportunity, and could tell where the best fruit were to be found at any time. I knew each one's season of ripening, and I was not to be deceived in the name of an Apple by eating it in the dark. I knew, too, how to get a long pointed stick and take the Apples through a certain hole in winter from the fruit-room. I was particularly acquainted with most of the Apples mentioned of late in this Journal, but none of them equalled a favourite of mine, called "Vann's Pippin." I think it is a local variety, for I have not met with it in any other place. To me it seems that this Apple is to other varieties what a well-ripened Green Gage Plum is to an Orleans; indeed, like the Green Gage, the riper Vann's Pippin is it the more delicious. We find many Apples after being ripe pass to a dry mealy state, but not so this variety. It is at the same time the best early cooking Apple I ever met with. The tree is a prodigious bearer. I have known really good crops the second year when grafts have been placed on large trees.

I have not seen this Apple for more than twelve years, but writing from memory I would describe the fruit of medium size, in colour pale straw, conical; eye close and small, and set in a shallow basin, and stalk long and slender set in a rather deep cavity. It is an Apple that I can strongly recommend to any person; "WILTSHIRE RECTOR," I feel sure, would be pleased with it. I know no nurseryman who sells it, still I have no doubt that grafts or trees are obtainable.—JOHN TAYLOR, *Hardwicke Grange*.

### HARDY FLOWERS IN KEW GARDENS.

SAXIFRAGA FORTUNEI is now the most ornamental of all the herbaceous and alpine plants at Kew. A profusion of pure white flowers are borne above a mass of very handsome dark green leaves. This plant is on the rockwork, where it is quite hardy. *Oxalis lobata* is one of the gems of the genus, and is perfect in its habit of growth. It forms a neat tuft of leaves close to the ground, and on short stems above appear a multitude of golden yellow flowers. *Polygonum vaciniifolium* is another very elegant plant for rockwork; it has the most delicate spikes of pink flowers imaginable, produced on wiry stems with small leaves.

Several autumnal *Croc*i are now in flower, and it can but be said that they are deserving of far more attention than they receive in gardens. *C. Boryi* is one of the most beautiful of all *Croc*uses; its flowers are creamy white with orange-red stigmas. *C. cancellatus* is another white kind, easily distinguished by the coarse thick coats of the corm, though it may be said that all the species can be known by characters afforded by the corm. *C. longiflorus* has fragrant lilac flowers with a yellow throat. It is often called *C. odoratus*. *C. serotinus* and its variety *Salzmannii*, have also lilac flowers. Both are rare. *C. byzantinus*, sometimes known as *C. iridiflorus*, is blue-purple without variegation. It is remarkable for the small size of the inner perianth segments. *C. nudiflorus* is one of the most common, both wild and cultivated; it increases freely, and is naturalised about Nottingham and in two other districts. The flowers are blue-purple. *C. speciosus* is one of the largest and most effective; the feather-veining is beautifully apparent from the darker colour of the veins. It might be largely used for greenhouse decoration, and would be valuable, as flowering naturally at the present time when flowers are scarce. The trouble need receive no consideration, as the corms only require to be potted from the open ground when the buds are visible. No more roots need be taken than can conveniently be managed, though without doubt it would be best to accommodate as many as possible. In a dry room with fire a corm

without roots has just developed a perfect flower from a small bud.

A beautiful variety of the Strawberry Tree (*Arbutus Unedo*) is flowering on the lawn between the Cactus house and the old museum. The flowers are nearly twice as large as those of the common form, and moreover on the exposed side have a deep crimson blush, to which chiefly is due the great attractiveness of this variety. The leaves, too, are of greater breadth than in the type, and the stems more decidedly red. It is quite distinct, and deserves to be well known both as an ornamental shrub and as a floral ornament.

## ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 8TH.

WHATEVER impediments have had to be encountered in endeavours to extricate the Society from its difficulties and place it on a satisfactory basis, the Council have been encouraged by many expressions of confidence on the part of those immediately connected with horticulture. Ever since the great exhibition so spontaneously and gracefully made last year by the principal nurserymen, the exhibitions and meetings have been extremely gratifying. The Committee meetings have especially been well attended, and many subjects of great importance have been submitted at these practical and undemonstrative gatherings. But for respect for the "old Society," and faith in the policy of those by whom it is represented, the meeting of to-day would have been a comparative blank, for the great show appointed to be held was officially abrogated, and there was left only private enterprise and public zeal to atone for the sacrifice which it was found necessary to make. It is this enterprise and zeal which have made the Exhibition of to-day—another instance that horticulture is neither dead nor dying—another proof that the Royal Horticultural Society enjoys the confidence of many friends.

The only prizes offered on this occasion were those provided by the firms of Messrs. Carter & Co. of High Holborn and Messrs. Sutton & Sons of Reading. These prizes were liberal, and were responded to with collections worthy of the repute of the seedsmen and of the cultural ability of the exhibitors. But besides this competition there were honorary contributions of great merit, extent, and variety.

Messrs. Veitch were not afraid of bringing from their stoves valuable Orchids on the sharp frosty morning, nor Mr. B. S. Williams plants similarly tender. Mr. Willis also staged some of his new *Dracenas*; Mr. Ollerhead, gardener to Sir Henry Peek, Orchids; Mr. Smith, Ealing, and Mr. Lowe, Uxbridge, Cyclamens; Mr. Turner, Slough, a grand collection of *Chrysanthemums*; Messrs. Veitch & Sons also sending a collection with very fine blooms. These with the Grapes from Mr. Wildsmith, the Pines from Mr. Hunter, and the splendid collection of Pears and Apples from Mr. Haycock, gardener to R. Leigh, Esq., Barham Court; and from Mr. Ford, gardener to W. E. Hubbard, Esq., Leonardslee, Horsham, and numerous other exhibits, quite filled the Council-room and French courts, and made one of the most interesting exhibitions that has been seen for some time.

Mr. Turner's *Chrysanthemums* were vigorously-grown well-bloomed plants, the large-flowered varieties occupied the whole length of the long court, with Pompons at the end of the room. Time does not permit an enumeration of the varieties, which embraced all the best in cultivation. Messrs. Veitch's plants were noteworthy for their superior blooms, and the standard Pompons also staged by this firm were extremely effective. Messrs. E. G. Henderson & Sons, Wellington Road Nursery, also exhibited plants in exuberant health and with fine blooms.

The Grapes exhibited by Mr. Wildsmith comprised Burchard's Prince, Bowood Muscat, Lady Downe's, White Tokay, Gros Colman, White Nice, Gros Guillaume, Calabrian Raisin, Mrs. Pince, Muscat of Alexandria, Alicante, Trebbiano, and Black Hamburgh. Many of them were exceedingly fine, notably Gros Guillaume, Gros Colman, Lady Downe's, and Bowood Muscat.

The fruit from Mr. Haycock comprised thirty-seven dishes of Apples and twenty dishes of Pears, every variety being in really splendid condition; indeed finer fruit has seldom, if ever, been staged. The Calville Blanche Apples were of enormous size, and really splendid were Beauty of Kent. Cox's Pomona, Reinette d'Espagne, Reinette du Canada, Ribston Pippin, Emperor Alexander, &c., were in a perfect state, and particularly attractive was the Lady Apple, Pine Apple Pippin, and other small kinds. The Pears also were of equally high merit, Doyenne du Comice, Triomphe de Jodoigne, Beurré d'Anjou, Easter Beurré, Winter Nelis, Olivier de Serres, Beurré Bachelier, and some others, being represented by dishes of unusual excellence. This fruit was grown on the French system on horizontal and diagonal cordons, the Apples being on Paradise stocks. Mr. Ford staged fifty varieties of Apples and twenty of Pears, most of the dishes being highly creditable. Mr. Earley, The Gardens,

Valentines, Ilford, staged twenty-four varieties of Apples and Pears, including some good dishes. Mr. Fanning, gardener to Madame Digby, Roehampton, staged thirty-two admirable dishes; and Mr. Pragnell, gardener to G. D. W. Digby, Esq., Sherborne Castle, Dorset, eighteen dishes of excellent fruit.

Mr. Osman, South Metropolitan Schools, Sursey, exhibited magnificent heads of Veitch's Giant Cauliflower; Mr. Gilbert, Burghley, Canadian Wonder Beans; Mr. Parsons, Welwyn, superior examples of Magnum Bonum Onions; Mr. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, a dish of Ross's Criterion Potato, resembling Schoolmaster. Mr. Turner, Slough, exhibited a splendid dish of Schoolmaster, Bailey's Red Beet, Early Jaulin Savoy, very superior, and Bailey's Selected Cabbage, which is evidently a variety of great merit. Mr. Brown, gardener to F. T. Barry, Esq., Clock House, Beckenham, staged very large Celery—Grove White and Leicester Red; and Mr. Sidgar, Hammersmith, exhibited eighteen excellent heads of Celery in six varieties. A very numerous and superior collection of Potatoes, Onions, Gourds, &c., were exhibited by Messrs. Carter & Co.; and a similarly large, varied, and excellent contribution, including also Succulent plants, came from Mr. R. Dean, Ealing. A cultural commendation was awarded to Mr. Pragnell for an excellent collection of salad vegetables.

PRIZES OFFERED BY MESSRS. JAMES CARTER & CO.—For the prizes offered for twelve Pinesfield selected white Spanish Onions fifteen competed, the prizes going to Mr. Cross, gardener to J. Hough, Esq., Peak House, Sidmouth; Mr. Cave, Pinesfield Farm, Rickmansworth; and Mr. Neal, gardener to P. Southby, Esq., Bampton, Oxon, in the order named. All the bulbs being fine, the first-prize lot being highly superior and decorated with the "blue ribbon."

In the class for the best ten dishes of vegetables, including Carter's Heartwell Early Marrow Cabbage, ten competed, the first prize going to Mr. Pragnell, gardener to G. W. D. Digby, Esq., Sherborne Castle, Dorset, for a grand collection; Mr. Miles, gardener to Lord Carington, being second, also with splendid produce; Mr. Baker, Broad Street, Brompton, Farringdon, being placed third; and Mr. Lumsden, Bloxholme Hall, fourth. The vegetables in this class were of very high quality and won general admiration.

In the class for eight dishes of Potatoes, including Carter's Ashtop Fluke, Carter's American Breadfruit, and Porter's "Excelsior," eight competed. Mr. McKinlay, Beckenham, Kent, was placed first; Mr. Miles, Wycombe Abbey, second; and Mr. Baker, Brompton, Farringdon, third; the fourth prize-winner we could not ascertain. The tubers were extremely fine throughout these collections.

In the class for three specimens of Carter's Heartwell Early Marrow Cabbage, twelve competed. Mr. Neal, Brompton, being placed first; Mr. Pink, The Gardens, Lee's Court, Faversham, second; and Mr. Baker, Brompton, third. All staged superior examples of one of the finest sorts of Cabbage in cultivation.

PRIZES OFFERED BY MESSRS. SUTTON & SONS.—For twelve Sutton's Improved Reading Onions. First, Mr. G. Neal, gardener to P. Southby, Esq., Bampton, Oxford; and second, Mr. W. Cross, gardener to J. Hough, Esq., Peak House, Sidmouth. Eight exhibited in this class, and neither Messrs. Sutton nor the public could find fault with the produce.

In the class for a collection of Potatoes, twelve dishes, distinct kinds, grown by the exhibitor, six dishes round, and six dishes kidney. First, Mr. P. McKinlay, Woodbine House, Beckenham, who won the gold medal with Porter's Excelsior, Emperor, Redskin Flourball, Model, Scotch Blue, Climax, Salmon Kidney, King of Potatoes, Snowflake, Hundredfold Fluke, Purple Ashleaf, and Excelsior Kidney. Second, Mr. J. Pink, The Gardens, Lee's Court, Faversham (silver medal). Third, Mr. Lumsden, gardener to Sir R. C. N. Hamilton, Bloxholm Hall, Sleaford (bronze medal). Seven competed.

A collection of vegetables, twelve distinct kinds, including Sutton's King of the Cauliflowers, Sutton's Improved Reading Onion, Sutton's Student Parsnip, Sutton's Sulham Prize Celery, and Sutton's Improved Dark Red Beet. Mr. Pragnell, Sherborne Castle, won the gold medal; second Mr. R. Gilbert, gardener to the Marquis of Exeter, Burghley, Stamford (silver medal); and third Mr. Lumsden (bronze medal). Eight competitors.

The several collections staged in competition for all the above prizes were of highly superior quality, and it was no easy task for the Judges to decide on the relative merits of the produce of the successful competitors.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Williamson, gardener to C. N. Hatten, Esq., Bellair, Dulwich, sent two Pine Apples, one of which was the variegated variety and the other the Queen, and a letter of thanks was awarded. Mr. Woods, gardener to E. W. Walker, Esq., Bury Hill, Mansfield, sent two Pines which were passed.

Mr. Newton of Newark-on-Trent sent two bunches of Grapes, one Châpail and the other Black Damascus. The latter was of good flavour, but the other was not possessed of any particular

merit. Mr. Gilbert, The Gardens, Burghley, sent two seedling Apples, Captain Nares and First Lord, but they did not possess any merit superior to other varieties of this season. Mr. Gilbert also exhibited an Enville Pine. A fine basket of Trebbiano Grapes was also exhibited by Mr. Gilbert. The fruit was finely grown, well coloured, and of excellent flavour. A letter of thanks was unanimously awarded. A dish of very handsome Blenheim Pippin Apples and a dish of Uvedale's St. Germain Pear were exhibited by Captain Greville, R.N., Osmanthorpe, Laleham. A letter of thanks was awarded.

Mr. Woodbridge, The Gardens, Sion House, Isleworth, sent fruit of the *Diospyros Lotus*, for which a letter of thanks was awarded. The fruit is small and oblate, the size of a large pea, and yellow. F. W. Yorke, Esq., Oundle, sent a seedling Apple, which was not superior to other varieties already in cultivation. Mr. B. Spooner of Harrow, Middlesex, sent a seedling Apple like a large yellow Ingestrie, which was passed for the same reason. Mr. Clark, gardener to the Rev. A. D. Stackpole, Writtle, Essex, sent five dishes of Marie Louise, Uvedale's St. Germain Pears, and Margil and Ribston Pippin Apples, and fruit of Black Hamburg Grapes ripened out of doors. A cultural commendation was awarded for Marie Louise, and a letter of thanks for the rest of the collection. Stephen Swanston, Esq., Glastonbury, sent fruit of a seedling Pear found growing in a hedge. The fruit possesses considerable merit, and has a fine rose-water flavour. The Committee expressed a desire to see it again, with particulars as to its origin. Mr. G. F. Wilson, F.R.S., Heatherbank, Weybridge, sent a dish of the fruit of *Diospyros Kaki*, a Japanese fruit, to which a cultural commendation was awarded.

Mr. Bennett, Rabley Gardens, Herts, sent a pot of *Vicomtesse Héricart de Thury* Strawberry under the name of Garibaldi, full of fruit. Fruit of Golden Queen and Mrs. Pearson Grapes were exhibited by Mr. J. R. Pearson, Chilwell; both of these had received certificates on former occasions. The bunches were very large and handsome, and the flavour excellent. A cultural commendation was awarded. There were thirteen varieties of Grapes shown from the garden of the Society at Chiswick. A seedling Grape was exhibited by Mr. Tillery of Welbeck, raised between Lady Downe's and West's St. Peter's, but it was not considered of great merit. A fine collection of thirteen varieties was also sent by Mr. Tillery. Mr. Wildsmith, gardener to Lord Eversley, Heckfield, sent a large collection of Grapes, among which were Venn's Black Muscat and Muscat Hamburg. The former was very much shrivelled and richly flavoured. In the opinion of the Committee the two varieties are quite distinct. G. D. W. Digby, Esq., of Sherborne Castle, sent four very handsome Smooth-leaved Cayenne Pines, to which a cultural commendation was awarded.

**FLORAL COMMITTEE.**—W. B. Kellock, Esq., in the chair. Messrs. Veitch & Sons' collection of plants in the Council-room was extremely attractive. It comprised *Crotons Disraeli*, *Macafeanus*, and *Picturatus*, all highly superior; *Dracaena Hybrida* and *Taylori*; *Rhododendrons* Princess of Prussia and Duchess of Edinburgh, very handsome. The Orchids embraced *Oncidium ornithorynchum*, *tigrinum*, *papilio-Kramerii*, and *Wiltoni*; *Vanda cœrulea*, *Zygopetalum Mackayi*, *Odontoglossum Alexandræ*, *Miltonia Moreliana*, *Cattleyas* *Fausti exoniensis* and *Dominianum*, *Pleione maculata*, *Cypripedium Maulei* and *Sedeni*; also *Calanthes*. The collection also included the beautiful *Maranta Massagena* and a remarkable plant of *Hæmanthus cinnabarinus* with three extraordinary heads of flowers. A vote of thanks was awarded. Sir Henry Peck's Orchids—comprised *Pleiones*, *Cypripediums*, *Oncidiums*, *Cattleyas*, *Vandas*, &c., and a vote of thanks was deservedly awarded to Mr. Ollerhead for the collection.

Prominent in Mr. Williams's fine group were *Cycas intermedia*, *Odontoglossum grande*, *Oncidium macranthum* and *O. Barkeri*, *Adiantum digitatum* and *A. gracillimum*, *Masdevallias*, *Crotons*, *Cypripediums*, and a well-flowered plant of *Eucharis amazonica*. Mr. Wills exhibited a large group of Palms and other decorative plants, and the thanks of the Committee were awarded for both these collections.

A remarkably well-flowered plant of the beautiful *Dendrobium Wardianum* was sent by W. H. Michael, Esq., for which a cultural commendation was deservedly awarded. Mr. Wills submitted small plants of *Dracæna Carolette*, the foliage being regularly and brilliantly marked. It is a plant of the greatest excellence for dinner-table decoration, and was well worthy of the certificate which was attached. Mr. Strahan, gardener to P. Crowley, Esq., Waddon House, Croydon, received a first-class certificate for *Casuarina sumatrana*, a plant of the greatest elegance for table decoration. Mr. Dean exhibited Lee's Prince Consort Violet, the finest and sweetest of Violets. Mr. Westcott, gardener, Baby Castle, Darlington, staged *Capsicum* Princess of Wales, the plants being robust and laden with bright yellow pods. The Hon. and Rev. J. T. Boscawen, Lamorran, Cornwall, exhibited *Lilium neilgherrense*, one of the finest of trumpet-shaped *Liliums*. Mr. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston-on-Thames, and Mr. Baker,

gardener to W. H. Punchard, Esq., Twickenham, exhibited excellent cut blooms of *Chrysanthemums*, and received the thanks of the Committee.

Mr. Turner, Slough, exhibited the new perpetual-flowering *Carnation* Scarlet Dragon, which received a first-class certificate. It is not only the finest of *Carnations* of its section, but is one of the most valuable of all plants for winter flowering. Mr. Gilbert, The Gardens, Burghley, sent double *Primulas* with very fine flowers. Mrs. Laxton, Mrs. Barron, Lady Laura, and Ne plus Ultra being almost identical, blush white tinged with pink; Princess Louisa being the best of the rose-coloured varieties.

Messrs. E. G. Henderson & Son exhibited *Coleus* Pine Apple Beauty, very gay and the best of the Lady Burrell type. The same firm also exhibited *Kyllingia* monocephala, a distinct and elegant Grass, and Mr. Wildsmith a seedling *Echeveria*. Mr. Smith, Ealing, and Messrs. Lowe, Uxbridge, had votes of thanks for their excellent collections of *Cyclamens*, and a similar award was made to Mr. Cannell for zonal *Pelargonium* "New Life," the scarlet flowers being distinctly striped with white, the plant being of dwarf habit and a free bloomer. J. Tyerman, Esq., Penlu, Cornwall, had a vote of thanks for his *Groundsel*, a large single flower 2 inches in diameter and effective.

Henderson's seed pocket-filler was exhibited by Blake and Mackenzie, Liverpool. It is a very ingenious contrivance for filling seed pockets with any weight of seed required by the simple turn of a handle; it is, in fact, a labour-saving machine, likely to be of great use to retail seedsmen. Mr. Matthews, The Potteries, Weston-super-Mare, exhibited a plant-protector, which may be described as an earthenware seed pan minus its bot. cm. From the Society's garden at Chiswick came a branch of *Dan ia imperialis* laden with numerous striking single blush flowers. This is a seldom seen but most effective plant for winter decoration.

Gold medals from the Davis fund were recommended to be given to Messrs. Veitch & Sons, Mr. C. Turner, Mr. Wildsmith, Mr. Haycock, Mr. R. Dean, Mr. Wills, and Mr. Ford for the excellence of their collections.

### TROPEOLUM SPECIOSUM.

I AM very pleased to think this lovely plant has been noticed by two of your correspondents, and as it seems to have but slight acquaintances in the south I write a few observations respecting it.

My first acquaintance with it was at the Gardens, Holkham Hall, Norfolk, where it was grown under a north wall; a permanent 12-feet-high wire trellis being fixed, where it was allowed to climb without any pinching, and only an occasional tying to preserve neatness.

On the approach of fine spring weather it soon began to push up its somewhat delicate-looking shoots, and seldom failed, when the length of 2 or 3 feet had been gained, to throw out its charming scarlet flowers. To see a wall massed with it is simply to survey a gorgeous spectacle, the small dark green leaflets contrasting with and toning down the brilliant colour effectively. At Holkham it was the wonder of all who saw it. It kept in flower during a considerable part of summer, looking best during the autumn months, and continuing its beauty till the November frosts effectively blackened its gay appearance. The season's growth was afterwards cut back to its base, and the plant was allowed during winter to take its chance unprotected by any other covering than the soil it was planted in. It generally flowers much more freely on a north wall in the southern and midland counties than in a more sunny position, and though "A RAMBLER" does not mention explicitly its aspect in that lovely northern nook, yet we can guess what the effect would be in the romantic surroundings which pervade that part.

I trust that others may be induced to bring this plant under the notice of your readers, as it is truly well worthy a prominent position in every gardening establishment.—R. B.

### NOTES AND GLEANINGS.

We are very pleased to know that the Hon. and Rev. J. T. Boscawen purposes, at the centenary meeting of the Bath and West of England Society next year, asking the Council to allow him to offer two cups of the value of ten guineas each for the best twelve TEA ROSES, one cup to amateurs, the other to nurserymen. He will ask all the leading Rose-growers to join in a sweepstakes, each exhibitor paying an entrance fee, say 10s. or £1, the money to go with the cup. A second prize will also be given by the Society to enable prizetakers to pay expenses.

—MR. E. WILSON writes, "I find Veitch's RED GLOBE TURNIP to be a first-class sort—in fact the best I have grown

this season amongst three or four other kinds; for while White Dutch, Golden Ball, Chirk Castle, &c., were rendered keen and stringy by the very hot weather we had this last summer, Veitch's was mild and tender, which is a great consideration."

— THE FLORAL DECORATIONS AT THE GUILDHALL on the 9th inst. have been entrusted to Mr. John Wills. Nine hundred button-hole bouquets will be made-up by Mr. Wills for the occasion. The groups of plants employed in the decoration of the corridors, porticos, &c., will also be of the choicest character.

— WE have received from Messrs. Dick Radclyffe & Co. samples of TOUGHENED GLASS for horticultural structures and roof lights, and find it what it is represented—as being really tough and unbreakable by any fair means. The square which we tested was at least ten times stronger than ordinary glass of the same thickness. It was little more than one-sixteenth of an inch thick, and might be termed 16-oz. glass. When laid on the floor it was trampled upon by a person weighing 14 stones and bore the weight bravely. It was broken at last by a test far exceeding the force of any hailstones which we have observed. It is as clear as ordinary glass, but not quite smooth, being "wavy" and containing some lens. If the glass retains its extraordinary cohesion under the heat of summer and the frost of winter, and if the foliage under it does not scorch, the invention will prove of great value. The tile made of the same glass combines great strength with admission of light.

— WE recently saw a break of CARROTS in old kitchen-garden soil where for years they had been destroyed with worms, part of which was this year well watered, before the seed was sown, with water to every four gallons of which were added two wine-glassfuls of paraffin oil, and the portion of the break so watered was bearing a luxuriant crop of Carrots, while on the portion not watered they failed as usual.—(*Gardener.*)

— A VERY successful instance of GROWING GRAPES IN THE OPEN AIR is afforded in the gardens at Vinters Park near Maidstone. A Sweetwater Vine on an east aspect has this season ripened four hundred bunches of really excellent Grapes, which have been very serviceable and greatly esteemed for dessert purposes. To grow out-of-door Grapes successfully the same care in thinning the fruit and dressing the growth is necessary that Mr. Record has given to this Vine. When we saw it the wall was literally covered with well-finished bunches. It is passing strange that while so much attention is readily given to Vines under glass, those on walls are almost systematically neglected. By a selection of proper sorts and good cultural attention many having south walls might have Grapes equal to those which Mr. Record produces on an eastern exposure, and for which he received a cultural commendation last year from the Royal Horticultural Society. As to the management of out-of-door Vines Mr. Douglas gives sound instructions in another column.

— AT Muckross Abbey, the seat of H. A. Herbert, Esq., M.P., there are several specimens of CEDRUS DEODARA bearing cones. These are borne on the branches that come quite to the ground, continuing to within 3 feet of the top. They are not borne on the young wood, but are found on the upper side of the branches, growing perpendicularly, and not nearer than 12 inches to the outside of the branch, which leads Mr. Campbell, the gardener, to think that it is the old and matured wood that bears cones. The size of the cones are increasing rapidly. Some are  $2\frac{1}{2}$  inches in length by  $2\frac{3}{4}$  in circumference, but he doubts if they will perfect their seed.

— AT the Philadelphia Centennial Exhibition the show of POTATOES is described as exceedingly fine. Messrs. Bliss exhibit 387 varieties, including fifty fine English and five French seedlings; also a hundred new seedlings from Pringle's hybridised seed not yet in commerce. In the immense collection shown by Dr. Hexamer may be seen side by side the work of the past with the promise of the future. Every known variety of excellence both in Europe and in America is brought together, making in all five hundred named kinds.

— THE annual general meeting of the WEST OF SCOTLAND ROSARIANS' SOCIETY was held in the Town Hall, Helensburgh, on the 28th ult. The Society appears to be in a very satisfactory condition, the membership being considerably larger than that of last year, and after paying all accounts, including over £70 for prizes, there is still a balance left in the hands of the Treasurer. The office-bearers and Directors for the ensuing year were elected, and it was resolved that the next exhibition

of the Society should be held in Helensburgh on July 13th and 14th. Votes of thanks were awarded to the office-bearers and Directors for their services, also to Alexander Breingan, Esq., for the use of Westwood Park, gratuitously granted for the use of the Society. Mr. John Mitchell, Brooklee, is the Honorary Secretary.

— FOR producing a rich glow of brilliant scarlet flowers during the autumn months on walls and trellises the LOBBIANUM section of TROPEOLUM are well adapted. They are far more effective and floriferous than the common Nasturtiums, and grow with even greater freedom than these. We have to-day (November 6th) been admiring a variety of T. Lobbianum which is covering a wall having a due north aspect, and the effect is quite dazzling, while the Dahlias near are killed by the frost. Under glass these Tropæolums continue flowering throughout the winter, and are valuable in producing a supply of orange-scarlet flowers. The plants may be raised either from cuttings or seed.

— THE appointment of Mr. Frederick Moore, eldest son of Dr. Moore of Glasnevin, to the CURATORSHIP OF THE UNIVERSITY BOTANIC GARDEN, Ball's Bridge, is calculated both to give satisfaction to the governing body of the institution of which the garden is an appanage, and to enhance the teaching value of the latter to students and visitors. Mr. Moore is highly educated, and has had careful training both at home and on the Continent to fit him for filling this or a similar post. Mr. Moore has been perfecting himself in the practical part of his profession at the establishment of the late M. Van Houtte at Ghent and also at Leyden.

— THE next BATH MEETING of the Bath and West of England Agricultural Society is fixed to be held on the 4th of June, 1877.

— INSTEAD of finding VERONICA BLUE GEM indifferently grown in only a few gardens, we can only wonder that it is not well grown in all gardens. Where a profusion of blue flowers are required for cutting from the present time until January, this Veronica should certainly be grown. The plant is of compact yet pleasing habit, and its small glossy-green leaves set off the lovely-coloured flowers to great advantage. The plant is of the easiest culture—so easy that perhaps the best mode to adopt is to plant it out in good soil and an open situation in May, and pot it in October. We have recently seen plants 2 or 3 feet in diameter which have been so grown now perfectly established under glass, and, yielding large quantities of flowers much prized for bouquets and room decoration.

— A FINE companion plant to the valuable scarlet Geranium Vesuvius for winter flowering, is the rosy-salmon variety Mrs. G. SMITH. We have lately seen batches of these varieties which cannot fail to be of great value for a long time to come. They are throwing-up trusses as freely as in summer, and the brightness of one variety and the soft pleasing colour of the other produce an effect which none can pass without acknowledgment. Mrs. G. Smith is a perfectly-formed flower, and is a very desirable variety for cultivation in pots.

— WE have accounts from various districts of the spread of the POTATO DISEASE. Since the rains have abated and the temperature has fallen the disease has been checked so long as the tubers remained in the ground, but when stored at all thickly it has spread with considerable virulence. Especially since the disease has asserted itself the advice to "store dry, thin, and cool" cannot be repeated with too much emphasis, as the best means of modifying the effects of an unfortunate visitation.

— WE regret to announce the DEATH OF MR. EDWARD GEORGE HENDERSON of the Wellington Nursery, which took place on the 4th inst., in the ninety-fourth year of his age. Mr. Henderson was the founder of that important nursery, and was an energetic and successful horticulturist. On account of advancing age he had for some years prior to his death ceased taking an active part in the business, which will therefore be continued without any change in its management.

#### METROPOLITAN FLORAL SOCIETY.

IN his paper on Tulips in last week's Journal Mr. Douglas has made a statement with reference to this Society at which I am very much surprised, and which I take the earliest opportunity of correcting. He says that its members did not pull well together, and that hence nothing was done this year. I

can only say that I have never known any difference of opinion even amongst those who had to work it, save that Mr. Douglas himself, with a chivalry worthy of his name, thought we ought with an empty exchequer to have offered prizes and arranged for an autumn show this year. The truth is, we were from the very first dependant on the contributions of one of the great Companies—the Crystal Palace or Alexandra—for our existence, and when they both gave us up we had nothing to fall back upon. Autumn shows do not pay in London, and the Crystal Palace Company is obliged to add other attractions to make theirs pay. Florists' flowers seem hopelessly at a discount in the south.

Mr. Douglas alludes to the fine bank of Picotees and Carnations at the Royal Horticultural Society in July. There were fine flowers there according to the present notion, but there were just five exhibitors—three from the neighbourhood of London, one from Ipswich, and one from Bath—a very poor foundation on which to rest a hope of a revival of the taste. He speaks of the National Auricula Society coming to London. I should be delighted to see it hold its show there, but they will not come unless some society guarantees them £20, the same that the Manchester Botanical Society gives them, and I do not know where the money is to come from.—D., Deal.

### PLANTS SUITABLE FOR DINNER-TABLE DECORATION IN WINTER.

In the summer season when plenty of flowers can be gathered out of doors it is a simple matter to make the dinner table attractive, but for the next five or six months plants will have to be chiefly depended upon for table adornment. Many plants which are extremely ornamental and becoming on a table surrounded with flowers lose much of their beauty without them. These are mostly green-leaved plants; but there are others, again, which instead of cut flowers adding to their beauty they only detract from it. It is this latter class of plants which should be cultivated almost exclusively for winter table decoration. All plants for the dinner table should be as elegant in habit and as different in character as possible, because when one plant is placed very frequently on the table it appears to lose much of its attractiveness, and plants which are similar to one another are not likely to be fully appreciated. The following are enumerated as superior:—

*Dracenas*.—Some of these are amongst the best of plants both in habit and colour for placing singly on the centre of the table. Some excellent new varieties have been raised lately; and although many of them are well adapted for growing into specimens for exhibition purposes, I have not found any of them more useful for table decoration than the old *D. terminalis* and *D. terminalis stricta*. They are compact in habit, with elegant leaves; their colours are always bright and pleasing, the rich bright crimson being especially attractive in both natural and artificial light. *D. Chelsonii* I consider too dark in colour for our purpose, and the same might be said of *D. Mooreana* and one or two others. Indeed none of those of deep metallic hue are very showy on the table. All the *Dracenas* of the indivisa section are excellent plants for the table, as they are most elegant in habit, and they may be grown in a cooler place than most of the other sorts. *Dracenas* are easily multiplied by cutting up the stems into pieces about 2 inches long and covering them over with soil in a smart bottom heat any time during the winter. They may be laid closely together, and when the leaves are about 3 inches long the young plants should be potted singly into small pots, using a mixture of loam, peat, and silver sand, and shifting into larger pots as it becomes necessary. The leaves should be sponged frequently to keep them free from insects and dust.

*Pandanus Veitchii*.—This is the finest of all the Screw Pines, and undoubtedly the best for table decoration, both its form and colour being in its favour for this purpose. The leaves are splendidly striped with lines of deep green and pure white, and droop in a graceful manner. Plants for the table may be grown in 6-inch pots. I find the leaves are brightest in colour when the plants are grown amongst plenty of silver sand.

*Aralia Veitchii*.—In a small state this plant is exceedingly elegant in outline, its slender undulated leaves being of a beautiful dark glossy green. It is quite different in character from the preceding, and is a fine change from it on the table. It is propagated from cuttings and eyes, and thrives in a mixture of peat and silver sand.

*Abutilon Darwinii tessellatum*.—This is the finest marked of

all the *Abutilons*, and a plant which nearly everyone admires. Its habit is not quite perfect for the table, but its curious marking makes up for this slight deficiency. The leaves grow to a good size, and are beautifully marked all over with small squares of deep green and golden yellow, the latter appearing on the former like particles of inlaid wood. It is raised from cuttings, and grows freely, under greenhouse treatment, in a mixture of loam, leaf soil, and sand.

*Palms*.—*Cocos Weddelliana* and *Geonoma gracilis* are amongst the finest for table decoration. Both are alike elegant, only the latter droops a little more than the former, and is slightly paler in colour. Both require a stove temperature, and luxuriate in a mixture of peat and sand. There is nothing peculiar required in their treatment, and they may be grown successfully in any stove structure.

*Crotons*.—The best of these are *C. majesticum*, *C. picturatum*, *C. Johannis*, and *C. Youngii*. No other plants possess the same colour and habit as these, their long, narrow, green, yellow, and crimson leaves having a grand appearance. They are propagated from cuttings, which require a warm place and good attention to strike them, but when once rooted they grow freely amongst other stove plants, provided their pots are well drained and the roots have some good peat and silver sand to work amongst. They are rather subject to the attacks of insects, especially thrips and red spider, and to prevent these from doing harm the leaves must be frequently sponged and syringed.

*Ficus elastica*.—This is not by any means such a rare or even beautiful plant as any of the above, but it is easily grown, and on this account it may meet the wants of many; and at the same time it is not wholly destitute of ornament, as the dark, bright shining green leaves have a very massive appearance, and they have the advantage of remaining fresh in close rooms much longer than is good for most plants. It is only in a young state when the plants are from 12 to 18 inches high that they can be used on the table. I have propagated numbers of this plant without the assistance of bottom heat by simply making the eyes like Vine eyes and inserting them singly in small pots filled with a mixture of leaf soil and sand in about equal parts, and placing them in a close frame until they were rooted. These plants will grow in almost any kind of soil, and do not require a warmer place at any time than a greenhouse.

*Epiphyllums*.—Many of these are in perfection just now, and a succession of them will keep on flowering for the next few months to come. When well grown and bloomed no flowering plants are more lovely on the table. The best plants for this purpose are those with stems from 1 to 2 feet in height with drooping bushy heads. To have them in this form they must be grafted on the *Pereskia* or some other suitable stock. Plants "worked" now would be in good decorative condition two years hence. They delight in a rough soil such as fibrous loam, peat, silver sand, and small lumps of charcoal and broken pots or bricks. They do not require potting every year, and useful plants may be grown for a long time in 6-inch pots. They should be grown in a warm moist place, and removed into a cooler and drier situation when the growth is completed. They should be kept rather dry at the roots when the plants have ceased growing, but they must not be allowed to shrivel up for want of water. All insects, especially mealy bug, must be sponged-off, care being taken to clean it well out from the joints of the leaves. A few good varieties are *E. truncatum amabile*, white, upper part of the petals marked with purple; *E. truncatum cruentum*, dark purple; *E. truncatum roseum*, bright rose; and *E. truncatum coccineum*, deep scarlet.

*Spiraea japonica*.—Well-grown plants of this old Meadow-sweet when forced into flower in the winter time are well adapted for the table, the deep green leaves and pure white flowers being in excellent harmony. *Spiræas* delight in an open soil, with plenty of water at the roots while growing, and may be had in flower any time from November until April.

*Ferns*.—The old *Adiantum cuneatum*, and indeed most of the Maidenhair section, are suitable for the table. *A. gracilimum* is very neat, but not quite showy enough; but the opposite is the case with *A. Farleyense*, the fronds of which when fully developed have a rich appearance by artificial light. But, except for a change, I find *Ferns* are not in such demand for dinner-table decoration as fine showy foliage and flowering plants.

The above is by no means an exhaustive selection of table plants for the winter, but I have found all of them exceedingly useful, and those who possess them will have no difficulty

in finding a suitable plant for the table during the winter months.—J. M.

### NOTES ON ANNUALS.

For the last ten years I have devoted a great amount of attention to the growing of hardy and half-hardy annuals, generally sowing above one hundred kinds every year, principally as a test to prove which are the best and really worth growing, also to find out for what purposes the various sorts are best adapted; and it may be useful to readers of the Journal if I give my experience and name those kinds which invariably prove satisfactory.

As my method of treating half-hardy annuals is somewhat different from the instructions generally given, I will mention a few points I have found necessary to attend to. I select a perfectly open site, and do not sow until the end of April, and then only the hardiest sorts, deferring the sowing of those which are more tender from the 1st to the 10th of May. By sowing thus late the seedlings come up quickly, invariably escape the late spring frosts and biting east winds, and become strong healthy plants producing abundance of flowers, which last longer in bloom than the same kinds reared under glass and transplanted in the open ground. Another important point is the sowing. Many of the seeds are very small and are often covered too deep and never come up. I cover them very slightly with fine sifted soil, watering the beds thoroughly before sowing the seed, and never allow the plants to become crowded. If too thick I find the greater part will bear transplanting by choosing a dull or showery day. I append a list of the best annuals:—

*Half-hardy.*—French Aster, German Ten-week Stock, Phlox Drummondii, Zinnia elegans, double and single; Zinnia Haageana, double yellow; Mexican Zinnias, single deep orange; Tagetes pumila; Dianthus Heddewigii; Petunia Jacobæa, crimson, purple, and white; Sanvitalia procumbens, double; Marigolds, French and African, and brown and yellow ditto; and Salpiglossis, various, very beautiful.

The first twelve are well adapted for bedding; the fifth, sixth, and seventh are good substitutes for the Calceolaria; and on poor soil the first, second, third, fourth, and ninth are very effective in ribbon borders, while the greater part of them are good for cut flowers.

*Hardy.*—Scabious in variety, dwarf and tall; Larkspur, dwarf Hyacinth-flowered, and tall mixed double varieties; Linum, scarlet, Viscaria oculata, Saponaria calabrica, Eschscholtzia aurantiaca, Iberis hesperidifolia, Erysimum arkanianum, Godetia Lindleyana, double; Tom Thumb Nasturtiums, scarlet, and yellow; King Theodore, dark crimson; King of Tom Thumbs, brilliant crimson scarlet; Crystal Palace Gem, yellow and maroon; Whitlavia grandiflora and W. gloxinoides; Lupinus Menziesi, tricolor, hybridus, atrosanguineus, and nanus.

*For Scent.*—Mignonette and Mathiola bicornis, very fragrant in the evening; Sweet Peas, mixed; Helianthus californicus and H. globosus fistulosus. The two last are fine for the shrubbery.

[Some portion of the writer's notes are apparently missing, and he will oblige by supplying them.—EDS.]

### CHAPTERS ON INSECTS FOR GARDENERS.

No. 12.

A CERTAIN amount of wonderment has been expressed that, when the enormous number of exotic plants now cultivated in England is considered, the proportion of species of insects introduced with these is found to be so small. Even from those species which are generally reputed to be of foreign parentage a deduction must be made, for species which in all probability were really British, but kept themselves comparatively out of view until we took to cultivating largely some plant or shrub they prefer. Now, undoubtedly the fauna as well as the flora of a country like ours is capable of undergoing change; but in the majority of cases the naturalisation of a new species wants an amount of care and caution which no one scarcely would take with an insect; in fact all our efforts are put forth in the opposite direction. Then as to accidental introductions, it must be borne in mind that a great many of our new plants came to England in the seed state and as tubers or bulbs, when they would be less likely to be infested with insects than in a state of growth; or they have travelled here as small cuttings and slips, when they would naturally

receive an amount of attentive watching, probably fatal to an unwelcome visitant of the insect family. Moreover, our changeful and humid English winters and our cold springs are "as good as poison" to insects accustomed to the more equable climes, whence come some of our favourites of the garden or conservatory.

It would appear that it is in the group of scale insects that we have had most intrusive foreign pests, and this is to be accounted for from the habits of many of the Coccidæ, where the female clings closely to the branch or twig, her dried body forming a shield beneath which the young insects are nurtured just at the period when they would be otherwise in much danger of destruction from external causes; also by some gardeners these germs of insect life are apt to be overlooked until they have reached a period of their development when they are less easily dealt with. And in our stoves or forcing houses various species find they are quite as much at home as in the lands to which they more properly belong, having, if left alone, just those circumstances favourable to their increase. In short, if the Aphides may be deemed on the whole the most troublesome enemies the gardener has to contend with, the Coccidæ may be reckoned the most insidious.

Before entering on a description of the Monomera, the last subdivision of the bugs or Homoptera, under which are comprehended the two prolific species popularly called mealy bugs or "scales," it should be noted that the American blight stands in an intermediate place between the true aphides and the Coccidæ. This and species similar were once designated Pseudococci, as they have not the apparatus which drops honeydew, and in their cottony envelopment they resemble the family of the Coccidæ, though in other particulars of their habits they approach the Aphides. In the winter they do not generally die off as do the Aphides —(and just at this moment we have arrived at the season which Francis Walker calls the time of Aphis-fall, when, accompanying the dropping

Fig. 61.—Scale.

leaves, myriads upon myriads of these descend to the earth and die, leaving batches of eggs for the next spring)—but they either creep down towards the roots of the trees and hide partially under the soil, or they seek out crannies in the bark and there repose during the winter, covering themselves with their cottony down; and from this peculiar protection, evidently serving to keep them warm, as well as probably a means of warding off the attacks of some parasitic foes, Newman infers with show of reason that this woolly Aphis bearing the modern name of Lachnus (Aphis) lanigera came from a warmer region to us. Newman was the first to experiment with regard to the best modes of dealing with this wholesale destroyer of Apple trees, his conclusion being that there was nothing to surpass hot size, only the applications of it must be repeated from day to day. In the fruit-producing districts of Kent, near my residence, whitewash seems largely patronised as a preventive and remedy, and is used both for Apple and Pear trees, though the value of this application will not compare with that of good size. Waterton's plan was to stifle the insects by means of clay, and others have devised compounds of tar and strong-smelling oils, which may kill partially. But it is admitted that in large orchards little can be done, and people have to resort to the destruction of all infected branches or trees to check the spreading of this blight—a blight indeed, yet can no proof be adduced that it ought to be called American; and at our antipodes, where the colonists are much troubled with it, they might as justly style it the English blight, and declare that it was imported from these islands, as is possible. But if it did come from America we have taken our revenge by transmitting to them Coccus conchiformis, which, though comparatively harmless to our Apples, has proved a serious infliction across the water, only it is partly checked in its increase by a species of Acarus that preys upon it.—J. R. S. C.

### BATTERSEA PARK.

THIS noted park occupies 200 acres. It was purchased in 1851 by the Government for £11,000, and covers the space once occupied by the inn so celebrated for shooting matches,

and known as the Red House. It is famous for its sub-tropical garden, and occupies the foremost position in this style of gardening. There are several acres arranged to present a natural and picturesque effect. The whole is well shaded, and surrounded by groves of trees and handsome evergreen and flowering shrubs for the purpose of shelter. No one was better acquainted with their natural positions than Mr. John Gibson, who laid out this park, for he has seen most of the trees growing in their native country in far distant lands. The Palms, Tree Ferns, Bananas, Aralias, Dracenas, and other richly coloured leaves of plants growing out of the green turf, with hundreds of other subtropical rarities, brilliant in colour, graceful, and elegant in habit or leafage produce a charming effect. There are abundance of flowers of the most brilliant kinds, but everywhere relieved and set off by the green leaves of a diversified character. Another feature in the park is the

very beautiful in the autumn and winter months for general decorative purposes, and we have them in various colours, with larger trusses of bloom, ample foliage, and fringed flowers, yet the beauty of the singles is confined to the plant, while every pip of the doubles is available for cutting. Double Primulas have been grown for a long time, but propagated only from cuttings, which is a slow process, and one not conducive of vigour to the plants. Of late years, however, double varieties have been offered as coming true from seed. The seedlings were poor at first, but there is really now little to be wished for except in variety, and in this respect every year is bringing us additions.

The doubles are with me so much admired, and come so truly from seed, that I shall grow them extensively. I have from seed a grand lot of double white, double red (the old colour of *fimbriata rubra*), and also bright crimson (the colour

Fig. 62.—BATTERSEA PARK.

rockwork—a good imitation of nature, and vegetation is spreading well over the rugged parts. At the base are planted trailing and creeping plants, such as Sedums, Sempervivums, Saxifrages, Thymes, and other herbaceous and alpine plants too numerous to mention, the whole forming one of the gayest sights of the season.

There is also another class of plants extensively cultivated there—the ornamental Grasses, and which have a very decorative effect. The ornamental waters also form highly pleasing scenery. The Grasses are planted in and at the edge of the water, fringing the projecting parts with graceful drooping leaves and erect and noble inflorescence. *Arundo donax*, both green and variegated, is stately and graceful, being a vigorous and robust plant with long, broad, and recurved leaves. The variegated variety has broad silvery-striped leaves, as has the striped Japanese Maize (*Zea japonica*), which is free-growing and very ornamental, attaining the height of 6 feet. There are many others when planted in such situations that are exceedingly attractive, such as the *Erianthus ravenna* and the Pampas Grass. The details of this Park have been frequently noticed, and the ability of the Superintendent, Mr. Rogers, is generally admitted.—N. COLE, *Kensington Gardens*.

#### DOUBLE PRIMULAS FROM SEED.

THE double flowers are very much more valuable than the single from their greater endurance. The singles are, indeed,

of *kermesina splendens*), and a very fine double carmine, large and free. They are quite free in growth and flowering. The colour of the last is charming by candlelight, and its ample foliage and large trusses render it available for a dinner-table plant.—A.

#### JUDGING VEGETABLES.

I HAVE had excellent opportunities of seeing collections adjudicated upon, and have taken much interest in the decisions, and have also taken pains both in growing and exhibiting vegetables, yet I fail to see the force of Mr. Fairweather's argument—that Potatoes should stand first in order of merit simply because they are a staple article of food. The encouragement that the Potato has received at the Alexandra Palace does not in the slightest degree enhance its value when placed in a mixed collection of vegetables. The same number of dishes of Peas, Tomatoes, or even Vegetable Marrows were they collected in the same manner would be interesting, but their value would remain the same as before.

Were I asked what vegetable should be placed first in order of merit my reply would be, That variety which required most skill to produce it in perfection at a given time, and to possess such merit as to be most esteemed by employers at that time.

The value of different kinds of vegetables necessarily varies with the season. Had I to form a collection of twelve varieties during the month of June I should certainly try and include

good examples of Tomatoes and Vegetable Marrows, believing both would be appreciated by all judges; Peas I should place next, which should not be conspicuous for being old; Potatoes a good even sample not over-large, preferring white to red tubers; Cauliflowers white, close, and of moderate size. I have noticed more variations in judging Cauliflowers than any other vegetable, some judges giving preference to a small close Cauliflower, while others would appear to think that a Cauliflower cannot be too large so long as it is close and white. French Beans not in any way old, but of a fair size, indicating a quick and healthy growth; Globe Artichokes, Broad Beans, Cabbages of moderate size, young, close, and firm; Carrots of the Early Horn or intermediate section, smooth, straight, and of good colour; and Turnips medium in size, young, and quickly grown. Thus I have enumerated ten out of the twelve varieties required, all of which can be produced at the above-named season. The eleventh and twelfth may be chosen from Onions, Mushrooms, Asparagus (a good dish of which has great weight, but in some localities it would be going out of season, and consequently small). Lettuces and Cucumbers are auxiliaries. And in judging Cucumbers as a vegetable I contend that a large Cucumber, provided it is not yellow, ought to stand before a small and partly-developed fruit, for a Cucumber used as a vegetable is very different to a Cucumber used for a salad. The one is cooked in various ways; sometimes the seeds are scooped out and the fruit is cut in lengths, stuffed with forced meat, stewed and served in thick brown gravy, and the Cucumber is therefore required to be of fair size; whereas to be cut in slices and served with oil or vinegar it is imperative that the fruit should be young and not seedy, and ought to be judged accordingly. I have seen very good Celery also shown in June which in a collection should also carry some weight.

As leading to success it is very important that the schedule be made clear as to what is required of an exhibitor, and every stipulation should be plainly defined, for the judges have to be entirely guided by what is printed in the schedule. The schedule stating what is required, every exhibitor should aim at neatness and uniformity in arranging their respective collections, for taste in the arrangement of vegetables is quite as necessary as with any other exhibits. All roots, in my opinion, should be washed, and if dishes or plates are to be had the roots can be set up to advantage; and a collection of vegetables tastefully arranged is as attractive as anything else in the show. I have also seen vegetables attractively arranged in trays or in round baskets, and every article set off to the best advantage.

Now, as to the mode of judging the products staged. First see that the requisite number are set up, and then weigh over the merits of every dish in the collection by counting the number of points which it merits, taking three for the maximum and one as the minimum number of points. When this is carefully done I cannot think there can be much room for complaint.

Although at most exhibitions there will be found someone who feels himself aggrieved, all exhibitors should bear in mind that though their products may in their own eyes be perfection they may not be thought so highly of by a stranger.

In judging both amateurs' and cottagers' produce a disposition should be shown to give additional prizes to any vegetables of real merit, as such recognition often stimulates the exhibitors to further efforts, and brings about the desired effect for which cottagers' shows were originated.—A YOUNG HORTUS.

I AM not disposed to agree with Mr. Fairweather that Peas, Cauliflower, and Potatoes are to be put upon the same level with Cucumbers, Tomatoes, and Vegetable Marrows; the latter trio must in my opinion have the first place as the choicest varieties. Peas, Potatoes, and Cauliflowers—admitting their excellence—are common enough with every cottager, and in many cases are far better grown in cottage gardens than in gentlemen's gardens; but it is not the value or importance of either trio on a gentleman's table that we have to deal with, but the relative value the one bears to the other when placed in a collection for competition and judged by a practical man.

We all know the value of the Potato as a standard vegetable, and admit its great importance as an article of food and commerce, but he would be a bold man who could excuse himself to his employer for not growing Vegetable Marrows, Tomatoes, and Cucumbers because Peas, Potatoes, and Cauliflowers were of more value and importance on his table.

I was not aware until so informed by Mr. Fairweather that

there was any prevailing fashion in judging vegetables, but I well know that some judges hold very strange opinions, and make absurd awards in collections of vegetables; for instance, some three years since at one of the shows held annually in Scotland, one prize collection contained Red Cabbage, another Drumhead Cabbage and Savoy, and the third Savoy; while other collections containing superior examples of Cauliflower, Celery, &c., were overlooked. What says Mr. Fairweather to these decisions? Does he "or any other man" consider such things in season on the 1st of September?

Now for the cure. Let me suggest, as I have often done before, that in all collections of vegetables the varieties should be named in the schedule. This would prevent any difference of opinion with the judges, and their task would be an easy one, for quality must or should win. Exhibitors would then be able to form an opinion of the abilities of those appointed to decide upon the respective merits of their products.

One more suggestion—and that is, Let all judges use the knife freely. Where any doubt exists let them not decide in haste, because some collections are so well polished and otherwise prepared to gain the highest honours and most money. If, as it is customary to cut Melons to test their quality, and to taste Grapes and other fruits for flavour and ripeness, I maintain that it is as necessary and important to cut vegetables to arrive at a satisfactory decision.—CLEVELAND.

### OUR BORDER FLOWERS—VERATRUMS.

If we may credit dates the Veratrums found their way to our shores in 1596, we might have thought that they would be seen everywhere, but experience proves the contrary to be the fact. We may sometimes see a solitary plant, when it is regarded almost as a curiosity. Perhaps old Gerarde and others of his times were better acquainted with them than we are in these days of artistic gardening. The Veratrums are but a small family widely distributed.

They are a family of plants of sterling merit, and one cannot but regret that they are so generally neglected. They are not over-particular as to soil and situation, but the better they are treated the more beautiful they become. They may be made very effective in many ways and in many places both in and out of doors. They are excellent for vases on terrace walks, and are well adapted for exhibition; their splendid foliage and charming habit are conspicuous and attractive. They are well adapted for open spaces in the shrubbery. If well planted in deep and well-drained soil, composed of loam and vegetable matter, they will take care of themselves for a very long time. I know a place where some of them are planted out on a grassy slope and have taken care of themselves for more than twenty years, and they are greatly admired in late summer and autumn. They are increased by division in the spring when they are commencing their growth, or by seed sown as soon as ripe. The seed is a long time before it germinates, and should be kept in a cold pit or frame and protected from severe frost.

*Veratrum nigrum* is the species most commonly met with. *Veratrum album* is the plant that affords us the Hellebore powder that helps us to rid ourselves of the Gooseberry caterpillars. *V. viride* is a very desirable plant and ought to be in all gardens, for if not bright in colour there is something pleasing in its green flowers. When *V. nigrum* and *V. album* are contrasted together a very pleasing effect is produced. These plants if brought into more general cultivation would rival some of those subtropical subjects of which we hear so much, for the bold ribbed leaves of the Veratrums could not fail to place them in a high position among the beautiful-foliaged plants which are engaging attention at the present day.—VERITAS.

### NOTES ON VILLA AND SUBURBAN GARDENING.

FLOWER GARDEN.—After an unusually long and mild autumn frosts have at length arrived and destroyed all tender plants. *Heliotropes*, *Salvias*, *Dahlias*, *Alternantheras*, *Cannas*, and many others are killed to the ground, and flower gardens have now quite a shabby appearance. Those who grow spring-flowering plants should now clear the beds, dig and dress them, and have the spring flowers planted without delay. A few of the summer bedding plants, however, are not injured, and these may remain for some time longer. Such plants as *Sedum aureum variegatum*, *Golden Feather*, *Mesembryanthemums*, *Lencophyton Brownii*, and some others still look fresh and cheerful, and are among the best of our late bedding plants. Golden Chickweed has lost its

colour for the past two months, and is not to be depended upon as a general decorative bedding plant. Like the Golden Thyme it is in some districts green over half the year, and is not suitable for the purpose for which it was intended. We have some large scarlet Geraniums trained to a wall every summer, and they flower so satisfactorily that they are to be recommended especially for the purpose. These have all been taken up carefully and with as much ball as possible, and taken to a light open shed placed on the floor and surrounded with dry leaf soil. Here they remain till the spring, but they lose every leaf during winter; but they are induced to do so gradually by being sprinkled overhead every day or two, and the leaves as they die are kept cleared off. In the spring, just as they begin to break their buds and make a little root in the soil, the plants are put into such sized pots as will just accommodate their roots; the plants are then staked, and are ready for transferring to a more suitable place. This is not a glass house, however, but a temporary erection of thatched hurdles, high enough to shelter the plants, yet not so high as to shade them from the sun. The tops of the hurdles are not thatched, but a covering of mats are put over the plants every night. The front hurdle is moveable, so that the plants can be reached for any purpose. This mode of keeping such Geraniums may be as useful to some others as it is to me.

**TAKING-UP DAHLIAS.**—These have been cut down to within a foot or so of the ground, and if the roots are covered with fern or any other litter they will keep alive all the winter. I do not advise that mode of keeping them, especially for choice sorts, for I find that they break very weakly in the spring, and if they flower a little earlier it is at a time when flowers are plentiful and when Dahlias are not required. The safest plan is to take up the roots and pack them in dry soil or sand in a place where frost cannot reach them. Great care should be taken that the tubers are not bruised, and they ought to be moderately dry before storing away, and afterwards not allowed to have much moisture. I usually plant them out again in April after the soil has been manured and trenched. *Salvia patens* I treat in a similar way during winter and spring only, and to prevent the tubers shrivelling they are stored in rather moist soil.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

WE have often called attention to the necessity of pruning fruit trees during the summer and autumn months, especially those subjected to training, but we also find time to prune the standard Apple and Pear trees. At the same time it is necessary to look over all the trees at this season or during winter as time can be spared. Some gardeners do but little to their fruit trees during summer, and depend almost entirely upon the winter season for pruning. It will be best to take advantage of all this fine weather for pruning and nailing the wall fruit, for during frosty or wet cold weather other work that will not be so trying to the constitution may be proceeded with. We prune all the hardiest trees first, such as Apples, Pears, Plums, and Cherries, reserving Apricots, Peaches, and Nectarines until the last. A not uncommon mistake in pruning and training wall trees is to lay-in the wood too closely; but it is not enough to thin it now. This ought to have been done during the growing season, so that the wood and fruit buds would be fully exposed to the light, and air would be freely admitted to the trees. It is a sign of unskilful culture when the older wall trees become bare along the main branches. The young wood must be trained in such a manner that these are hidden as much as possible by it; and this skilful manipulation of the young wood will cause the trees to be regularly furnished with fruit all over the wall, instead of only bearing at the ends of the younger branches. The lower portion of the wall is also very often bare of healthy fruit-bearing wood; especially is this to be noticed on Peach and Nectarine trees, and always worst on those trees that have not made much healthy young wood. The only plan is to bring the main branches down nearer the surface of the ground. There is always plenty of wood to fill up the centre of the trees.

**Out-of-door Grape Vines** may now be pruned and trained. In the neighbourhood of London Black Hamburgh Grapes ripen well on walls in fine seasons, and the Royal Muscadine may invariably be depended upon to produce a crop. The Black Cluster is also well adapted for wall culture in the open air. We have seen excellent crops of Grapes on walls not more than 5 feet in height, forming the division lines between small villa gardens. The best method of training is to conduct a shoot right and left from the main stem in a horizontal direction along the base of the wall about a foot from the surface of the ground, and from these horizontal rods train upright growths about 2 feet apart. These ought to be renewed every second or third year. This method of training is not often pursued, but it is the best, not only for obtaining a good supply of fruit of the best quality, but also for the appearance of the walls. Old

scrubby canes never produce large bunches, and such varieties as Royal Muscadine and White Sweetwater fail to produce any bunches when the wood becomes old and the spurs are closely cut in.

Fruit borders may be dug after the leaves have fallen and the trees have been looked over to remove any wood not required for next season. See that all planting is done as soon as possible according to previous directions.

### PINE HOUSES.

The work required in this department varies but little from week to week at this season of the year. The temperature of the house where fruit is ripening is maintained by night at 65°. Houses where the plants are at rest are kept 10° lower; very little water is required at the roots of the plants, and no water should be kept in the steam troughs. When the days are fine with a good deal of sunshine and the nights frosty the air becomes dry, and moisture may then be supplied by damping the paths and walls of the house early in the forenoon. All other work is the same as that detailed in previous weeks.

**Orange Trees in Pots.**—Some of the Oranges have begun to change colour, others are not more than half the size they will yet attain, and are quite green. A temperature of 65° is necessary for them, and the leaves as well as the branches must be kept clean by handwashing with soapy water. Orange trees require generous treatment in order to produce full-sized fruit of good flavour. In addition to the substantial turfy loam in which the trees are potted they require to be surface-dressed with guano or blood manure when the pots have become filled with roots, but such concentrated stimulants require to be mixed with an equal proportion of loam and pounded charcoal, and a handful of this applied to the surface of the pots occasionally causes the leaves, if they were of a pale green previously, to become of a dark glossy green. The Tangerine is the earliest, and we have had fruit of this variety in November and December of the best possible flavour, and twice as large as the best foreign specimens sold in Covent Garden Market. St. Michael's and Maltese Blood have given us good fruit as late as April. The fruit hangs a long time after it is ready to gather, but it loses flavour when over-ripe.

### CUCUMBER HOUSE.

We put the plants out this autumn in a much less quantity of compost than usual, and we find they succeed best when there is not a large body of soil. When visiting at Hardwicke Hall last winter I was particularly struck with the small quantity of soil Mr. Fish used both for Melons and Cucumbers. The soil was, I believe, not more than a few inches in depth and laid on a slate platform, which also served the purpose of a stage for plants during the winter season. We train the shoots a few inches nearer the glass in winter, but the trellis is made moveable, and can be raised or lowered at pleasure. Cucumber plants ought to be grown in a rather moist atmosphere, and the temperature ought not to fall below 65° at night, and as much air should be admitted by day as possible. Unless the leaves are thick and firm in texture good Cucumbers will not be produced, nor will the plants continue long in good health. Red spider must be kept from the leaves by syringing them thoroughly on fine mornings. The water must be applied with considerable force, but the work must not be done by inexperienced hands, else the leaves, which are very fragile, might be torn into shreds by the force of the water. On the first appearance of mildew dust the affected parts with dry sulphur. Thrips do much damage and are very difficult to destroy, but nothing is more effectual than fumigating with tobacco smoke.

### GREENHOUSE AND CONSERVATORY.

These structures are now gay with *Chrysanthemums* of sorts, and these will continue producing flowers until after Christmas. More than any other class of florists' flowers the *Chrysanthemum* contains varieties that bloom very early and others very late, and each class contains such flowers that open at different stages. Take, for instance, the Chinese or large-flowering section. One of the earliest to open is the beautiful clear yellow *Gloria Mundi*, the bright crimson *Dr. Sharp*, followed by the pure white incurved *Mrs. G. Rundle* and the primrose and golden sports from it. *Empress of India*, white; *Guernsey Nugget*, primrose; *Jardin des Plantes*, golden; *Queen of England*, and sports from it, are all among the early flowers. Those to open about three weeks later than the earliest of the above are *Lady Slade*, *Princess of Wales*, *Princess of Teck*, *Venus*, *Pink Perfection*, *Lady Hardinge*, and *Isabella Bott*. In the *Pompon* section we have the same results. Some of the earliest are *Cedo Nulli* and its golden, lilac, and brown varieties. *James Forsyth* and *White Travenna* are early, followed by *Andromeda*, *Mrs. Dix*, *Golden Anrore*, *Mdlle. Martha*, very large pure white; *Bob*, *Brilliant*, and *Antonius*. There are also large-flowered *Anemones* and *Anemone Pompons* which contain very fine flowers. The best large-flowered are *Louis Bonamy*, lilac; *Fleur de Marie*, pure white; *Lady Margaret*, white; *Gluck*, yellow; *Empress*, large lilac; *Mrs. Pethers*, rosy lilac; *King of Anemones*, the most perfect-formed flower. *Anemone Pompons* are *Madame Montels*; *Miss Nightingale*, bluish; *Antonius*,

best yellow; Firefly, scarlet; *Astrea*, lilac; and Jean Hinchette, late white. Japanese sorts are now well known to be very fine and distinct decorative plants. The earliest and best flower is Elaine, pure white, the petals stained at the back with red. James Salter is a fine flower, opening about the same time. These are succeeded by Fair Maid of Guernsey, Apollo, Garnet, Prince Satsuma, Jane Salter, Red Dragon, Hero of Magdala, Dr. Masters, Erecta Superba, and Magnum Bonum. Every flower named in the above list might be grown in a select collection.

Perpetual-flowering Carnations are now coming into flower, and our couple of dozens of plants will furnish blooms all through the winter months. The flowers are near the glass in a cool greenhouse. Some of the ordinary florist type of Carnations promised to run to flower a few weeks ago, and were also removed to the greenhouse. We have not cut blooms from this section at Christmas; but Mr. G. Budd of Undercliffe, Bradford, an ardent amateur cultivator, told us that he cut a bunch of very fine blooms at that festive season last year from plants placed in his greenhouse. Cyclamens are also making very fine healthy growth in the greenhouse. We have put the plants near the glass, and are very careful in watering them not to wet the centre of the mass of leaves and flower buds.

*Primula sinensis* in all the varieties requires a shelf near the glass, and the plants like a higher temperature than is desirable for most other greenhouse plants. We find them damp off at the neck if they are at a great distance from the glass and in a low temperature. On the first appearance of decay at the collar of the plants we dust the affected parts with dry lime. It is no use trying to grow the double-flowered varieties unless the plants are close to the glass and in a dry airy house.

Attention has frequently been directed to mildew on New Holland and other hardwooded plants. Particular attention must be devoted to them at this season, and on the first appearance of the parasite dust the affected parts with dry sulphur. All plants must be kept perfectly free from insect pests. Fumigating with tobacco smoke as a preventive is highly necessary at this season. Red spider can generally be removed, from small plants at least, with a sponge and soapy water.—J. DOUGLAS.

### TRADE CATALOGUES RECEIVED.

Simon-Louis Brothers, à Plantières, near Metz.—*Catalogue of Fruit and Ornamental Trees.*

Vilmorin-Andrieux et Cie, 4, Quai de la Mesagerie, Paris.—*Catalogue of Bulbous-rooted Plants.*

Jean Nuytens Verschaffelt, No. 134, Faubourg de Bruxelles, Ghent, Belgium.—*General Plant Catalogue.*

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

SOUTH BERMONDSEY (Chrysanthemums). November 18th and 14th. Mr. D. Jewiss, Rosedale Arms, Rosebury Street, Bermondsey, Sec.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

WIMBLEDON (Chrysanthemums). November 15th and 16th. Mr. P. Appleby, 5, Linden Cottages, Hon. Sec.

BREXTON HILL (Chrysanthemums). November 17th and 18th. Mr. G. Goldfinch, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

BIRMINGHAM. November 22nd and 23rd. Mr. J. Hughes, Monument Place, Parker Street, Edgbaston, Sec.

ISLE OF THANET. August 30th, 1877. Mr. C. D. Smith, Hon. Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (J. Stuckey).—Brown's "Forester" and Sutton's "Permanent Pastures." The last you can have from Messrs. Sutton, nurserymen, Reading.

ADDRESS (J. W.).—Write to Mr. Boothby, Louth, Lincolnshire.

ROSE CULTURE (E. B.).—"The Garden Manual," free by post if twenty postage stamps are enclosed.

CHARGE FOR JOURNAL OF HORTICULTURE (Sammy).—For three months 3s. 9d., and for six months 7s. 6d.

JUDGING VEGETABLES.—We must decline inserting any more communications on the subject.

RASPBERRIES (*Chard*).—The three red varieties we recommend to you are Prince of Wales and Eastloft for heavy soil, and Red Antwerp for light soil. The culture is given fully in our "Fruit Manual," which you can have free by post if you enclose five postage stamps.

DRAIN PIPE CHOKED (H. T.).—It is not a weed, but the roots of some tree or plant that find an entrance through the joints of the pipe.

BLETIA TANKERVILLIÆ (R. S. P.).—It is a native of China, and a portrait of it is plate 1924 of the "Botanical Magazine." It is a stove Orchid, and requires no special culture.

PRIMULAS "BLIND" (*An Amateur*).—We have never noticed such a thing as Primulas showing fine trusses of flowers which prove blind. Probably you have not allowed time for the expansion of the flowers. Send us a specimen.

RAISING CARNATIONS FROM SEED (J. S. Webb).—The seed of Carnations may be sown in March in a pot or pan well drained, and filled to within half an inch of the rim with a compost of turfy loam three parts and one part of leaf soil, making the surface smooth, sifting a portion of the soil for that purpose and for covering the seed. Scatter the seed evenly and rather thinly, and cover with fine soil about an eighth of an inch deep. Place in a gentle hotbed, and water so as to keep the soil moist. When the plants appear keep them near the glass and admit air freely. When the second leaves have formed the plants may be removed to a cold frame, and after being well hardened-off be planted out in moderately rich soil in an open situation in rows a foot apart, and that distance from plant to plant. If room be a consideration the seedlings may be pricked off in rows 6 inches apart and 3 inches asunder, replanting them at the distances above named in September for blooming.

RAISING PYRETHRUMS FROM SEED (*Idem*).—Sow in pots or pans early in March in light moderately rich soil, just covering the seed with fine soil, placing the pans in gentle heat. The plants will appear in a few days, and should be kept near the glass and well aired. When two or three leaves besides the seed leaves are produced prick the plants off in pans or boxes about an inch apart, placing them in a frame, keeping rather close and shaded for a few days, then admitting air freely. By bedding-out time they will be good plants.

WINTERING GERANIUMS (*Lady Subscriber*).—Provided frost be excluded from the granary the plants will winter safely. We should not give water except to keep the stems and shoots from shrivelling, and if the pots were surrounded with hay or plunged in cocoa refuse, and the tops in severe weather covered with dry straw, it is likely you would keep the plants safely, and yet all depends upon keeping dry and excluding frost. The plants will need to be watered as they begin growing in spring.

RETARDING CAULIFLOWERS (W. S.).—The best plan would be to place the heads with a goodly amount of leaves in a basket or box upon the ice in an ice house, covering them with straw; but as you may not have an ice house, the only other plan we know is to cut the Cauliflowers with all the leaves attached and hang them in a shed, cellar, or other cool moist place. If decay when wanted place in water for a time until the heads recover their freshness.

PLANTING ROSES (*Would-be Rosarian*).—You could not have better distances than 4 feet for the rows, with the plants 2 feet apart, for growing Roses for cutting; but old plants will be of little use for affording exhibition blooms. Change them at least biennially. Manetti stocks to bud next season may be in rows 2 feet apart, and 9 inches apart in the rows, and the seedling Briars the same distance. Every other row to be removed after growing a year from the bud, and every two plants, leaving the third one in every other row for permanent growth. Manetti cuttings may be put-in in rows a foot apart and 6 inches asunder, omitting every fifth row for facility of weeding. Leave the Roses in rows 4 feet apart and 2 feet in the rows, as they are for at least another season, and if too thick take out every other, planting in their place two or three stocks of Manetti, which after growing a year from the bud may be disposed of. The other plants will give you blooms available for cutting for many years. The Manetti budded this year will require to make a year's growth before they can be disposed of, and should remain where they are.

VINES IN GREENHOUSE (J. S. S.).—We see no reason why Vines should not succeed in your house. Ferns do remarkably well under the shade of Vines. Wires would be required for the roof, and these ought to be strained tightly, not less than a foot from the glass; 15 inches is a better distance. The plant sent is a *Kalosanthes*. There are about a dozen varieties in cultivation. It is a greenhouse plant, and should be potted in sandy loam with a little leaf soil added. It likes a sunny position, and should not receive much water during the winter months.

CULTURE OF CARNATIONS (*Idem*).—To produce the finest blooms of Carnations and Picotees the plants ought to be grown in pots; but some of the more vigorous sorts succeed well out of doors; they do not require protection during winter. You ought to have layered the grass in August, and potted-off the young plants about the last week in September or early in October.

TOP-DRESSING VINE BORDERS (G. Smithers).—Your treatment so far is right, and seems to have been successful. Add one barrowload of decayed manure and a peck of crushed bones to eight barrowloads of your turfy loam.

SOLANUM CAPSICASTRUM (*Idem*).—You should place the plants now in a sunny position near the glass, and the night temperature should be about 55°. The lifting of the plants from the open border and potting them would have a tendency to cause the blooms to fall off without setting. They might not have dropped had you lifted them two or three weeks earlier.

DAHLIA FLOWERS SINGLE (*Novice*).—This is a not unfrequent occurrence, and we have seen it happen with the best cultivators. You must not propagate from such plants, or you will perpetuate a class of single flowers. It leaves a blank in the bud or border to remove the plants when the single blooms are observed. If they are allowed to remain until the end of the season the roots must then be destroyed. You can do nothing to prevent a few plants going wrong annually. We are not aware that single flowers have been more common than usual this year.

LOMBARDY POPLAR IN FLOWER BORDER (W. Stephenson).—The Roses and flowering plants may not as yet be much injured by the Poplars, but their heads and roots will injure them in a short time, therefore we advise the removal of the trees at once, taking them up by the roots. It is likely, however, that the trees may be of far more importance as a screen than the flowers, in which case you will, of course, sacrifice the flowers for the trees, but as to that you must determine.

VARIOUS (A. T.).—We cannot identify from a leaf, send us a flower. We publish "The Stove Manual." The worm is probably one of the wireworms.

Lime water is made with a peck of lime to forty gallons of water. It will not kill wireworms, nor would gas lime, nor would paraffin unless applied in quantities that would kill the plants also. Stirring the soil and picking-out the vermin is the only mode of conquering them.

**PLACING FLAGSTONES UNDER FRUIT TREES** (*St. Brigit*).—There is nothing gained by this practice. When the roots reach the outer edge of the stones they will work downwards.

**BEST TWELVE DARK CRIMSON ROSES** (*Idem*).—Abbé Brametel, Baron Chaurand, Black Prince, Charles Lefebvre, Duke of Edinburgh, Ferdinand de Lesseps, Firebrand, Fisher Holmes, Horace Vernet, Louis Van Houtte, Pierre Notting, and Prince Camille de Rohan.

**CELERY IMPERFECT** (*C. R.*).—If you sow the seed early and grow the plants well they will form good hearts. We suspect that your Celery is small and imperfect.

**INSECTS** (*J. W.*).—The caterpillar which on being handled has raised lumps between the fingers is the hairy larva of the Fox Moth (*Gastropacha rubi*). Several other similar caterpillars have the same injurious property.—*L. O. W.*

**NAMES OF FRUITS** (*A Novice*).—We cannot name your Grape from such a specimen. (*J. W.*).—1, Baronne de Mello; 2, Figue d'Alençon; 3, Comte de Flandres; 4, Hayshe's Prince of Wales; 5, Doyenné du Comice; 6, Triomphe de Jodoigne.

**NAMES OF PLANTS** (*J. H.*).—*Lunaria biennis*, Honesty. (*W. Denman*).—We cannot identify plants without seeing their flowers.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LES BASSES-COURS D'ANGLETERRE.

#### CHAPTER X.—STOKE PARK, IPSWICH.

IN our twenty-second volume, on pages 225 and 264, we find an account of the above yards with two illustrations. The account of them there is so graphic, and the hints, many of them, so valuable, that we are quite unable to improve upon them. Still our chapters on the poultry yards of England would never be complete unless we had a few lines about so famous an establishment as that at Stoke Park.

Since we were last there the yards have been greatly extended, and many new sheds and houses built, and really the new buildings are splendid for the purpose, being large and well built, looking as capable of housing a flock of cattle as a flock of fowls. The breeds which Lady Gwydyr now exhibits are Cochins of all colours and Dark and Light Brahmas. Mr. F. Wragg, who is still managing this large establishment with as much success as ever, seems peculiarly at home with the Asiatics. In the illustration of the egg-room, which is to be found on page 264 in the twenty-second volume, we find labels with Black and other coloured Hamburgs, Ducks, Silkies, &c., upon them, but we saw none of these breeds upon the premises in October last. We much regret that the breeding of Silkies has been discontinued, for Lady Gwydyr had for many years been a successful exhibitor of this quaint little breed. In other respects the arrangements seemed identical with the former description. One thing is peculiarly observable at Stoke Park—namely, the perfect cleanliness and order of everything. One might imagine that with so many houses, so many runs, and so much to look after, some things would be neglected; but it is not so, and cleanly raked yards, well-filled dust baths, and pure water are to be found in every compartment.

When we paid our last visit the stock birds and adults were, from the season, naturally much out of feather, but the immense size and wonderful healthiness of all the specimens was very conspicuous. Among the adults one Partridge cock especially took our attention. He was in good feather and simply gigantic. Perhaps he was a little too dark for some judges' taste, but no one could but observe his beautiful symmetry and wonderful size. An adult Dark Brahma cock or two we thought very highly of, for they were just such birds as we should like to breed from. Others there were quite as good, but a little too full in hocks for our taste; but the number was so great, and many had such diversity of feathering, that the most fastidious could but select one to his liking. As we passed from pen to pen and yard to yard we could but again and again notice the great cleanliness, and consequently were not surprised to find no birds in the hospital or on the sick list.

The manager has bred an immense number of chickens this year, and a very fine lot many of them are. They seemed quite unnumerable, and flocked about in the fields and under the shade of the hedges and cover in perfect troops. Of them all we thought the Black Cochins and Buff pullets were the most superior, though we saw a Dark Brahma cockerel or two of great promise. The new runs which have been made are not so much wired-in enclosures, but are good-sized sheds erected in corners of the park, where the inmates can have perfect liberty and go in for shelter from the heat or rain at pleasure. We can well believe chickens from this yard turn out good stock birds, for in their youth while growing they have perfect liberty over an unlimited range of grass land and a constant supply of wholesome food always at hand. Honestly fed and honestly grown do these chickens appear to be without the use of spices and condiments and other ingenious compounds. We noticed in most of the

chicken runs long wooden troughs filled with well-mixed soft food, so that the birds could always have a supply by them. With birds enjoying such unrestricted liberty this may doubtless answer, but we would not recommend those with but limited space to try it, or the birds would probably get dainty and lose their appetites.

The Buff pullets were in the shrubbery run just above the great shed used as a chicken nursery. There were about forty of them, and we doubt if we ever saw a more beautiful sight connected with poultry as this flock of birds exhibited. Perfect in colour, neat in heads, well-fluffed and leg-feathered, large, grandly shaped and symmetrical, each one seemed the counterpart of the other; and whether Lady Gwydyr exhibits them herself or disposes of them to her numerous applicants, we venture to feel sure that they will make their mark at the top of many good prize lists. The old hens were in such a deep state of moult that we could not criticise them, and we can only say here, as we did there, they must have the quality somewhere about them, as their offspring show it. We did not think so much of the Buff cockerels, though one or two were very promising; but they were, we were told, own brothers to the pullets we have described. We hope separate pens for breeding cockerels and pullets are not going to be made requisite in this breed. Certainly the cockerels were then very raw and unfurnished, and may have by now become more worthy of accompanying their handsome sisters. The Partridge and White Cochins seemed later; but we remarked one or two White cockerels of much promise, and we shall welcome their arrival in the show pens, for they are badly wanted this year. The Blacks had splendid bloom, their plumage was like Mr. Serjeantson's Black Hamburgs for metallic lustre, and we can full well believe the wide grass runs under the large trees help to keep them in such fine condition.

This, then, is a brief outline of what we found at Stoke Park in October, 1876. As we said, we have not attempted to describe the runs and yards, for it has been well done only five years ago. We have consequently but tried to describe faintly a few of the treasures which we found under Mr. Wragg's protection upon this occasion. We would recommend all to go and see this great establishment when in the vicinity, for they will be amply repaid for any trouble, and will find the manager ready to show them his stock and turn them into Brahma or Cochins fanciers.—*W.*

### KEEPING POULTRY.

If they are confined to house and run they must be supplied with every requisite inside the enclosure. A box of broken oyster shells must be always acceptable. I have often noticed fowls, when confined during the forepart of the day and let out towards evening, run first for the broken shells lying on the road, and afterwards for green and other dainties.

A box of fine gravel to each run is required as well as oyster shells. It helps to grind up the shell for lime to make eggshell, besides helps to digest the food. No fowl remains long in health without it, as its digestion would not be in its natural working order.

Another thing, the dust box must be always at hand and dry, or parasites will always overrun any house and fowls that are not thoroughly cleansed. Many a fancier calms his conscience on this matter by not making a good use of his eyes, there being a greater number of these pests than most people have any idea of, and a wide field awaits the patient observer to discover and bring them out. The several varieties differ very much in habit and appearance. Some live on the feathers, others on the body, others on chicks' heads, while some keep in the perches, nests, and woodwork of the house.

When confined, their food must be more varied than that of fowls running at large. Ground beef scraps are very good, they contain many small patches of bone. They will keep through the hottest weather, if they are kept dry. Poultry are very fond of this kind of food, and I prefer it to pork scraps. When this is not furnished, give them some ground bone at times, or what is better, hang up a small hopper on the wall, a little distance from the floor, that they may take what they like.

Always keep on hand sulphur, disinfectant powder, or carbolate of lime, and such things as will be likely to be used at any time, so that when occasion requires, or you have a little time to spare, you may not have to wait for them.

The test that calls for the use of disinfectants, more ventilation, or cleansing, is to go into the house any night after it is closed up, and if you observe an offensive odour you may depend that something more is requisite to keep the fowls in healthy condition. It is good to fumigate once or twice a month during winter. Now and then dust a little carbolate of lime about the walls and floor of the house while the birds are penned in it.

In wet weather see that your fowls do not get too much drenched. If a cold rain continues till night, do not let the birds roost on the trees that night (if they are in the habit of doing so), but drive them into the house, even if it be at the expense of getting a little wet yourself.

Most fowls know enough to go in themselves; but there is, and always will be, of fowls (as of other two-legged creatures), some so simple as not to know how to take care of themselves.—(*Rural New Yorker.*)

### CAN A POULTRY FARM PAY?—No. 2.

In my former article (page 293) I gave my reasons why I thought a poultry farm should pay in Great Britain. In the present sketch I purpose explaining how my friend and self intend managing our poultry farm.

1st, We are seeking for thirty acres of land at a moderate rental to commence operations. We have two good markets easy of access, besides a good chance of local sales.

2nd, We intend to take up both branches—viz., egg-producing and meat-producing, our breeding stock consisting of two hundred hens, all hardy good layers and good table birds, supplemented by fifty sitting hens, divided as under—sixty Houdans, sixty Brahmas, eighty Redcaps (and fifty Cochins are the best of mothers). All these are good layers—the Cochins are the best of mothers and sitters, the Houdans are nearly equal to Dorkings, and the Brahma cross with Houdans give fine birds for table. The Redcaps, again (not generally known), are considered in Yorkshire among the best layers, as well as plump good table birds, very hardy, and easily reared.

3rd, The system to be adopted is in the main the Bellair (French) one—namely, houses 16 feet by 15 feet, only instead of putting 330 hens into one house (which we shall do in the case of our young birds waiting for market), in our two producing-houses we shall put one hundred hens a-piece, divided as follows:—House 1, Twenty Brahma hens, twenty Houdans, and sixty Redcaps, with Brahma cocks. House 2, Twenty Redcap hens, forty Houdans, and forty Brahmas, with Houdan cocks. The fifty Cochins (mated when required with Houdans), will be kept in a spare shed, their duty being hatching young broods; still at other times they could be doing ordinary duty.

In this department, the hatching, the Brahmas could do good service also, leaving the egg-laying chiefly to the Houdans and Redcaps. It will be seen from this that we shall save complication of breeds and general arrangements, requiring only two large runs besides the breeding one for young chickens.

Next to a cottage opening from the kitchen is the breeding house, arranged much as the Bellair one, 16 feet by 15 feet. Houses 1, 2, stock houses, and same size. House 4 same size, with a supplementary house No. 5, 14 feet by 15, for young stock waiting for market. The supplementary house could hold 250 birds; say 580 in the two. On the other side of the yard will be a second breeding house, a house for Geese, one for Ducks, each as above, 15 by 16 feet, and a larger spare house 24 feet by 15; to this must be added store-room and packing room, each 16 feet by 15.

Between the chickens and the Waterfowl is a courtyard 45 feet by 28, open, if required, to both departments. The whole area, exclusive of cottage and store-rooms, is 60 feet square. We purpose keeping twenty Ducks—viz., ten Rouen and ten Aylesbury, as well as six Geese (Toulouse). Such, then, is our proposed stock, buildings, arrangements, and general plan of work; now for some of the minutiae.

First, I would call your attention to a proposed improvement of my own in the arrangement of nests, &c., in the fowl houses. According to the Bellair system the nests are placed in tiers one above another at each end of the houses, with roosting perches covering the centre area. According to my plan all the nests are on the ground, with board and perches as recommended by *The Canada Farmer*. These nests go all round the several houses; but as this would not give sufficient nests I multiply two double rows up the centre of each house, with boards and perches all the same height from the ground. These centre rows of nests are portable.

We do not expect to do all this producing power at once; we may begin with a half or a quarter of the stock as may hereafter be determined on. Again, we do not intend to keep our young stock on hand longer than to fit them for the market. We hope to arrange to send to the markets weekly or fortnightly all birds fit for table, and so to keep down the stock, thus having about five hundred birds fitting for market, a sufficient supply of young chicks in the breeding ground, and the breeding stock as above enumerated, thus having at most a thousand birds at one time throughout the year. In our estimates in the appendix a larger number is allowed for in calculating supply of food, &c. By the arrangement of our two producing-houses that while we get the double cross of Houdans and Brahmas, we have in each Brahma hens mated with Brahma cocks, and Houdan hens with Houdan cocks, so that the several breeds can with care and attention be kept pure, and enable us for some few years to renew the stock of pure-bred ones of each class.

In the house-arrangement and accommodation simplicity and economy have been duly cared for; the same may be said of the outside arrangement. We only require three divisions of runs—viz., one for breeding young chicks, one for the Houdan

cross, and one for the Brahma cross. The outside bounds of these runs to be constantly changed to suit rotation of crops; in fact, the several flocks, if I may so call them, would have to be regularly herded out and in from their houses to their runs, thus giving extent and change.

Twelve acres out of the thirty round the yard are to be used for the poultry and their runs, leaving eighteen acres for cultivation. We could thus be nearly self-supporting, producing the crops required for our use—namely, barley and oats for our grain crop and straw; cabbages, lettuces—green crop; potatoes, turnips—root crop; and grass for hay and pasturage, giving a proper succession in rotation of crops in batches of six acres, roots and green crop forming one batch.

Finally, seeing what a limited amount of space and accommodation under this system is really required, and that every small holding we might take would necessarily have some sort of outbuildings and sheds, the building capital required need not be over £200, as elegant workmanship in shed-building is not required.

In time, of course, as the breeds become too much crossed we should have to erect a few pens for rearing an annual supply of pure-bred birds to work with. As good eggs and good table birds can only be had by breeding from good stocks, our aim must be ever to keep good breeds to work upon. All further information in the appendix.—G. R. HARRIOTT, *Killmore.*

#### APPENDIX I.

##### ESTIMATE OF EGGS OF 250 HENS.

80 Redcaps	} in all 200 hens at 150 each per annum..	30,000 eggs.
60 Houdans		
60 Brahmas		
50 Cochins, sitting hens, allowed 100 each per annum..		5,000
		35,000
Allow 4000 eggs for breeding from	} 4000 eggs for household purposes, two families	8,000
„ 4000 eggs for household purposes, two families		
		27,000
Deduct losses, 1000.....		1,000
		26,000 eggs for market

20 Ducks at 70 eggs each per annum, 1,400. These all to be bred from.

#### PROFIT ACCOUNT.

	£	s.	d.
Say, then, 26,000 eggs at average 1d. each.....	108	6	8
8,500 chickens at 1s. each.....	175	0	0
88 cartloads of manure at 20s. per cart..	88	0	0
1,000 Ducks at 2s. each.....	100	0	0
50 Geese at 5s. each.....	12	10	0
Add profit on spring chicks and ducklings	17	10	0
For own use, two families—			
4000 eggs at 1d. each.....	16	13	4
500 chickens at 1s. each.....	25	0	0
8 Geese at 5s. each.....	2	0	0
100 Ducks at 2s. each.....	10	0	0
	53	13	4
	£500	0	0

#### EXPENDITURE.

	£	s.	d.
268 hens and cocks at 3s. per annum (food).....	40	4	0
Man and wife to take charge, between them.....	60	0	0
Rent of 30 acres at 30s. each per annum.....	45	0	0
Taxes, &c.....	7	10	0
Interest on capital, say £200 at 5 per cent.....	10	0	0
Fuel, &c., for servants.....	12	10	0
Keep of, say on an average, 1000 chickens at 3s. each per an.	150	0	0
	£325	4	0

Add to the above the produce of eggs from stock hens, also the value of stock hens and cocks at say 2s. each for 268 = £26 16s.; also 25 Ducks and drakes at 2s. 6d. and 7 Geese at 5s. = £4 17s. 6d.; = £31 13s. 6d.

It remains to be seen whether there may not be extra refuse to feed pigs, also surplus crops off the eighteen acres under cultivation to send to market, such as hay and corn. Many of these supposed items may not turn out facts, but I think enough has been shown to infer that there is fair ground to expect that with due care and supervision there should be a fair profit.—G. R. H.

CRYSTAL PALACE POULTRY SHOW.—We understand the entries amount to nearly four thousand. A slight diminution has taken place in the Dark Brahma entries, the Lights are as large as ever, the Dorking classes are also very good. Pigeons show an increase. To expedite the judging Mr. P. H. Jones's name has been added to the present advertised list. The dinner is arranged to take place on Tuesday, the first day of the Show, at five o'clock, and it is anticipated that it will assume the same leviathan proportions the Show has done. J. K. Fowler, Esq.,

of Aylesbury, will take the chair. Tickets and every information can be obtained of the Hon. Sec. We wish it every success.

### MY EXPERIENCE.

ONE rule will not apply to the feeding of all kinds of poultry, because what would produce eggs in the nervous active birds would produce fat in the Asiatics, rendering them useless.

It is this trying to care for all by one rule that has brought into saying, "The big birds eat the most and make the least return." It may be true that they will eat the most if they can get it, but actual experiment has proven to me that an Asiatic is profitable on less than would keep one of the smaller kinds in condition.

As to climate, observation and experiment have also proven to me that poultry in the southern States and California can bear different treatment from those having to endure the changes of season in the eastern and middle States. I think the feeding of corn during the heat of summer is one cause of the dreaded chicken cholera. Corn is heating and hard to digest. During the heated term the system of a bird is wholly relaxed—digestion is very slow. I think the corn produces a fermentation that poisons the blood. Nor is this thought alone—it is the result of careful study, comparison, and experiment.

In the extreme west and south, where, though warmer, the temperature is more equable, birds keep their tone, and corn could be given the year round, and prove neither healthy nor profitable.

My way of feeding my poultry is the result of much experimenting. My object has been to obtain the greatest amount of good for the least expenditure of time and money. In my poultry houses are two bins; one sufficiently large to hold the wheat for at least a winter's use. The other smaller, and used for a mixture of bran, middlings, coarse oatmeal, and, during the winter, corn meal. To this second bin I add one half ounce of best cayenne pepper to every 100 lbs. of meal.

I feed but twice a day, excepting when the birds are confined indoors by winter storms, then I add a noonday meal of cracked corn, whereas always at night I feed only with wheat, and that neither screenings nor damaged grain, but good clean wheat. On the back of the kitchen stove is always a kettle, which my wife calls the "stock-pot." It is washed out every day, and so keeps perfectly clean and sweet. It has a tightly-fitting cover of tin, made on purpose, with one-half which is raised with a hinge, so that it can be opened readily, yet the cover taken off easily, and still the aroma be prevented from passing off with the steam.

Into this kettle all the scrapings of the plates are put, also the potato parings and the waste of vegetables. Into it the water from the boiling potatoes and vegetables is drained. All the odd bits and bones that would otherwise be thrown to the dog, cat, or left to attract rats, find there a place. Leavings of milk, in fact everything eatable that would otherwise be thrown away goes there. If odd bits of meat and bone are not plentiful the order to the butcher includes a few cents' worth of waste meat or a sheep's pluck. As I said before, the kettle is on the stove all day, and after dinner, if it is not already full, boiling water is added to bring the contents within 2 inches of the top. Of course by night the "soup" is thoroughly cooked. When the fire is made in the morning the kettle is put over the blaze and its contents very soon are scalding hot. I then empty it upon a pan of the mixed meal I brought in the last thing at night, mix thoroughly, and take to my chickens, dogs, and cat for their breakfast.

I have certain places in each run where I feed in the morning, and once a week I make upon those places bonfires, into which I rake the bones that have accumulated through the week, adding a few oyster shells, thus removing the litter, and furnishing charcoal, calcareous matter, and ashes to my poultry. It is curious how little will be left of the ashes after the birds have rolled in and picked them over. As soon as I have emptied the kettle it is washed, and with a little water put in again is placed upon the stove, ready for the scraps that might come from the breakfast. To be sure this looks like a little trouble, but it is like everything else where there is system; working by rule, it all comes in right and easy.

A neighbour of mine was troubled very much by feather-eating fowls. He says he found his remedy in pounded borax, which he discovered by a mere accident. He had been pounding some borax in a wooden box, and leaving it for a few moments he found his Black Leghorns eating it greedily. Afterwards, seeing it did them no harm, he furnished it to them, and very soon after feather-eating ceased entirely. Query, what did the birds find in the borax that satisfied the craving that they had had before for the feathers or blood? You've noted a great many remedies in your paper for vermin, but I have not seen a mention of carbolic powder. I have used it and found it perfect as both disinfectant and vermin-exterminator. I merely dust it through the feathers of a bird, using a common flour dredge. With that so applied, with coal oil used freely over the roosts,

by burning out the nests of sitting hens after each hatching, by whitewashing twice in the twelve months, and making a smudge once, I have kept my premises perfectly free from vermin of all sorts.—E. STOWELL.—(*American Fanciers' Journal*.)

### DERBY SHOW OF POULTRY, &c.

THE ninth Show of the Derby Ornithological Society was held on the 4th and 6th inst. in the Rifle Drill Hall, which is without doubt one of the best places in the kingdom for such a purpose, the light being equal and good. The entries were good—650 in all, but several classes had been taken off, else they would have been much larger. Turner's pens were used, and well placed in single tier. Spratt's foods were used, and with an ample staff of Stewards and a Committee of real fanciers, who face real work with earnestness, the whole was well managed.

*Dorkings* were first, and a good class, while the *Cochins* were better. The first old Buffs, second a grand pen of Partridge chickens. In Dark *Brahmas* first was carried off with a famous hen and a cockerel, the rest being young birds. Lights not so good as Darks, chickens winning; the third cockerel rather cloudy on the wing, but a grand pair otherwise. *Game* were single birds. In Black Red cocks first was a chicken, a gem all through; second young also, but rather rakish; and third a substantial old bird, but not up in feather. Brown Red cocks not equal, but there were two very promising undubbed cockerels. Black Red hens, as a lot, were very rough, but the first pullet was an exquisite bird, second a large substantial hen, and third a pullet, which needs making-up a little. In Brown Red hens first and second were gems, and both of this year; the third an old bird. In the Variety class Piles won all the prizes; one Duckwing, very good in all other points, was crooked. Hens, Pile first and third, and Duckwing second. *Hamburghs* had but two classes. In Pencils first were very good Silver-pencils; the cockerel had a capital tail; the second Golden. One pen of Golden (Hallam) had by far the best pullet, but the cock was ill. In Spangles first and third were Golden, and second Silvers. The first a very good all-round pen, and in nice order. The Silvers were only priced at £2, and were sold. *Bantams*, Game Reds were poor if we except the two pens of Black and Brown Reds, first and second, and in the next only the first Duckwings were of any quality. In the Variety of Bantams first and third were Black, and second White Booted. In the Variety class first were a capital pair of Golden Polish, second and third Spanish.

In *Pigeons* Carriers were first on the list, a good all-round Black cock winning, his neighbour, perhaps a better bird, not yet in bloom, was a Black of splendid beak and wattle; second a Black cock, a little flat-wattled; and third a Dun hen. In Pouters *Messrs. Watkin's* White was again to the front. *Dragoons* were a large class; first perhaps the best Silver in the fancy, second a Blue, and third a Yellow; a better Yellow (Wood) was altogether down, and its feathers the wrong side up. In Antwerps were a mixed class; first a Red Chequer, second a Silver Dun, and third a Red Chequer, all Short-faces. Fantails a grand lot and showing well, and well placed as regards position for judging. In Turbitts all the prizes went to one lot; the second to a capital Black bought in the Selling class at Mansfield the previous day. Tumblers, first the Mansfield cup hen, and second the cock, as also the Red Whole-feather third. In the Variety class first was Mr. Yardley's Black Barb hen, second a capital Red Jacobin, and third a Pigmy. In the Selling class first was a grand Red Swallow, second a Black Carrier hen, and third an Almond.

## MANSFIELD SHOW OF POULTRY, &c.

The first Show was held at Mansfield in the Town Hall on the 3rd inst., and for a first attempt was a great success. The space being limited many entries were refused acceptance, and those accepted had to be placed three tiers high. Turner's pens were used, and the birds well fed with Spratt's food.

First came the *Dorkings*. The pullet in the first pen was a grand bird; all were Dark Grey except the third-prize cockerel, which was more of a Silver, but otherwise by far the best in the Show. *Game*, *Black Reds*, a good lot and well placed, as also the *Brown Reds*, the first of which we thought entitled to the cup in place of the *Duckwings*, which we thought too long-bodied. *Dark Brahmas* were good, chickens taking the prizes; while in the *Light variety* we saw nothing striking. *Buff Cochins* were very good; and in the following class *White*, *Partridge*, and *White* won the prizes. *Spanish* poor except the winners; the second, priced at only £2, were quickly claimed. *French* were a capital class. *Hamburghs* were good as far as we could make out, but these were very badly placed for light, as were also the variety of *Bantams*, in which the pen of *Duckwings* (put third at Southwell on account of the legs not matching) were placed first, the Judge declaring his inability to see the colour of the legs at all. *Red Game Bantams* were poor except the first-prize pen and one of *Brown Reds*.

*Pigeons* were much better placed as regards light, but many were placed too high to look well. First were *Carriers*, a capital *Dun* hen taking the lead, second a *Black cock*, and third a *Dun* hen, which, however, is rather stiff-winged. *Pouters*, first a grand *White cock*, in fine play; and second and third *Blacks*, also good, but not quite in full feather. *Tumblers*, first-and-cup for the best bird in several classes a capital *Almond* hen, second a *cock*, and third a *Red Whole-feather*. *Long-faced* were first a *Black Baldpate*, second a *Yellow Mottle*, and third a *Red Mottle*. In *Barbs* all the prizes went to one loft. *Dragoons* were but moderate classes, not so good in fact as we expected to find; in *Blues* the fault laying mostly in unsoundness of colour. In *Jacobins* the winners were very good and all *Reds*. This class has improved very much of late. *Fantails* were a wonderful class, but were placed sadly too high to be seen to advantage; the cup for the section being awarded to a very showy little hen, which, however, did not show to the same advantage on the following day when placed under the eye, and was consequently beaten with birds only highly commended the day before. *Turbits*, *Blue or Silver*, first a *Blue*, a very neat bird in all points, as also the second; the third being a *Silver*. Any other colour, first a *Black*, which ran hard for the cup, but has part half grown black feathers in the thighs; second a neat *Red* hen, and third a *Yellow*. *Owls*, *English*, an immense class, and two extra prizes awarded. In the *Variety* class first was a neat *White*

Owl, second and equal a *Pigmy Pouter* and *Swallow*, third and equal *Pigmy Pouter* and *Magpie*. Mr. Woods did not show for competition; but few pens were empty.

**POULTRY**.—**DORKINGS**.—1 and 3, Mrs. Arkwright. 2, J. Stott. *GAME*.—*Black Reds*.—1, T. Wright. 2, E. Winwood. 3, J. Calladine. *Brown Reds*.—1, T. Mason. 2, G. Silvester. 3, S. Salter. 4, O. J. Moulds. *vhc*, O. Mason, H. Parker.

**JUDGES**.—*Poultry*: Mr. J. Dixon. *Pigeons*: Mr. E. Hatton.

## READING COLUMBARIAN SOCIETY'S SHOW.

THERE have been manifold discussions into which we have never entered as to the desirability of having special classes for amateurs alone at the great Pigeon shows. The amateurs seem settling the matter in the most quiet and practical manner by establishing columbarian societies all over the country, which hold shows and there exhibit their best specimens, and invite a public inspection of them. The Reading Columbarian Society has not been long established, but already it is a flourishing one, having for its specialité Homing Pigeons. Its annual Show was held on the 2nd inst. at the West Street Hall, Reading, where several hundred excellent birds were shown. They were shown singly and in pairs.

First came young birds of various kinds singly, then Homing Antwerps of many colours singly, and lastly pairs of various kinds of any age. *Carriers* (young) came first. The winners were all *Black*. First was fine in carriage and very long in beak; we thought his gullet excessive. Third a very nice bird too. *Dragoons*.—Two prizes only were awarded, both to nice *Blues*. *Turbits*.—The winners were all *Blue*. The first was a pretty good specimen, but we cannot commend the class. *African Owls* were excellent, all from one loft, and all *White*. After these came the large and well-filled classes of Homing Antwerps. The awards in these classes are, as it were, always provisional, for the birds' merits lie in their deeds and not their appearance; still there are some signs which indicate an active and a useful bird, and these seemed, as a rule, highly developed in the winners. The pairs followed the Homing birds. *Carriers*.—First *Blacks*, second *Duns*, third *Blacks*. The first and second belonged to the same exhibitor, and we must say we much preferred the second, as, we believe, does he; the third *Blacks* were also good. *Dragoons*.—We regretted to see two cocks in several pens in this class. We must say we did not agree with the awards in this class, but then Dragoon-judging is so much a matter of taste. The winners were all *Blue*, and we thought the second-prize pair far too Carrier-like. Mr. Flanagan's very highly commended pair were apparently young, and, if so, very good. *African Owls*.—The pairs were as good as the single birds, first being lovely birds indeed. *Turbits*.—First were *Silvers*; the cock a good and well-known bird; his beak has an unfortunate look, as if it had partially been abstracted. Second fair *Blues*, third poor *Shell-crested Yellow*. *Selling Class*.—First were a fair pair of *Yellow Jacks*, second *Black Carriers*, and third *Black Magpies*. We give the prize list as far as we could make it out, but as there was no catalogue, and the awards were posted up a little irregularly as to the classes, we must beg pardon should there be any error in it.

**PIGEONS**.—**CARRIERS**.—*Single*.—1 and 2, G. Webster. 3, W. G. Flanagan. **DRAGONS**.—1 and 2, W. G. Flanagan. **TURBITS**.—1, 2, and 3, G. Webster. **OWLS**.—*African*.—1, 2, and 3, J. ### MOVEABLE VERSUS FIXED COMBS.

MR. J. E. BRISCOE of Albrighton has lately given us an account of his success in bee-keeping with a Stewarton hive, and made some remarks on straw and bar-frame hives. His success has been very remarkable and gratifying, and I trust that the model he has held up to view will be copied if not excelled by other apiarists. It is encouraging to know that Mr. Briscoe has taken 144 lbs. of super honey from a Stewarton hive in 1876. The "RENFREWSHIRE BEE-KEEPER" has also been very successful this year with a hive of the same kind and managed on the same system of storifying. The total amount of super honey which he obtained was great and encouraging. I am thankful for the reports of their success, and hope that the readers of the *Journal* will be favoured with reports of future success equally stimulating.

In contrasting the straw hive with the bar-frame hive I fear Mr. Briscoe has suffered his enthusiasm to carry him a little beyond the line of fair dealing. He says—"Although all the scientific apiarists of Europe and America have adopted some modification of the bar or bar-frame hive, it has at length been discovered that a large straw skep with fixed combs, made doubly secure by transverse sticks, and the ultimate destruction of the bees by sulphur (which is in the majority of instances involved in this mode of management) to obtain their treasures, is the *non plus ultra* of bee-keeping when large harvests of honey and wax are to be secured." It pains me exceedingly to quote this sentence, and I am sorry that Mr. Briscoe has written it, for the readers of the *JOURNAL OF HORTICULTURE*, if not all the advanced bee-keepers of Great Britain, know that the discovery (if it is a discovery) which he alludes to is about one hundred years old, and that I am neither an advocate nor a patron of sulphuring bees. Another enlightened apiarist, who well knows that I have done more perhaps than any other person in these realms to expose the folly of destroying bees by sulphur, has tried to connect my name and system with the brimstone pit. It is too late in the day for anybody to succeed in such attempts. The destruction or disuse of the sulphur pit is only a question of time, and I am sure if Mr. Briscoe and others will come to our aid in trying to stamp it out of existence they will do some real service to bee-keeping. Many misleading remarks about me and what is called my system I let pass without noticing them publicly, and it has been with considerable reluctance that I have now noticed Mr. Briscoe's remark, and I sincerely hope that it will not be necessary for me to do so again.

I now come to notice the argument of his letter and the comparison he makes. Is it a fact "that all the scientific apiarists of Europe and America have adopted some modification of the bar or bar-and-frame hive?" In a recent number of this *Journal* Mr. J. H. Eldridge of Norwich informs us that he "recently received a letter from an aged Swiss clergyman, M. de Gélien, a bee-keeper of great experience—sixty years, a son of the author of '*Le Conservateur des Abeilles*.'" This Swiss clergyman, in answer to Mr. Eldridge's letter says—"The great question of the day in our Switzerland, as in France, Germany, and America, is that of mobilism or fixism—*i.e.*, moveable or fixed combs. Mobilism has the incontestable advantage of offering facilities for theoretical experiment and the formation of artificial swarms; but is it superior or even equal to fixism with regard to the production of honey? I doubt it a little, because bees do not like to be disturbed in their labours, which always occurs more or less when moveable frames are used." If this Swiss gentleman is correct the bar-frame system is on its trial in Europe and America, and it is a question whether it be finally adopted or not. Meanwhile I should be glad if many who use straw hives would introduce the bar system for the sake of experiment, and give it a fair trial. Some of my friends have already done so, and now cling to the straw hive with greater confidence than ever.

In some few instances to my knowledge the Stewarton hive has yielded grand results, and I am not aware that I have ever written or spoken a word in condemnation of it. Some six years ago I suggested an enlargement of this hive, and this suggestion, which appeared in the pages of this *Journal*, gave great offence to a gentleman who sells the Stewarton hive. In 1864, if I remember rightly, the "RENFREWSHIRE BEE-KEEPER" favoured the readers of our *Journal* with an account of his success that season with a Stewarton. The late Mr. Woodbury sent the number containing this account to me. The results were so great that my faith staggered on reading them, but believing every word of the report of the Renfrew success, I set myself to the task of comparing it with results obtained in an adjoining county—namely, that of Lanark, in the same year. I remember I found it very difficult to decide which was the greater success. At Carlisle, in Lanarkshire, the late Mr. Reid obtained from a stock hive a gross weight of 328 lbs. in 1864. The old hive was 96 lbs.; first swarm, 160 lbs., and second swarm was 72 lbs. These, of course, were in straw hives. Since 1864 I

have been gathering the best results of the system and presenting them annually to the British public. In 1874 Mr. Geo. Campbell, in Aberdeenshire, had a gross return of 373 lbs. from a stock hive. All argumentation and advocacy in favour of this or that hive, or this or that system, will not go far without facts or results. It is well known that facts remain facts whatever may be said of them; and if I have been a successful advocate of the straw hive I owe my success to the facts of the system. Mr. Briscoe has told us what his Stewarton hive did in 1875, "the worst season known for twenty years." It gave about 30 lbs. of fine honey. Surely Mr. Briscoe has not forgotten that a straw hive gave Mr. George Fox a super of honeycomb 86 lbs. weight, which beat all comers at the Crystal Palace Exhibition of 1875.

Mr. Briscoe says that "Mr. Pettigrew justly observes that bar-frames can never help bees, but seems to have failed to discern that they do most materially help bee-masters." I have not failed in this matter, for I have often frankly and freely said that bar-frames are very useful in scientific research and for taking a bar of honeycomb now and then. Mr. Briscoe's admission that they cannot help bees covers the whole ground that I contend for, and I fancy that some of his school will not be quite satisfied with his admission. One thing Mr. Briscoe and others should bear in mind, that supers of honeycomb are not sought by all bee-farmers. Many of the best and most scientific bee-farmers keep bees for honey, not for honeycomb. In Glasgow, where most of the octagon boxes of comb from the Stewarton hives are sold, there is a demand for twenty times more run honey than there is for comb. If Mr. Briscoe lived in the neighbourhood of Glasgow, the best market in the world for run honey, would he condemn the hives and system that helps greatly to meet the demand? We have no demand for honeycomb in this neighbourhood to be compared to the demand for run honey. My run honey sells as fast as it is jarred up at 1s. 3d. per lb. There is a great deal to be said on both sides. I commend the consideration of the subject to the bee-keepers of Great Britain. It is an important question, and cannot well be too fully discussed; and I do not see why the question cannot be discussed calmly and fairly without the use of personalities and misrepresentations. Let us all do what we can to spread knowledge, and thus dispel darkness.—A. PETTIGREW.

### BEEES AND THEIR STORES.

This time last year we were all bewailing the unhappy condition of our hives, which, left to themselves, were more than usually populous and poverty-stricken. Now we are equally unfortunate in a contrary state of affairs—bees few and combs full of honey. Nothing could more thoroughly exemplify the advantage of frame hives over those with fixed combs. My own hives, from which I took all the honey two months ago, have now teeming populations and abundance of brood in all stages, and are well provisioned for the winter—the result of continuous feeding. Some straw skeps which I had an opportunity of examining a few days ago, and which had been left undisturbed, I found full of honey, few bees to consume it, and no brood. The cause was evident—the workers had brought home so much honey that little room was left in the hive for breeding; and as this has been the case ever since June or July, it follows that the population could not possibly be numerous, all the bees born prior to that time having been long since dead.

The prospect for the future is not encouraging, the survival of the stock till spring being mainly dependant on the number of young bees reared; and this again (food being abundant) at all times is ruled by the space of comb-surface which the congregated bees can keep warm. Conditions being favourable the queen will breed all the year round. I have noted brood in my hives during every one of the last twelve months. The prudent bee-master will do well to assist his stocks to attain the condition most favourable to increase, for without young blood the stocks must perish, as every bee now in the hives, except the queens, will, in the natural order of things, be dead before the flowers of May appear. Mr. Pettigrew, I know, disputes this, but any observant man who has worked with Ligurians cannot fail to have had positive proof of it by the total change of variety which invariably takes place on the substitution of an alien queen. I yesterday (November 1st) introduced in my apiary eight Ligurian queens to black stocks, and have not a shadow of a doubt that, provided the stock survives, by May every bee in the hives will be gay with the golden bands. The maxim that "unity is strength" is a very valuable one for bee-keepers. Two weak stocks now separate will surely die, united they will probably live and increase. Therefore I say, See to your stocks, and if necessary make what may seem a present sacrifice into a future benefit by uniting them.—JOHN HUNTER, *Eaton Rise, Ealing*.

On the 27th ult. at Abbot's Hill, Hemel Hempstead, on the invitation of the Rev. Herbert Peel (a nephew of the great statesman), at a harvest festival, Mr. John Hunter gave to the

tenants, labourers, and visitors a lecture on bee-keeping. The day being exceptionally fine, Mr. Hunter was enabled to illustrate his lecture by practical demonstrations of the methods of driving and transferring a stock of bees from a straw skep to a frame hive. The impunity with which the bees were handled greatly astonished a large audience of rustic bee-keepers.

### BARLEYSUGAR FOR BEES—POLLEN.

I WILL endeavour to answer the questions put to me by your correspondent "O. B.," taking them in the order in which he places them.

1st, "What kind of barleysugar did I administer?" I make my barleysugar thus—I put a wineglassful of water, half the same quantity of vinegar, and a pinch of salt into a stewpan, adding to this 3 lbs. of good loaf sugar ( $3\frac{1}{2}$  d. per lb.). Sometimes I make a greater quantity at the time, but these are the proportions. I place the pan over a bright fire, and keep its contents stirred for about fifteen minutes—that is, until all the sugar is melted, and boils well. I then draw it a little way from off the fire, and keep it gently simmering, and above all constantly stirred. Soon a crackling noise proceeds from the boiling. I then try a drop or two on a cold plate. If it becomes solid and brittle the sugar is sufficiently cooked. I pour the liquid into ordinary shallow tin dripping-pans, so that the cakes will be about half an inch thick. The liquid sets in a short time, and with a sharp rap at the bottom of the tin, or by banging it down bottom upwards on a board, the barleysugar is at once emptied out and broken into suitable pieces. I have always put it at once into air-tight vessels. Pickling bottles will do. If exposed to the air it will liquify.

2nd, "In what form and in what way is the barleysugar administered?" The pieces as broken by the method stated above I give to my bees by placing a piece of perforated zinc or small-meshed wire netting over the central hole above the hive, or in the quilt, and I use a flower-saucer, small biscuit-tin, finger-glass, or flower-pot to cover it, wrapping all up warmly again afterwards.

3rd, "What is the cost?" Made as above,  $3\frac{1}{2}$  d. per lb. If bought, 9d. per lb.

4th, "With regard to artificial pollen, &c.?" This is simply pea flour bought from any grocer for 2d. per packet. The best way to administer it is by adopting Mr. Abbott's plan, which is to place some clean deal shavings in a skep and to scatter the contents of a packet over the shavings. To allure the bees at first to it, put a piece of recently burnt honeycomb in the skep. I have placed a sheet of glass over the skep, leaving slits at the side as entrances, and the skep has been placed in a sunny corner. Thousands of bees will enter this skep, coming out of it like millers white with the flour.

5th, "Can anyone say from experience if the same results could be produced by feeding, and omitting the pollen?" In former years I fed, but only used the artificial pollen this spring for the first time. Young bees were most numerous with me both early last season and this, but their numbers this year from individual hives far surpassed those of last year. I may or may not be right, but I attribute much to the good results arising from a supply of baby food being early and constantly carried home. This influx must excite the queen's egg-laying propensities as much as the sight of food for the adults.

6th, "Will not the ivy pollen now being collected supply the spring wants?" To this I can only answer, that just as a hive with many pounds of stored honey is still idle, and its queen unproductive far into the spring, incoming pollen retards the prosperity of the hive. How eagerly the bees seek out and collect every grain from the earliest flowers. As soon as there is at all an abundance of natural pollen the artificial flower is entirely disregarded. As many of my hives have been newly filled with combs taken from skeps, I have out those with plenty of pollen and equally distributed them, and my bees now amuse themselves on fine days by carrying off the pea flour from a skep under shelter of a large cart shed. The ivy has been in berry here for some time.

One other remark about syrup and barleysugar. I never employ syrup for late autumn or very early spring feeding. For early autumn in rapidly feeding-up weak stocks it is preferable to barleysugar, and, again, it can be given gently when warm spring weather has really commenced, but the superfluous water contained in it is injurious to the welfare of the hive in cold weather. Not only is barleysugar better for the bees, but it is also so much more easily given and cleaner to handle by the master.

Another of your correspondents asks for information concerning Lee's 12s. 6d. hive, and Abbott's 3s. 6d. hive. I have both. Two of the 3s. 6d. hives stood out all last winter, and each gave me over 60 lbs. of super honey this season. But—and the but must be attended to—I wrapped them up very warm, giving them an overcoat of straw-bottle covers, those sent out over wine bottles; these I tied together closely, and tacked them top and bottom to strips of laths. The laths were fastened to the top and bottom edges of the hives, thus leaving a space of air be-

tween the straw and wood. I put some quilts of old carpet over the frames, some dried grass above them, and a wooden roof covered with waterproof felt, and projecting well over hive, and floor-board over all.

I have not yet tried Lee's new 12s. 6d. hive. The roof must first be made waterproof, and similar jackets made for it as those given to Abbott's hives, and then I have not the least fear of placing it out of doors.—P. H. PHILLIPS, *Offley Lodge, near Hitchin.*

### OUR LETTER BOX.

OXFORD SHOW.—Mrs. Pasley, Fareham, informs us that her Silver-Grey Dorkings were "very highly commended," and her Gold Pheasants "highly commended."

EIGHT-TOED DORKINGS (*S. W. J.*).—Dorkings will sometimes come with four toes on each foot, but it is rare among well-selected stock. Silver-Greys are birds of plumage, and sometimes a chicken will be all that is desirable in shape and colour, but will be deficient in toes; nevertheless the defect is overlooked for the sake of other points. It is just the same in Sebright Bantams. Often the best laced bird will have a single comb. Every other point may be unusually good, and the owner dubs her (a wise thing to do), and puts her among his breeding stock. In the case of Dorking and Sebright the defects are sure to be transmitted, and will soon be seen as the birds emerge from chickenhood. But those that are faulty are not the only birds that suffer from defects. Many of those that are perfect have the "bad drop," and will every now and then prove that Nature always vindicates herself, and will not be contravened in her laws. Many people believe the Silver-Greys were made by crossing with Duckwing Game. That would introduce the four-clawed foot. If your birds commonly come with four toes you have some bad blood to get rid of. Do it before another season and substitute better.

INSECTS IN CAGES (*M. H., Castleton*).—You have done quite right in washing the cage, but the insects you have forwarded are harmless to the birds. They vary very much in colour and form to the bug-shaped insects so worrying to cage birds, particularly to Canaries, nor are they the same kind of insects (although much resembling them in colour), which are found upon fowls. It is true you may find them among old books, and very often in the crevices and beneath the sliding bottoms of cages. Those you have forwarded will run about with considerable speed compared to the Canary red mites, which later are slow in their movements, and are at first white or grey, and become red or vermilion after they have sucked the blood of their victims.

### REMARKS.

- 1st.—Fair bright morning; beautiful day, but rather hazy at night.
  - 2nd.—Slight haze in morning, but soon clearing off to fine day, but again hazy at night.
  - 3rd.—Foggy and very cold at 8 A.M., clearing up soon after nine; but followed by a day neither sunny nor wet.
  - 4th.—Rain past night, followed by a rather dull day.
  - 5th.—Rain in early morning; damp and foggy till 10 A.M.; rather better after, but not a bright day at any time.
  - 6th.—Rain in past night; very fine morning; rather dull for a short time about 10 A.M., after then very fine; rather cooler at night.
  - 7th.—White frost, followed by a most beautiful day and splendid start of night.
- High barometer, north-westerly wind, and very fine weather. Sharp frost on the first two nights.—G. J. SIMONS.

### COVENT GARDEN MARKET.—NOVEMBER 8.

LARGE quantities of American Apples are still arriving, and have been sold during the past week at a great reduction upon former prices. Pears are realising high rates, the principal supplies reaching us from Jersey and Guernsey, and consisting of Chamonville, Glou Morceau, and Beurre Diel. Kent Cobs are experiencing a steady fall.

From observations taken near London during forty-three years, the average day temperature of the week is 48.8°; and its night temperature 34.1°.

## A GARDEN OF HARDY FLOWERS.—No. 1.

**I**GNORAMUS" asks for instructions how to plant his garden with flowers so as to insure "a maximum of pleasure with a minimum of future trouble." Gladly do we respond to his appeal, not only because there are many other owners of small gardens to whom such information would be useful, but also that by far too little attention is given to this matter in gardens of every kind, and yet what a mine of floral wealth have we to draw our supplies from! Surely it must be owing to ignorance that the great value and importance of hardy flowering shrubs and perennials have not hitherto obtained the general recognition which they so justly merit. Faulty arrangement has also some influence in this matter, for how often do we see borders of hardy flowers in which the plants are jumbled together without any attempt at effect whatever. Now, this is undoubtedly a mistake; formality may be objectionable, but we would certainly prefer the most angular and stiff design to a confused style totally devoid of expression or a single feature that is graceful or lovely. Let us, therefore, proceed to the consideration of certain familiar parts or features of gardens large and small, and see if we cannot do something towards the promotion of orderly yet graceful arrangements, free from stiffness and formality on the one hand, and confusion and slovenliness on the other.

A gently sloping bank—whatever may be its position, whether at the extremity of a lawn or beside a shrubby walk—affords facilities for a variety of arrangements, any of which will prove just so effective as they are suitable for the position and the size of the garden. In a small garden, where it is desirable to secure as much variety as possible, I would plant the bank with a mixture of dwarf flowering shrubs and perennials. The pink-flowered *Escallonia macrantha* will form a low shrubby tuft in such a situation, and will also spread its trailing growth over any jutting rocks or crags when such are present. *Cotoneaster microphylla* is equally effective in its way, with an abundant trailing growth closely set with stout deep green foliage and rich crimson berries. Then we have *Pernettya angustifolia*, very effective and picturesque, with pink-stemmed branches, deep green foliage, clusters of white Heath-like flowers, followed by a profusion of deep crimson berries. Like the other two shrubs, this shrub is an evergreen, but is not a trailer, the growth being compact, erect, and yet not formal. *Mahonia aquifolia*, allied to the Berberies, is another good dwarf evergreen with handsome glossy foliage, large compact clusters of rich yellow flowers in spring, with deep purple berries later in the year. It forms a large low-spreading shrub in good soil, and is very ornamental. *Berberis Wallichiana* and *B. dulcis* should also have a place here; the first forming very compact dwarf shrubs, and the last, which is of a comparatively loose growth, is an attractive object when bearing its pendant flowers and berries.

No. 516.—VOL XXXI. NEW SERIES.

If peat could be had I would prepare special stations in what appeared to be the most suitable situations, say near the lower margin of the bank, and so be enabled to enrich it with tufts of the sweet-scented *Daphne Cneorum*; the *Andromeda catesbaei* and *floribunda*—quite the best two of this genus; the evergreen Chinese *Azalea amena*; the tall-growing shrub-like *Erica mediterranea*; the bright pink *Erica carnea*, so charming in early spring; the best of the Irish Heaths, *Menziesia polifolia*, which produces a mass of large purple bells throughout autumn and the early winter months; *Kalmia angustifolia*, with its charming varieties *rosea* and *rubra*, both of which I have in flower now (November 2nd); *Skimmia japonica*, with glossy evergreen foliage and bright scarlet berries; and the dwarf *Rhododendrons dauricum* and *ferrugineum*.

Flourishing in almost all kinds of soil and most suitable for the bank are the *Spiraea callosa* and its white variety *callosa alba*, with *S. Thunbergii* and *S. ariaefolia*. The varieties of this charming family are very numerous and constitute an important section among flowering shrubs, but most of the others are somewhat too tall or spreading in habit to be useful here.

With these few but very choice shrubs we may intersperse a certain quantity of perennial flowers, taking especial care to select some for all seasons of the year. The Moutan *Paeonies* are most suitable for such a situation; they are attractive objects when in full beauty, but the brief duration of the flowers renders them undesirable for planting alone. Mingled with other shrubs as they would be here, they burst into beauty in early summer, meeting the eye like a pleasant surprise, which is all the more agreeable from the fact that the plants have not been offensively conspicuous while out of bloom. There are numerous good sorts, from which I select the following choice dozen:—*Cornelia*, *Athlete*, *Elizabeth*, *Lactea*, *Samarang*, *Confucius*, *Emilia*, *Rubra odorata plenissima*, *Morris*, *Osiris*, *Rienzi*, and *Madame Stuart Low*.

*Pentstemons* may also be introduced here advantageously; they are most desirable hardy flowers for beds and borders of most kinds, many of the newer sorts being especially fine. For a choice dozen we may take *Crimson Banner*, *Agnes Laing*, *Sceptre*, *W. E. Gumbleton*, *Cato*, *Delicatissimum*, *Monarch*, *Stanstead Rival*, *W. P. Laird*, *Syrian Mantle*, *Yeoman*, and *Striata*.

Of other flowers we may take *Dielytra spectabilis*, *Columbines*, *Chrysanthemums* to be selected from a list which will be given in another note, the old *Crown Imperial*, and the equally familiar old white *Lily* (*Lilium candidum*), with such *Campanulas* as *macrantha* and *pyramidalis*; the blue-flowered *Statice latifolia*; *Anemone japonica*, a most valuable late white flower, some plants of which I can see as I sit at my desk, having even now several unexpanded flowers which a few hours of genial sunshine would bring out; *Tritoma Uvaria* and its varieties *grandiflora* and *grandis*; *Lythrum roseum superbum*, and some of the *Michaelmas Daisies* (*Asters*), such as *A. elegans*, *versicolor*, *Novæ-belgii*, and *Novæ-Angliæ*. The two last sorts are especially striking with large pink and blue

No. 1463.—VOL. LVI. OLD SERIES.

flowers. I planted a few of each of them last winter and they have proved very ornamental during the past autumn.

Thus much for the decoration of the bank; now a word as to the arrangement of the plants. Take care, in the first place, not to plant too many. Give each plant and shrub ample space to develop its full proportions, for much more pleasure is derivable from a few well-grown specimens than from a host of wretched starvelings. Place some of the tall-growing sorts near the top of the bank, and dot the others among the lower-growing kinds as taste or fancy may suggest. If space can be had for a few groups by all means let them be formed, for they will impart character and importance to what may otherwise appear somewhat trivial and insignificant. If the bank comes down to the margin of a walk we may fringe it with very many dwarf plants, such as Moneyworts, several of the Gentians, especially *G. acaulis*, Cowslips, and all the other hardy *Primula* tribe. A few Lilies of the Valley, too, may peer out among the foremost shrubs, with tufts of the lovely deep blue *Omphalodes verna*; while at other and more open spots Snowdrops, Crocuses, and other bulbous plants may all lend brightness and beauty in their respective seasons.

Let it be understood that here I have the adornment of small gardens especially in view. In large places such a mixed style of planting would not be followed, except for special purposes; we would rather clothe the bank with one class, or even one sort only, of some plant or shrub that is striking or agreeable in a large mass, such as we find in the *Gaultherias*, *Mahonia aquifolia*, *Cotoneaster microphylla*, *Osmunda regalis*, *Vinca major*, *St. John's-wort*, and the *Escallonias*.

If the mixed planting of the bank came down to the margin of a little rill or stream we might impart a novel finish to it by planting *Mimulus*, *Marsh Gentian*, *Moneywort*, and *Myosotis* alongside and in the stream itself, relieving them by such plants of bolder growth as *Iris Pseud-acorus*, the pink-flowering Rush (*Butomus umbellatus*), and some of the narrow-leaved Ball Rush.—EDWARD LUCKHURST.

#### DECIDUOUS TREES AND SHRUBS.—No. 2.

AGRICULTURE and horticulture have appropriated not only all the best land, but nearly all the ground available for profitable cultivation, leaving only that for the arboriculturist which from difficulty of access or other impediment is impracticable of cultivation or not calculated to prove a profitable investment. It is difficult to account for the antipathy of the agriculturist to trees; they are neither valued as shelter from cold, nor as affording shade against heat. Nothing pleases him so much as to see the felling of trees. He will not tolerate trees on his farm if he can help it; and as for having anything growing near his dwelling taller than cereals, it is never thought of but to be avoided. A plantation of trees to him means more "varmint," less grass, less grain, and smaller profit. Lines of trees as hedgerow timber are certainly not picturesque, but a few trees even in hedges are not undesirable. I know the difficulty of cultivating arable land where trees prevail in the hedgerows, and of the impoverishment of the soil so far as the roots of the trees extend, and also of the injury to crops by the shade from overhanging branches; yet with increased size of fields, where two and more have been thrown into one, a few trees might safely be tolerated. Clearly an Oak or an Elm with a clear stem of 10 to 12 feet would not present any serious obstruction to tillage, and such if widely planted at irregular distances would do much to improve the appearance of the district, for even a locality of "high farming" appears sterile when destitute of trees. Probably no part of the country is so barren of trees as that through which the Great Northern Railway runs between Grantham and Hitchin, and yet I greatly doubt if that district is more profitable than others where trees abound in reasonable numbers. Great numbers of trees do not contribute to the beauty of the landscape, but in the distance resemble a "wood,"—very different from scenery with open glades intervening between the masses of trees.

The influx of foreign timber may have done much to discourage the planting of trees, for with a depreciation in the value of home-grown timber it is only likely that the estimation of trees would be lessened by their proprietor. It costs little to fell trees, and by removing some of the hedgerow timber, especially that overhanging small trees, the land will give an increased produce and bear a higher rent; but that is not a sufficient reason why all the trees should be cut down. It is difficult to saddle the right horse with what in many instances can only be looked upon as a wanton destruction of

timber. There is no objection to the application of the axe after a tree becomes of the best value as timber; to leave it after this is to leave it to decay, but there is no reason whatever in clearing the country of trees and planting none. It is as bad or worse than planting everything and felling nothing; and though, as a rule, timber should be turned into money when of the most profitable size or age, yet there are trees which from their associations and stateliness have marked for themselves a distinction above their fellows. These have secured such a hold in the estimation of the public as to be almost venerated. In removing trees, therefore, that are at their best, is it not worth while to spare a few of the better specimens for the benefit of present and future generations? Our historic and ancient trees will not endure for ever, and is the present to have all and the future nothing? Spare, then, some of the grandest and noblest specimens of Nature's ornaments.

I shall not do more than allude to the alleged comparative increased liability to drought from the absence of trees which is found to have resulted in some countries. I do not wish to compare this country with a vast forest, but I am sanguine that the preservation of its natural beauty is not incompatible with a high agricultural cultivation. If it be desirable to fell timber it should be an injunction to plant, not perhaps in the same order so as to impede tillage, but when hedgerow timber is removed what is to hinder a like number of trees being planted in a mass, taking off a portion of land where the fields form angles, and form it into a plantation? That might to some extent encourage game, but as hares and rabbits are being put aside by a majority of sportsmen, there is nothing to apprehend on that head of a character injurious to the agricultural interest; but, on the contrary, an increase of winged game would be valued by almost all landlords and not a few tenants. There is many a strip of land difficult to work which might advantageously be the site of a plantation.

I shall now proceed to offer some remarks upon what is often considered a well-wooded country, because every hedgerow is studded with trees, and woods are neither small nor distant. In a majority of cases of an overwooded district the seats of landed proprietors are located. Is there any beauty in a park studded with trees, which form a "wood" and disguise the mansion? Trees in such places are not unfrequently in lines over the whole of the surface, and composed of the commonest trees of the country. They have not been retained or planted with a view to displaying them in their greatest beauty, nor for enhancing particular views of the surrounding scenery. Parks thus planted exhibit none of the principles of ornamental grouping, the effect of the trees being to curtail the appearance of extent from every point of view.

To improve parks of this character the trees will for the most part need to be removed from the interior, or so as to form glades, having few or no closely-planted masses, retaining those near the boundary so as to form backgrounds to the interior. The trees retained should be so disposed as to give the greatest depth of view, and at the same time not show the boundary in the distance. When the effect of a mass is desired it may be produced on level ground by an open grove of scattered trees. Flat surfaces can only be improved by varying the character of the glades in size and form. Forming glades or vistas would necessitate planting young trees amongst the old, which would add greatly to the variety and beauty of the scenery, remembering to plant at such distances that the trees will show their natural forms.—G. ABBEY.

#### SEEDLING BRIARS.

IN answer to "J. E. B.," I confess that I have not had much to do with Roses worked on this stock except Teas, but I believe that the mode of budding them is precisely similar to that of working on the Manetti. The great point in both cases is to work very low—almost on the roots. On the seedling Briar I should imagine this is more necessary than on the Manetti. I have just received a quantity of Teas on the seedling Briar from Mr. George Paul, which quite electrify me. I never saw such fine roots. I have never tried H.P.s on this stock, but Mr. Reynolds Hole has pronounced it to be the finest of all, and this after a most exhaustive trial. I think "J. E. B.," who lives in the same neighbourhood, cannot do better than consult Mr. Hole.

My own opinion of the stock is, that it is the grandest of all for Teas and such Roses as Marie Baumann, but judging from experiments tried by my friend "Hercules," I do not think it is so good as the Manetti for the ordinary run of Hybrid

Perpetuals. I should certainly recommend the ridge system if the soil is very thin and poor, but not, I think, in good soil. Mr. Cranston and many of our best Manetti Rose-growers never earth-up theirs, but other great growers such as Mr. Keynes do, and he has a wretchedly poor soil.—WYLD SAVAGE.

### USEFUL VERONICAS.

VERONICA BLUE GEM is noted in the Journal of last week as a valuable autumn decorative plant. There can be no doubt whatever that it is highly worthy of note and of cultivation, and few, if any, who have seen plants, as you say, well grown, can dispute their value.

When this plant was first introduced more was claimed for it than was warranted. It was announced as being a continuous summer-flowering bedding plant. It failed to sustain that character. It is not, at least in many districts, a summer-flowering bedding plant; but it is, when well cultivated, an autumn-flowering greenhouse plant of great usefulness.

I know of no other plant in the same season—that is, from October until January, that will give with so great certainty and with so little trouble such a supply of flowers as elegant in form as they are attractive by their sky-blue colour. The flowers of this plant are always welcome for bouquets and for various purposes of room decoration; and they are produced in the greatest profusion on healthy plants, which do not receive the slightest injury let them be cut ever so severely. But not only as affording a plentiful supply of cut flowers is this Veronica worthy of culture, for the plants if not cut are extremely beautiful for conservatory decoration. As forming a fringe for Chrysanthemums these Veronics are distinct and pleasing. They are also different in colour and habit from Primulas, Geraniums, and, indeed, almost all other winter-flowering plants, and hence their value.

I have grown these plants according to both the modes suggested—that is, by retaining them in the pots all the summer, and planting them out and potting them in October. In raising a stock quickly I advise the planting-out system, but when once the plants have attained to the desired size I prefer keeping them in pots. When large plants are planted out they produce such a quantity of roots that they cannot be placed in pots of convenient size; but by keeping in pots the plants can be preserved in a healthy state by rich food and plunging the pots in ashes.

Another useful Veronica is the old *V. speciosa*. In the days of my boyhood this plant was more extensively cultivated and more greatly valued than it is now. It is, notwithstanding, just as beautiful now as then, and equally useful. Large bushes in pots or tubs are extremely ornamental for the decoration of terraces in the autumn, and the plants if placed in a conservatory continue flowering far into the winter. Such plants may also be cut with impunity, and their flowers are always valued for the furnishing of vases, &c. A variety with variegated foliage has become deservedly popular as a back-row ribbon plant in flower gardens. Its variegation is very constant, and plants of this Veronica mixed with *Ageratum* or dark-foliaged plants are extremely effective. Yet of still greater value have I found this plant when grown to a flowering state and employed in the decoration of the conservatory, where the pale blue flowers associated with the white-striped foliage are peculiarly attractive. The plants if supported with liquid manure continue flowering freely almost throughout the winter.

*Veronica imperialis* is also an extremely handsome decorative plant. It is a strong grower, even stronger than *V. speciosa*, and is perfectly distinct in colour from any of its congeners. The colour of this variety is a bright amaranth-red, changing to magenta, the petals, which are prominent, being pure white. The plant grows and flowers with great freedom, and large specimens are very ornamental throughout the summer and autumn. It is highly worthy of cultivation, and should have a place in most collections.

I have still to direct attention to another useful Veronica, one perfectly distinct from those above named, and of more modern introduction. It is probably a French variety, its name being *Mlle. Claudine Villermoz*. I have not seen it in any list except that of Mr. Cannell, from whom I received it. I should not like to be without this Veronica, for it is almost always flowering, and its colour is so rich—a deep indigo blue. Plants flower profusely when in a quite young state, and continue producing flowers with every fresh pair of leaves which the plants make. Plants have been flowering all through the

summer, and did not cease during the hottest weather, and they are flowering still as freely as ever. It appears to be a plant for any season, and is valuable for many purposes of decoration.

These shrubby Veronics strike readily from cuttings of the young shoots inserted in sandy soil and placed in heat. The plants grow luxuriantly if planted out in the summer, and freely if grown in pots plunged in ashes after the manner of Chrysanthemums. If it is desired to keep the plants as dwarf and compact as possible they should be partially dried after flowering, cutting them down early in the spring, and when they commence growing shaking them out, reducing the roots, and repotting after the manner of Pelargoniums. They require a sunny position and plenty of water. They are seldom attacked by insects other than green fly occasionally, and these are easily extirpated by syringing with a solution of soft soap and tobacco water.

Veronics are a very extensive and varied genus of plants, and probably other cultivators may be able to add to this short list some others which are useful for some purpose of decoration in or out of doors.—A SURREY GARDENER.

### THE ROSE ELECTION.

If any proof is wanting of the wide-spread circulation of "our Journal," it may be found in the following incident. A day or two since I received a note from Mr. Ellwanger of Mount Hope Nurseries, Rochester, replying to my request for names of raisers and age of Roses, and giving me the needful information about several. I add it here, that those interested may fill it in in the poll list. It was not till I looked at the direction to reply to my kind informant that I found the letter was from a rosarian in America, at Rochester, who thus through "our Journal" give a kindly greeting across the Atlantic. I confess to being gratified by the kind trouble taken by one so distant, proving that though so many miles separate us, yet "our Journal" is a bond of union and brotherly feeling wherever it circulates, which is pleasant indeed.

In appending the list I am sure I may add the thanks of many Rose-growers in England to my own to Mr. Ellwanger for his trouble in helping to complete the list.

### AMATEUR GRAPE-GROWING.

WHEN in the neighbourhood of Rothbury in September I visited a few of the gardens in that locality. One of them I should like to mention, as an account of it may be interesting to some amateur readers of the Journal, and may stimulate to further efforts in Grape-growing. The place I allude to is Clive House near Alnwick, the residence of D. P. Bell, Esq. Immediately on arriving Mr. Bell conducted me to his vinerias. The principal houses are three span-roofs; one 40 feet, one 66 feet, and one 80 feet in length, all 18 feet wide with sides 3 feet 6 inches high, the height to the apex of the roof being 14 feet. They are ventilated in the usual way—top and bottom. These houses were erected in the early part of 1871, and the Vines were planted in April of that year, and for the last three years they have borne heavy crops. The two smallest houses are planted with Black Hamburgs, and the largest with late sorts—Lady Downe's, Mrs. Pince, Alicante, Syrian, Black Morocco, Muscat Hamburg, and a Black seedling of great promise. Besides this there is a half-span house planted entirely with Lady Downe's, which are now bearing a magnificent crop of fine fruit, the weights of the bunches varying from 1 to 3½ and 4 lbs. This house is 35 feet long and 14 feet wide, and was planted thirteen years ago. The only other glass erection is a curvilinear house 32 feet long, answering the double purpose of a vinery and greenhouse, and was put up seventeen years ago. With this house Mr. Bell commenced his first experiences as an amateur Grape-grower, and

since that time his interest has hardly ever flagged in the culture of the Vine.

During the past season Mr. Bell has grafted some of the late sorts on to Black Hamburgh stocks, with the view of employing one of the houses for winter-cropping purposes, introducing also some newer kinds of Grapes. In this grafting he has been very successful, as only two out of above fifty grafts have failed.

I have seen many good crops of Grapes, but I never witnessed such an extraordinary weight of fine fruit as were hanging in these houses. The Hamburghs wanted a little more colour to make them perfect, but the late sorts were all that could be desired—good-sized bunches, large berries, and well coloured. As proof of what I say in regard to such enormous crops, I may instance that out of one span-roofed house 40 feet long Mr. Bell has this season cut over 730 lbs. weight of Grapes.

The borders of these vineries have been all thoroughly drained—that is, they have a good rubble bottom, with ordinary drain pipes to carry away the water. They are raised above the level of the ground, and are composed of turf taken from a field near the garden, and as it was rather a heavy loam it was well mixed with lime rubbish, bones, charcoal, &c. Mr. Bell is a great advocate for liquid manure, and he has great faith in a change of food for the Vine. I may add that the owner of these Vines himself does all the principal work that they require, so that he is in the real sense of the term an amateur Grape-grower. My motive for writing this is to stimulate others to do the like, as I am certain that Grape-growing if well conducted will repay for any amount of trouble and expense that may be incurred in making a beginning; and, in addition to mere profit, there is pleasure in Grape-growing. I know it is a great source of enjoyment to Mr. Bell when he is relieved from the more pressing duties in connection with his business to again visit his favourites—the Vines.

In conclusion I must admit that I have gained a wrinkle or two from seeing Mr. Bell's Grapes, and also from correspondence that I have had with him, a correspondence arising out of an article in the Journal, and I have no doubt but that more will yet be heard of Mr. Bell's success as a Grape-grower.—JAMES DICKSON, *Arkleton, Langholm.*

### THE ROYAL HORTICULTURAL SOCIETY.

On the 8th inst., as the result of long negotiation and much correspondence, some members of the committee of debenture-holders of the Royal Horticultural Society waited upon the Council of that body at South Kensington with a view to discussion, and if possible, the arrangement of their claims upon the Society or the Exhibition Commissioners of 1851. Mr. De Castro, the Hon. Secretary of the debenture-holders' committee, was present with the members. The position of the debenture-holders is, that under the agreements between the two contracting parties—the Royal Horticultural Society and the Royal Commissioners—they lent £50,000 to be expended on the Commissioners' property in making an ornamental garden at South Kensington, the Commissioners expending the same amount in enclosing it with arcades. In August last Lord Aberdare, the President of the Society, announced at a meeting of the debenture-holders, that in consequence of the inability of the Council to maintain the Society as a paying concern at South Kensington, the security of the debenture-holders was in a perilous position. Subsequently, when applied to by the committee of debenture-holders, the Royal Commissioners refused to negotiate with them save through the Council of the Royal Horticultural Society. Nevertheless, the debenture-holders contended that they advanced their money in the belief that they had the joint security of the Royal Commissioners and the Society. A few days ago the Royal Commissioners addressed a letter to Dr. Hogg, the Hon. Secretary to the Council of the Society, offering to give power to their own committee of inquiry to endeavour to arrive at some arrangement with the Society, under which the lease of the Horticultural Gardens at South Kensington should be terminated on the payment of a given sum to the debenture-holders. Dr. Hogg communicated this offer to the debenture-holders' committee, and the latter, with some debenture-holders, met yesterday morning to consider it, the offer of the Royal Commissioners being, it is understood, less than 10s. in the pound. Some of the debenture-holders had expressed themselves, it appears, determined to stand out for at least 10s. in the pound,

while a very small number thought 20s. in the pound ought to be paid them. But it was stated that for this amount the Commissioners were not liable, for if the Society should "last out" its lease up to 1892, with the still overhanging debenture debt of £50,000, the Royal Commissioners would only have to pay one-half the amount. The debenture-holders' committee met the Council of the Society at two o'clock yesterday, and after an hour and a half's discussion the committee declared the offer of the Commissioners was not satisfactory, and the resolution came to was that the committee should draw up a statement and submit it to a general meeting of the debenture-holders to be called in a week or two. The conference had no result but that, and in the meantime it is taken as inevitable that at the end of the year the Gardens at South Kensington must pass out of the hands of the Royal Horticultural Society, as there are no funds either to keep them up or pay the rent to the Commissioners.—(*Times.*)

### WELLINGTONIA GIGANTEA VAR. PENDULA.

This is the second variety that has occurred of the "Mammoth Tree" of California. The other variety is Wellingtonia

Fig. 63.

*gigantea variegata*, of which many of the branchlets are of a pale straw colour. Of the variety of which we publish a woodcut, Messrs. Little & Ballantyne write to us that "It is a chance production, which appeared among a lot of seedlings six years ago;" and they add that "all who see it admit it to be perfectly unique. At this time we know of no similar tree."

### LATE ROSES.

ANYTHING about Roses emanating from Mr. Paul needs no confirmation; but it may possibly interest some of the many readers of our Journal, especially now we are all taking stock of what we have and what we want in Roses, to hear that

yesterday (November 8th), I had in my garden, in various stages from bud to blossom, blooms on *Maréchal Niel* (a standard), *Gloire de Dijon*, *Souvenir d'un Ami*, *Madame Falcot*, *Climbing Devonensis*, *Marie Crocotte*, *Pierre Notting*, and last but by no means least, that glorious autumnal Rose, *Souvenir de la Malmaison*. I may add for the information of all whom it may concern, that my garden is surrounded by a wall 9 feet high, the soil being naturally light, with a substratum of gravel, and that though the natives of this ancient borough (Bury St. Edmunds), will say it is a very healthy place with a fine bracing air, I have heard strangers call it "beastly cold."—*ST. EDMUND.*
